The present study aimed to evaluate the role of the combination treatment of methylprednisolone (MP) and electroacupuncture (EA) in regeneration of nerve fibers and functional recovery in rats with spinal cord injury (SCI). Female Wistar rats were used for an SCI model by using a weight-drop hammer at levels T10 (spinal cord segment corresponding to the 10th thoracic vertebra). Four groups received different treatments for the study: SCI control, MP, MP and EA, and Sham. The growth of nerve fibers was examined by counting fluorescein positive nerve fibers. The motor functional recovery was evaluated by Basso, Beattie, Bresnahan (BBB) score, and electrophysiology analysis. We found that, compared to MP groups, there were more well-oriented and paralleled fluorescein positive nerve fibers in MP and EA group. Both latencies and amplitudes of the Motor Evoked Potential (MEP) in the combination therapy of MP and EA were higher than MP group. Additionally, recovered hindlimb movements were sustained in most rats in the MP and EA group. Our study indicated that combination therapies could become a powerful treatment for SCI in rats.

1. Introduction

A spinal cord injury (SCI) is damage or trauma to the spinal cord. Patients with SCI usually have temporary or permanent neurologic deficits and disability, including motor deficit, sensory deficit, breathing difficulty, and bowel and/or bladder dysfunction. SCI can be caused by accident, diseases, or degeneration. It is estimated that the incidence of SCI around the world is between 250,000 and 500,000 people every year [1].

Steroids have been used in the management of acute SCI for decades due to anti-inflammatory effects and inhibition of lipid peroxidation [2]. Especially in 1990, the results of the Second National Acute Spinal Cord Injury Study (NASCIS II) showed that high-dose of methylprednisolone (MP) could improve neurological recovery of SCI patients [3]. In NASCIS III, post hoc analysis showed that the motor functions had been improved at least temporarily on MP-treated patients that received 48 h MP compared to 24 h administration [4, 5]. However, high-dose MP in acute SCI can lead to side effects including hyperglycemia, wound infections, delayed healing, gastrointestinal complications, and pulmonary embolism [6]. Therefore, the use of MP in acute SCI patients has been controversial in recent years.

Acupuncture is an ancient Chinese therapy by inserting the needles at certain points of the meridians to cure disease
and relieve pain [7]. Electroacupuncture (EA) is a form of 
acupuncture that involves the application of a gentle pulsating 
electrical current on the specific traditional acupuncture 
points on the body. The procedure can be done with or 
without the use of needles. Previous animal studies have 
demonstrated that EA can promote the differentiation of 
mesenchymal stem cells and regeneration of nerve fibers in 
rats with SCI [8]. Additionally, EA can improve neuronal 
function recovery and inhibits inflammation responses and 
microglial activation after SCI [9].

In the present study, we examined the role of combination 
treatment of MP and EA in axon growth and regeneration and 
hindlimb movement function recovery in rats with SCI.

2. Materials and Method

2.1. Animals Group. Adult female Wistar rats (200–250 g) 
were purchased from the Experimental Animal Center of 
Jilin University. Animals were housed in a standard cage 
with the temperature 22 ± 1°C and humidity of 50%–60%. 
Animal experiments related to the study were approved by 
the Local Ethics Committee for Animal Research at Jilin 
University and performed in accordance with international 
standards for animal welfare. Rats were randomly divided 
into four experimental groups, which each contained 18 
rats; specifically (1) SCI control group: no treatment after 
the SCI surgery; (2) MP group: intravenous injection MP 
30 mg·kg⁻¹ immediately after SCI, repeated once 4 h after 
surgery, and then injected twice per day with 3 days; (3) MP 
and EA group: both MP and Hua Tuojiaji (EX-B2, the Hua 
Tuojiaji point is located in the first thoracic vertebra to the 
fifth lumbar vertebra, each vertebral spinous process by 0.5 
inches), Ming Men (GV4, the Ming Men point is located 
between the spinous processes of the second and third lumbar 
vertebrae) and Da Zhui (GV14, the Da Zhui point is locate 
in that depression below the spinous process of the seventh 
cervical vertebra) acupoints were used in treatment 4 h after 
SCI; and (4) Sham group: vertebral plate was opened to 
expose spinal marrow without SCI. The acupuncture needles 
were 25 mm long and 0.35 mm in diameter. The 6805-II 
electroacupuncture therapeutic apparatus made in Shanghai 
is provided with a positive electrode and a negative electrode. 
EA parameters of 1-2 Hz at 0.3–1.0 mA were used in the 
present study. EA treatment was given once every day for 
6 days, 15 minutes each time. After a 2-day interval, 
the second course started, with three courses in total. All surgical 
procedures were performed under general anesthesia with 3% 
pentobarbital sodium.

2.2. SCI Model. Adult female Wistar rats were anaesthetized 
with 3% pentobarbital sodium. A laminectomy was carried 
out at the T₁₀ (the 10th thoracic vertebra) level to expose 
the spinal segment and then a hammer (20 g) was dropped 
from a height of 30 mm onto the exposed dura mater. After 
the induced SCI, all rats received extensive care, including 
penicillin (80,000 U/per rat) and gentamicin (2000 U/per 
rat), for 7 days and thick, soft bedding in individual cage. 
Manual emptying of the bladders was performed three times 
daily. All procedures were approved and in accordance with 
the Institutional Animal Care and Use Committee guidelines 
at Jilin University.

2.3. Behavioral Testing. Functional recovery was assessed by 
observers that were blind to groups of the experiment and 
graded each animal according to Basso, Beattie, Bresnahan 
(BBB) open field locomotion test [10]. The BBB score was 
determined by voluntary hindlimbs movement towards each 
group.

2.4. Electrophysiological Analysis. Thirty days after surgery, 
six rats from each group were used to study motor 
evoked potentials. Following anesthesia with 3% pentobar-
bital sodium, a midline incision was made on the rat's head 
skin, and the cranium was exposed. One hole was drilled 
for the skull by using a standard dental drill. The sciatric 
nerve was exposed to the left leg. The stimulating electrode 
was placed beneath the scalp, recording electrode was placed 
below hard palate. The MEP was induced and registered for 
evoked potential instrument of Powerlab and biofunction 
experiment system of BL-410 (Taimeng, Chengdu, China) by 
appropriate stimulation parameters.

2.5. Fluorescein Injection. Thirty days after surgery, six rats 
from each group were anesthetized with 3% pentobarbital 
sodium. At the second spinal segment of SCI area, fluorescein 
(FR) (Invitrogen Company, USA) was slowly injected using a 
Hamilton microinjector (Dingguo, Beijing, China) at depths 
of 2.5 mm, 1.5 mm, and 0.5 mm away from the spinal dura 
mater, respectively, on both sides with the spinal cord. 
Four days after injection, the spinal tissue was removed, 
placed at 4°C in 4% paraformaldehyde overnight, and then 
replaced with 5%, 15%, and 30% cryoprotective sucrose for 
90 min, respectively. Specimens were then quickly embedded 
in frozen OCT compound and stored at −80°C. Sections 
were prepared for a cryostat (Leica Company, Germany), 
cover-slipped with glycoegelatin to preserve fluorescence, 
and observed under fluorescence microscopes.

2.6. Statistical Analysis. Statistical analyses of electrophysi-
ology MEP results were performed by single factor analysis 
of variance (ANOVA), and least significant difference (LSD) 
was used for intergroup comparison. Statistical analyses of 
fractional recovery BBB score results were performed by 
the ANOVA of repeated measurement design based on the 
original data by using the SPSS program (version 13.0) 
for Windows (SPSS, Chicago, IL, USA). Differences are 
considered statistically significant if \( P < 0.01 \).

3. Results

3.1. Fluorescein Positive Nerve Fibers. To evaluate the growth 
of nerve fibers after treatment for SCI rats, the FR-positive 
nerve fibers were counted in six rats for each group. As shown 
in Figure 1, no FR-positive nerve fibers were observed in 
the SCI control group. In the MP group, short FR-positive 
nerve fibers (red) were occasionally seen in the proximal SCI 
region, but none of them was distributed over the SCI region.
Evidence-Based Complementary and Alternative Medicine

Figure 1: FR anterograde tagging for spinal cord of coronal plane. Arrow indicates the positive nerve fibers (red): (a) SCI control group; (b) MP group; (c) MP and EA group; and (d) Sham group (bar = 100 μm).

Many FR-positive nerve fibers were found in the MP and EA group, and the neural tracer agents were seen in distal SCI region, which indicated the regenerated nerve fibers extended to the distal SCI region. Compared with other groups, there were more well-oriented and paralleled FR-positive nerve fibers. Many FR-positive nerve fibers were well-oriented and paralleled with each other in sham group.

3.2. Electrophysiology Analyses. To further examine the function of the severed spinal cord after treatment, the MEP was measured. As shown in Figure 2, the rats in the SCI control group showed negligible signal of MEPs. However, a noticeable increase in peak-to-peak valued was observed in the MP group and MP and EA group. Additionally, the rats in the MP and EA group exhibited the highest degree of recovery from both latencies and amplitudes of the MEP, which is similar to what was observed in the sham group.

3.3. Functional Recovery. To evaluate the functional recovery, the BBB score was determined by voluntary hindlimb movement towards each group. As shown in Figure 3, voluntary hindlimb movement was not seen until two weeks after surgery in SCI control group. The rats in the SCI control group were unable to walk while bearing weight. In rats treated with MP, the recovery trend was seen from one week after surgery, but it did not reach significance compared with the SCI control group. In rats treated with MP and EA in the presence, voluntary hindlimb movement was significantly improved compared with the rats in the MP group. In the sham group, the hindlimb movement was seen on day 1 after surgery and almost achieved full recovery one week later.

4. Discussion

Recent studies have found that adult mammalian spinal cord injury leads to a series of neurological deficit symptoms [11, 12] and nerve conduction pathway interruption [13], affecting its metabolism and axonal transport function. Since axonal regeneration depends on this function, structural protein is supplied by the neuronal cell synthesis via axonal transport, and nerve conduction pathway recovery degree directly influences the nerve fiber regeneration situation, it is clear that how to restore the conduction pathway and promote nerve fiber regeneration is the key to the recovery of spinal cord function [14]. MEP mainly reflects the nerve conduction function after SCI. At present, as a more objective and sensitive detection method, it has been more and more used in clinical SCI nerve function evaluation [15]. MEP is a sensitive index to evaluate the functional state of motor conduction pathway, can directly reflect the functional state of spinal cord descending conduction bundle or peripheral motor nerve, and has a strong correlation with lower limb motor function [16,17], and it can effectively detect the degree of spinal cord injury and functional recovery degree after injury [18].

In our study, FR anterograde tagging indicated that many FR-positive nerve fibers were distributed among SCI area and extended to the distal side. Additionally, the nerve fibers were well-oriented and paralleled in the combination therapy of MP and EA. Furthermore, the latencies and amplitudes of the MEP in the combination therapy of MP and EA were higher than those in all other groups. In addition, recovered hindlimb movements were sustained in most rats in MP and EA group. The combination therapy of MP and EA might function via the following mechanism: (1) MP provides multifarious neuroprotective effects, including improving microcirculation, inhibiting lipid oxidation, reducing calcium influxes in cells, and maintaining nervous system excitability; (2) the EA treatment decreases the production of free radicals, regulates neuropeptide secretion, and improves the blood circulation of SCI.

From the clinical and anatomical point of view, it is feasible to effectively restore the neural pathway in spinal cord injury by combining Chinese and western medicine [19, 20]. Electroacupuncture has its unique advantages. EA
Figure 2: MEP wave shape. (a) SCI control group; (b) MP group; (c) MP and EA group; and (d) Sham group. (e) The latency of MEP ($n = 6$; * versus MP group, $P < 0.01$; $\triangle$ versus MP and EA group, $P < 0.01$). (f) The peak-to-peak value of MEP ($n = 6$; * versus MP group, $P < 0.01$; $\triangle$ versus MP and EA group, $P < 0.01$). Statistical analyses of MEP results were performed by single factor analysis of variance (ANOVA), and least significant difference (LSD) was used for intergroup comparison.

Figure 3: Comparison of BBB score of hind limb motor function. $n = 18$; * versus MP group, $P < 0.01$; $\triangle$ versus MP and EA group, $P < 0.01$; statistical analyses of BBB score results were performed by the ANOVA of repeated measurement design based on the original data.
has been shown to be effective against improving functional recovery from SCI patients in traditional Chinese medicine [21]. Animal studies indicate that EA promotes the secretion of neurotrophin-3 and enhances the differentiation rate of exogenous neural stem cells. The therapy of EA promotes the survival and axonal regeneration in rat SCI model [8, 22]. Although there are many problems to be solved, the combination of traditional Chinese medicine and western medicine treatment method will become the focus of research, giving full play to its combined and complementary advantages [23, 24].

In summary, we have presented data that indicate that the comprehensive therapy of EA in rats with SCI can effectively enhance the growth of nerve fibers and improve the hindlimb motor function recovery, suggesting that combination therapies could become a powerful treatment for SCI.
