Background. In this study, the male fertility-enhancing activity of 100, 200, and 400 mg/kg/day of Hunteria umbellata water seed extract (HU) in Wistar rats was studied for 60 days. In doing this, effect of repeated doses of HU was studied on the weight gain pattern, gonadosomatic index (GSI), serum follicle stimulating hormone (FSH), luteinizing hormone (LH), testosterone (TS), prolactin (PRL), and estradiol (ES)}{213} as well as testicular antioxidant status of the treated rats as a way of elucidating the mechanism(s) of action of HU. Method. Thirty-six (36) male Wistar rats were randomly divided into six groups (I-VI) of six rats per group. Group I rats were gavaged with 10 ml/kg/day of distilled water and served as an untreated control; Group II rats were gavaged with 0.3 mg/kg/day of clomiphene in distilled water; Groups III-V rats received 100 mg/kg/day, 200 mg/kg/day, and 400 mg/kg/day of HU, respectively, and Group VI rats received 20 mg/kg/day of Vitamin C in distilled water. All treatments were for 60 days after which the treated rats were humanely sacrificed. Sera of blood samples were processed for the above stated hormonal profile. Similarly, testicular tissues obtained were processed for semen analysis and complete antioxidant profile of the HU-treated testicles by assaying for superoxide dismutase (SOD), catalase (CAT), and glutathione (GSH), glutathione reductase (GSR), glutathione peroxidase (GSH-Px), and Thioarbituric Reactive Species (TBARS). Results. Prolonged treatments with 100 mg/kg/day, 200 mg/kg/day, and 400 mg/kg/day of HU for 60 days induced dose dependent reductions in weight gain pattern with the most significant (p < 0.001) effect recorded with the highest dose of HU. Conversely, significant (p < 0.001) increase was recorded for GSI at the same HU dose. Clomiphene and HU also induced significant (p < 0.01, p < 0.001) dose dependent increases in the total sperm count, % live sperm, but reverse effects on % dead sperm and % abnormal sperm. On the hormonal profile, oral treatment with 100 mg/kg/day, 200 mg/kg/day, and 400 mg/kg/day of the extract induced profound (p < 0.05, p < 0.01, and p < 0.001) dose related increases in the sera TS, LH, and FSH while it caused reverse effect on serum PRL but caused no significant alterations in the serum ES levels. Similarly, oral treatment with vitamin C and 100-400 mg/kg/day of HU induced profound (p < 0.05, p < 0.01, and p < 0.001) increases in the antioxidant enzyme activities. Conclusion. Overall, prolonged oral treatment with 100–400 mg/kg body weight of HU for 60 days significantly improved sperm function which was mediated via enhanced spermatogenesis, steroidogenesis, and antioxidant mechanisms.

1. Background

Infertility is a major public health issue affecting one out of five every married couple worldwide, with approximately 30% of the condition attributable to male factors [1]. It is on records that several factors can interfere with the process of spermatogenesis and reduce sperm quantity and quality with some of the identifiable causal factors being ischemic heart disease, diabetes mellitus, chronic liver diseases, cigarette smoking, agrochemical run-offs, air pollutants, and
hypovitaminosis [2]. However, previous study has reported that regular intake of antioxidants and vitamins such as vitamins A, B, C, and E improves testicular blood barrier stability and protects sperm DNA damage from endogenous oxidative stress resulting from the activities of highly reactive free radicals generated within the body [3].

Male infertility can manifest in the form of premature ejaculation, hypoactive sexuality, erectile dysfunction, oligospermia, azoospermia, etc., but its most common manifestation form is as oligospermia. In treating this condition, testosterone and other forms of hormone replacement therapy are often clinically employed due to their ability to stimulate/enhance sexual appetite in hypogonadal male patients [4, 5]. However, despite the proven efficacy of this replacement therapy in the management of hypoactive sexual desire [6], many patients still prefer to use natural plants because of the attendant undesirable side-effects associated with these hormonal therapies. Two examples of popular male fertility-promoting herbs are Panax spp. (ginseng) and Lepidium meyenii (Maca) which are reputed for their supposed aphrodisiac- and spermatogenesis-enhancing effects [7–9].

Hunteria umbellata (K. Schum.) Hallier f., belonging to Apocynaceae family, is a tropical rainforest tree that is commonly used in the African folkloric medicine to treat human diseases such as blood deficiencies, infections, swellings, diabetes mellitus, and obesity [10–12]. It is known as "Demouain" (in French) and "Abeere" (in Yoruba dialect) (Southwest Nigeria) [11–13]. In Southwest region of Nigeria, water infusion of Hunteria umbellata dried seed is reputedly used in the local management of diabetes mellitus and obesity [12, 14]. Hunteria umbellata water seed extract (HU) of the plant has been reportedly used to effectively control blood glucose and glycosylated hemoglobin concentration in types 1 and 2 models of drug-induced hyperglycemic Wistar rats [12, 14] with its alkaloid content implicated for the observed biological effect [15]. The same plant seed extract was also reported to possess antiobesity and antihyperlipidemic effects in experimental models of hyperlipidaemia which was mediated via de novo inhibition of cholesterol and triglyceride biosynthesis [16]. In addition, the acute, chronic, and reverse oral toxicity studies of HU have shown it to be relatively safe [12, 17].

Recent ethnobotanical survey conducted among selected Ijebu herbal practitioners in Ogun State (Southwest Nigeria) revealed that HU also has a wide application in the indigenous management of infertility (unpublished data). Despite this folkloric use, there are no scientific reports to either validate or refute this folkloric claim. More so, chronic oral toxicity and toxicity reversibility studies of HU have shown it to induce profound proliferation of spermatogenic primordial, Sertoli and Leydig's cells in the testicular tissues of extract-treated rats [17]. Similarly, HU has been reported to possess antioxidant and free radical scavenging properties mediated primarily by its alkaloid content [18]. Thus, this study was designed at evaluating the effects of chronic oral treatment with 100, 200, and 400 mg/kg of HU on body weight, gonadosomatic index, and semen parameters of male Wistar rats treated for 60 days. In addition, effects of HU oral treatment on the complete antioxidant enzymes system [superoxide dismutase (SOD), catalase (CAT), and glutathione (GSH), glutathione reductase (GSR), glutathione peroxidase (GSH-Px), and Thiobarbituric Reactive Species (TBARS)] of treated rat testicles as well as its effect on serum testosterone (TS), luteinizing hormone (LH), follicle stimulating hormone (FSH), prolactin (PRL), and estradiol (ES) were evaluated.

2. Methods

2.1. Plant Material Collection and Identification. After plant identification and deposit of voucher specimen were done as earlier described by Adeneye and Adeyemi [12], eight (8) ripe Hunteria umbellata fruits were freshly harvested from the deciduous forest of Odorasanyin District of Ijebu-Ige in Ogun State, Nigeria, in the months of July-August, 2016. Collected fruits were cut into pieces and their fresh seeds were rinsed generously under a running tap water and air-dried at room temperature (25 ± 1°C) for 1 month, protected from direct heat and sunlight. The dried seeds were milled using Laboratory Hammer Mill in the Pharmacognosy Department, Faculty of Pharmacy, University of Lagos, Idi-Araba, Lagos. The milled sample was preserved in a water- and air-proof container and stored at 4°C.

2.2. Aqueous Extraction Process. 50 g of milled seeds of Hunteria umbellata was soaked in 500 ml of distilled water and kept in the refrigerator for 72 hours. The solution was then completely air-dried in aerated oven preset at 40°C resulting in a deep brown, sweet-smelling solid residue (HU). This procedure was repeated 9 more times and the residues were pooled into a water- and air-proof container and stored in the freezer at -4°C to prevent HU from decomposing.

2.3. Experimental Animals. After an Institutional Ethical Approval on the Use of Experimental Animals was obtained, thirty six 12-14-week-old male Wistar rats weighing between 220 g and 250 g were obtained from Bayo Farms, Sangotedo, Ogun State, Nigeria, and housed in the Animal House of Lagos State University College of Medicine for acclimatization for 14 days. While being acclimatized, rats were fed with standard rat chow and tap water ad libitum and maintained at standard laboratory conditions (12/12 hour light-dark periodicity; temperature: 23–26°C and 40–50% relative humidity) as prescribed by the United States National Institute for Health [19]. Two days to the commencement of the animal experiment, rats were randomly allotted into 6 groups of 6 rats per treatment group such that the weight differences within and between treatment groups do not exceed ±20% of the average weight of the rat sample population, respectively.

2.4. Treatment of Rats. Thirty six (36) male Wistar rats of proven fertility were divided randomly into 6 groups of 6
animals each and their oral treatments per group were as follows:

Group I: 10 ml/kg of distilled water/day for 60 days.
Group II: 0.3 mg/kg/day clomiphene in distilled water for 60 days.
Group III: 100 mg/kg/day HU in distilled water for 60 days.
Group IV: 200 mg/kg/day HU in distilled water for 60 days.
Group V: 400 mg/kg/day HU in distilled water for 60 days.
Group VI: 20 mg/kg/day of vitamin C in distilled water for 60 days.

2.5. Body Weight Measurement. Rat body weights were measured using digital Mettler weighing balance and values obtained recorded a day prior to commencement of the experiment, biweekly during the treatment period, and on the last day of the experiment.

2.6. Calculation of Gonadosomatic Index (GSI). The testes and their cauda epididymis were identified, removed, and weighed and immediately fixed in Bouin’s solution for morphometric study. The gonadosomatic indices were calculated as follows:

\[
\text{GSI} = \frac{\text{testes weight} + \text{body weight}}{100} \times 100 \quad \text{[20]}
\]

2.7. Hormonal Assays. The testosterone level in the serum was estimated by radioimmunoassay (RIA). The assays were performed using commercially available kits (Diagnostic Products Company, Los Angeles, CA, USA). All samples were run in the same assay period. The within assay variation was 5-5% while the sensitivities of the testosterone assay was 8 ng/ml. Sera FSH, LH, PRL, and ES levels were measured by immunoradiometric assay (IRMA) in solid phase also using commercially available kits (Diagnostic Products Company, Los Angeles, CA, USA). The within assay variation was estimated by radioimmunoassay (RIA). The assays were performed using commercially available kits (Diagnostic Products Company, Los Angeles, CA, USA). All samples were run in the same assay period. The within assay variation was 5-5% while the sensitivities of the testosterone assay was 8 ng/ml. Sera FSH, LH, PRL, and ES levels were measured by immunoradiometric assay (IRMA) in solid phase also using commercially available kits (Diagnostic Products Company, Los Angeles, CA, USA).

2.8. Preparation of Semen Sample for Analysis. On day 61, the rats were euthanized with inhaled diethyl ether and a longitudinal surgical incision along the scrotal raphe and scrotal septum was made to expose the testes and its epididymis. The epididymis was freed from the adhering fat and connective tissues. The left epididymis was collected, weighed, and cut at the distal end using a clean surgical blade. Cauda epididymis (100 mg) was gently minced with glass rod without damaging the tissue into 5 ml of 0.9% NaCl [21].

2.9. Semen Analysis for Motility, Count, and Morphology. Complete semen analysis to determine progressive motility, count, and morphology was done in clean Neubauer’s haemocytometer counting chamber under its cover-slip using the method of Amman [21].

Number of sperms per cauda epididymis was calculated as follows:

\[
\{\text{Mean count} \times 50\} \div \{0.01 \times 0.01\}
\]

2.10. Estimation of Testicular Reduced Glutathione Levels. In determining the testicular GSH level, testicular tissue homogenate in 0.1M phosphate buffer at pH of 7.4 was processed through the procedure described by Shaik and Mehvar [22].

2.11. Estimation of Testicular Tissue SOD and CAT Activities. Testicular tissue SOD and CAT activities were estimated using the method of Zhang et al. [23] and Iwase et al. [24], respectively.

2.12. Data Analysis. Data obtained were presented as mean ± S.E.M. of six observations. Data were analyzed statistically using One-way analysis of variance on SYSTAT10.6. Post hoc test was done using Student’s t-test and levels of significance were considered at p<0.05, p<0.01, and p<0.001.

3. Results

3.1. Water Extraction. Water extraction of milled *Hunteria umbellata* dried seeds produced a deep brown, sweet-smelling solid residue weighing an average of 7.33 ± 0.32 g with a %yield of 14.66 ± 0.65%.

3.2. Effects of Oral Treatments with Clomiphene, Vitamin C, and *Hunteria umbellata* Water Seed Extract on Rat Body Weights. Repeated oral treatments with 100-400 mg/kg/day of HU induced significant (p<0.05, p<0.01, and p<0.001) dose related decreases in the weight gain pattern of treated rats effective from the 30th day to the 60th day of oral treatment when compared to the weight gain pattern of Vitamin C- and clomiphene-treated rats over the same treatment period. The most significant (p<0.001) weight reduction was observed at 400 mg/kg/day HU on the 60th day (Table 1). However, daily oral treatment with 0.3 mg/kg/day of clomiphene for 60 days caused steady and consistent body weight decreases of treated rats with the most significant (p<0.001) increase recorded on day 60 (Table 1). Similar effect was reported for 20 mg/kg/day of Vitamin C (Table 1).

3.3. Effect of Oral Treatment with 100-400 mg/kg/day of *Hunteria umbellata* Water Seed Extract on Rat Testicular Weight (TW) and Gonadosomatic Indices (GSI). Repeated oral treatment with 100, 200, and 400 mg/kg HU induced dose related increases in the testicular weight and GSI of treated rats with significant increases (p<0.001) recorded for the 400 mg/kg/day HU-treated rats (Table 2). The same effects were also recorded in clomiphene- and vitamin C-treated rats (Table 2).

3.4. Effect of Oral Treatment with 100-400 mg/kg/day of *Hunteria umbellata* Water Seed Extract on Rat Semen Parameters. Repeated daily oral treatment with 100 mg/kg/day, 200
mg/kg/day, and 400 mg/kg/day \textit{HU} for 60 days on semen analysis showed significant (p < 0.05, p < 0.01, and p < 0.001) dose-related increases in the total sperm count of treated rats with the most significant (p < 0.001) boost recorded in rats treated with the highest dose (400 mg/kg/day) of the extract which was comparable with what was recorded for the standard drug (0.3 mg/kg/day of clomiphene) (Table 3). Similar pattern was also recorded for % motile sperm counts (Table 3). However, \textit{HU} had a reverse effect on the \% dead sperm and \% abnormal sperm counts (Table 3) while 0.3 mg/kg/day of clomiphene caused a significant (p < 0.001) increase in the \% abnormal sperm count when compared to untreated control (Group I) rats (Table 3).

3.5. \textbf{Effect of Oral Treatment with 0.3 mg/kg/day of Clomiphene and 100-400 mg/kg/day of \textit{Hunteria umbellata} Water Seed Extract on Rat’s Sera TS, LH, FSH, PRL, and ES.} Repeated oral treatment with 0.3 mg/kg/day of clomiphene resulted in significant (p < 0.001) increases in the sera TS, LH, and FSH levels when compared to the untreated control (Group I) values (Table 4). However, 0.3 mg/kg/day clomiphene significantly (p < 0.05) reduced circulating serum ES level when compared to Group I values (Table 4). Similarly, repeated treatments with graded oral doses of \textit{HU} for 60 days resulted in significant (p < 0.05, p < 0.01, and p < 0.001) dose related increases in the circulating serum TS, LH, and FSH levels while resulting in significant (p < 0.05) reductions in serum PRL when compared to untreated control (Group I) values (Table 4). However, there were no significant alterations in the serum ES levels between the treatment groups and the untreated control group (Table 4).

3.6. \textbf{Effect of Oral Treatment with 0.3 mg/kg/day of Clomiphene and 100-400 mg/kg/day of \textit{Hunteria umbellata} Water Seed Extract on Rat Testicular Tissue SOD, CAT, and TBARS.} Repeated oral treatments with 0.3 mg/kg/day of clomiphene did not significantly (p > 0.05) alter the testicular tissue activities of SOD, CAT, and TBARS compared to those of untreated control (Group I) values (Table 5). However, repeated daily oral treatment with 100-400 mg/kg/day of

<sup>a,b</sup> and <sup>c</sup> represent significant increases at p<0.05, p<0.01, and p<0.001, respectively, when compared to Group I values, while <sup>d</sup> represents a significant decrease at p<0.05 when compared to Group I values.

I = 10 ml/kg/day of distilled water.
II = 0.3 mg/kg/day of clomiphene dissolved in distilled water.
III = 100 mg/kg/day of *Hunteria umbellata* aqueous seed extract dissolved in distilled water.
IV = 200 mg/kg/day of *Hunteria umbellata* aqueous seed extract dissolved in distilled water.
V = 400 mg/kg/day of *Hunteria umbellata* aqueous seed extract dissolved in distilled water.
VI = 20 mg/kg/day of Vitamin C dissolved in distilled water.

**HU** caused significant (p<0.05 and p<0.001) dose related increases in the testicular tissue levels of SOD, CAT, and TBARS when compared to both untreated control (Group I) and clomiphene-treated (Group II) values (Table 5). Similarly, oral treatments with 20 mg/kg/day of Vitamin C had similar effects on the testicular tissue SOD, CAT, and TBARS recorded for rats treated with 400 mg/kg/day of HU (Table 5).

3.7. Effect of Oral Treatment with 100–400 mg/kg/day of *Hunteria umbellata* Water Seed Extract on Rat Testicular Tissue GSH, GSH-Px, and GSR. Treatments with 100–400 mg/kg/day of HU caused significant (p<0.05, p<0.01, and p<0.001) dose related testicular tissue levels of GSH, GSH-Px, and GSR compared to untreated control (Group I) and clomiphene-treated (Group II) values (Table 6). However, the values obtained for 400 mg/kg/day of HU were comparable with those recorded for Vitamin C-treated rats (Table 6). It is also worthy to note that treatments with 0.3 mg/kg/day of clomiphene had no profound alterations (p>0.05) in the testicular tissue levels of GSH, GSH-Px, and GSR (Table 6).

4. Discussion

Infertility is the inability of a couple of opposite sex to achieve a clinical pregnancy after 52 weeks or more of regular unprotected sexual intercourse. In other words, it is a complete failure of a sexually competent and active, noncontracepting couple to achieve pregnancy in one or more years despite regular sexual exposures [25]. Recent epidemiological data has shown that approximately 15% of married/unnamed couples are affected by infertility for which only 40-50% cases are attributable to male infertility [26] which itself could be due to either azoospermia or erectile dysfunction [27]. Identifiable factors (reversible/irreversible) influencing male fertility as reported by previous studies include drugs (such as anabolic steroid, replacement testosterone, and opiates), testicular varicoceles, undescended testes, urinary tract infections, testicular tumor, hormonal imbalances, premature or retrograde ejaculation, prolonged heat exposure, obesity, older age, cigarette smoking, alcohol, heavy metals, pesticides, oxidative stress, genetic factors, and different environmental and nutritional factors [28–34]. Thus, in managing male infertility, treatment plans are designed alongside the

Identifiable possible cause and these interventions could be either medical or surgical [27, 35].

Apart from orthodox treatment of infertility, infertile couples are known to concomitantly use traditional/complementary medicine as therapeutic alternatives for their infertility since 25% of modern drugs are either plant-based or of plant origin [36]. More so, up to 80% of the world’s population is either partially or wholly dependent on herbal products for the treatment of their medical conditions [37]. However, in evaluating pharmacological activities of male fertility-enhancing medicinal plants, scientific investigations are done in vitro (using culture cell lines) and in vivo (using experimental animals and humans) models. For examples, extracts obtained from *Vanda tessellata* [38], *Turnera diffusa* and *Pfaffia paniculata* [39], *Eurycoma longifolia* [40], *Terminalia catappa* [41], *Butea frondosa* [42], *Curculigo orchioides* [43], *Panax quinquefolius* (ginseng) [44], and *Lepidium meyenii* have been investigated and reported to enhance aphrodisiacs while extracts obtained from *Astragalus membranaceus*, *Asparagus racemosus*, *Withania somnifera*, *Andrographis paniculata*, and *Acanthopanax senticosus* were also reported to improve sperm parameters [45, 46].

In this study we evaluated the possible fertility-enhancing and fertility mechanism of action of *HU* in male Wistar rats for 60 days as an alternative/complimentary to existing fertility-boosting drugs bearing in mind their high cost and untoward side effects associated with their clinical use. In doing this, male Wistar rats were gavaged with graded doses (100, 200, and 400 mg/kg/day) of *HU* in male Wistar rats for 60 consecutive days using endpoints such as the somato gonadal index, semen analysis parameters, and gonadal hormone profile as well as the testicular tissue antioxidant profile.

Hormonal analysis of *HU*-treated rats clearly showed the extract to significantly improve circulating sera TS, FSH, and LH while it decreased circulating prolactin. Literature has shown that serum elevation in the testosterone, FSH, and LH improves sperm quality in relation to sperm count, volume, motility, and morphology [43]. FSH and LH are known to influence the fate of germ cells and this influence is mediated via their actions on specific transmembrane receptors, Follicle Stimulating Hormone receptor (FSH-R), and Luteinizing Hormone receptor (LH-R) that are overtly expressed in the Sertoli cells and interstitial Leydig cells,
Evidence-Based Complementary and Alternative Medicine

repeated oral treatment with 100-400 mg/kg/day of HU significantly improved the antioxidant status of the treated rat testicles as indicated by increased levels of SOD, CAT, GSH, GSH-Px, GSR, and TBARS, which are in consonance with our previous in vitro [18] and in vivo [74] findings and that recently are reported by Oboh et al. [10]. Thus, these results clearly demonstrate the potential of HU in significantly improving the spermatogenic parameters via its antioxidant mechanism. Also, literature has shown antioxidants to improve various oxidative processes including spermatogenesis and steroidogenesis [68, 75], thus lending credence to the observed spermatogenic and steroidogenic effects of HU in the treated rats to be attributed to its high antioxidant profile.

5. Conclusion

Overall, prolonged oral treatments with 100-400 mg/kg/day of HU for 60 days significantly improved sperm function (as measured by sperm motility, count, viability, and morphology), mediated via increased spermatogenesis, steroidogenesis, and antioxidant mechanisms.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors have no conflicts of interest to declare. Adejuwon Adewale Adeneye is a Professor in the Department of Pharmacology, Therapeutics, and Toxicology, Faculty of Basic Clinical Sciences, Lagos State University College of Medicine, and the Principal Investigator of the present study. Joseph Abayomi Olagunju is a Professor in the Department of Medical Biochemistry, Faculty of Basic Medical Sciences, Lagos State University College of Medicine, and a Coinvestigator of this study. Babatunde Adekunle Murtala is Chief Technologist, Department of Physiology, Faculty of Basic Medical Sciences, Lagos State University College of Medicine, and a Coinvestigator of the present study.

Authors’ Contributions

Adejuwon Adewale Adeneye conceived, designed, and conducted the study. He also analyzed and interpreted the data and was responsible for the manuscript writing. Babatunde Adekunle Murtala conducted the semen analysis while Joseph Abayomi Olagunju also partook in the study design and data interpretation.
Acknowledgments

The authors thankfully acknowledge the full financial support given for this research work through the TETFUND Institution Based Research Fund, Second (2nd) Batch Research Project disbursement for the year 2016 cycle. Our research team also acknowledges the contributions of the Vice Chancellor and Management of Lagos State University (LASU) headed by Prof. Olanrewaju A. Fagbohun as well as the LASU TETFUND Desk Officer, Dr. Suraj Mudasiri, for facilitating and ensuring timely disbursement of fund for this research work. While the research team also duly acknowledges the technical support staff of the Animal House, LASUCOM, for the care of the Experimental Animal used during the period of the study, the technical support of Mr. Sunday O. Adenekan of BIOLIFE CONSULTS in the area of Oxidative Stress analysis is much appreciated. This research work is fully sponsored by the Federal Government of Nigeria through Tertiary Education Fund (TETFund) Institutional Based Research Grant.
