The human body is a remarkable biological machine maintained by interdependent body systems and organized biochemical reactions. Evolution has worked on humans for hundreds of thousands of years, yet the current pace of technological and social change have radically affected our life style and have exposed possible human frailties. This raises the question of whether or not nature's work could be improved upon. We provide two-sided perspectives as a rationale for the need for the redesign of the human body. Then, we describe pedagogical strategy through which students study morphological and anatomical structures and the physiological functions of the human body systems and their respective organs and parts. The students select their own favorite system or organ to redesign in order to optimize the efficiency of the anatomical structural, physiological function, and/or the aesthetic and functional morphology; a redesign that might lead to, for example, lowering risk of diabetes, heart attack, and/or stroke. Through group work and interaction (student groups compete for a prestigious "in-house" patent award), students actively engage in the learning process in order to understand the role of design in the efficiency and functionality and vulnerability to disease of the human body system.

1. Introduction

To keep us alive and living, the human body performs millions of complex functions throughout our lifetime. For example, in just 60 seconds, the human body takes 15 breaths, its heart beats 70 times, its tear ducts moisten the eyes 25 times, its brain conducts six million chemical reactions, its bone marrow produces 180 million blood cells, its skin sheds 10,000 particles of skin, and about 300 million of its cells die and/or are replaced [1, 2]. Furthermore, the human body manages to "extract the complex resources needed to survive, despite sharply varying

conditions, while at the same time, filtering out a multiplicity of toxins" [3, ¶ 5].

But as Nesse and Williams [5] inquired:

Why, in a body of such exquisite design, are there a thousand flaws and frailties that make us vulnerable to disease? If evolution by natural selection can shape sophisticated mechanisms such as the eye, heart, and brain, why hasn't it shaped ways to prevent nearsightedness, heart attacks, and Alzheimer's disease? If our immune system can recognize and attack a million foreign

proteins, why do we still get pneumonia? If a coil of DNA can reliably encode plans for an adult organism with ten trillion specialized cells, each in its proper place, why can't we grow a replacement for a damaged finger? If we can live a hundred years, why not two hundred? (p. 3)

Richard Dawkins [4] argues in his well-read book, *the greatest show on earth*, that animals appear to be elegantly designed, like following an engineer's blueprint. But when an animal is opened up on a dissecting table, it looks more like disorder than architectural design. As an instructive educational exercise, Dawkins proposes a redesign of the arteries leaving the heart: "I imagine the result would be something like the exhaust manifold of a car. . .instead of the haphazard mess that we actually see when we open a real chest" (p. 370-371).

Since much of what we think of as human capacity or intelligence derives from the way the body is constructed more than to the big size of our brains [10], in this pedagogical learning strategy students explore the human body by studying the morphological and anatomical structures, as well as the physiological functions of the human body systems and their organs and parts. They then select their own "favorite" body system, organ, and/or a part of the system to re-design in order to optimize the efficiency of the anatomical structure, physiological functions, and/or the aesthetic and functional morphology. Through group work and interaction, students actively engage in the learning process to (1) learn about the human body from the cellular level, to organ level, to whole system level, (2) understand the role of design in the efficiency and functionality of the human body system, (3) grasp and retain the new information, and (4) apply what has been learned in different situations.

2. The Human Body

The human body is a remarkable biological machine that is supported and maintained by well-structured and interdependent body systems and their unique organs, all contributing in different ways to the biological, physical, mental, and emotional health of a human being. It has about a hundred trillion cells, 60 miles of blood vessels, a 3-pound brain with 50 to 100 billion nerve cells and amazing thinking capacity, and 2.5 billion heart beats in a life time of 75 years, to name a few of its unique characteristics [2]. However, while thousands of years of evolution have adapted the human body to life on Earth, questions have been raised regarding whether or not the human body could be improved upon to meet, for example, the new challenges of the consequences of our current environment and lifestyles [11]. It is a fact that the human body is a marvel of complexity not only as a whole, but also at other levels of organization including body systems, organs, tissues, and cells. It is also a fact that the human body is "artistically beautiful and worthy of all the wonder and amazement it invokes" [12]. But as John Long [10] has indicated in his recent book, *Darwin's Devices*, evolution does not always make for better design.

For example, from an engineer's perspective, "it is a complex network of bones, muscles, tendons, valves and joints that are directly analogous to the fallible pulleys, pumps, levers and hinges in machines" [12]. Furthermore, it is also not perfectly efficient when it comes to function and energy saving mechanisms due to the internal designs of few parts, lack of functional purposes in some of its parts, and/or unsuitable locations of a number of its parts or redundancy of parts. For example, it is known that nearness to fuel supply is a fundamental principle in efficient industrial design, but yet, many important organs within the human body are located far away from the main source of fuel energy such as in the case of brain and the heart [13]. Another example is that if the resources (e.g., calcium) for building our teeth go to building fewer teeth, say 21 instead of 32, people *might* have less cavity problems and decayed teeth, due to infection caused by *Streptococcus mutant* bacterium [14]. The rest of the calcium could be used to support bones and reduce the bone fractures which are a serious problem for many older people. In addition, and as it is understood now, many human body parts have a limited power of regeneration, meaning they have a limited capability to replicate and/or repair themselves through cell division.

Throughout history humans have been praising the human body as nature's masterpiece and also suggesting a few improvements for various reasons and challenges. For example, more than 45 years ago, Lester David [13] surveyed a group of scientists, engineers, designers, and artists to see what they would suggest to improve the human body. He published his study in an article titled "*Science Redesigns the Human Body*" in 1956 in the *Modern Mechanix Illustrated Journal*. Citing George M. Rowland, Jr., one of the former presidents of Burdick-Rowland Associates, a nationally prominent firm of industrial designers at that time, David [13] wrote that

"From a designer's point of view, I see no reason for a disjointed spinal column. Why not encase the spine in a tube of semi-flexible cartilage? Thus man's spine would be a solid column, with a greatly increased load-carrying capacity. In addition, the vital nerves in the spine would be more fully protected against injury. Man would not be able to twist and turn as he does now but the semi-flexibility of the cylinder would allow enough bending for every ordinary purpose." [13, p. 53]

Mr. Rowland has also asked, "Couldn't the brain be situated in the chest cavity, near the heart instead in the head? There is another factor—if the brain was in the chest, it would be far less vulnerable to injury" [13, p. 53]. While this is an interesting idea, this is probably too far from our sensory organs to "work."

The re-design of the human body was also the subject of Ray Kurzweil's talk at the 2003 Time magazine's "The Future of Life" conference. In that talk and in an article with the same title, he discussed his vision of the Human Body Version 2.0. He explained that our bodies evolved in a very different era, under different environmental conditions. For example,

Our digestive processes in particular are optimized for a situation that is dramatically dissimilar to the one we find ourselves in. For most of our biological heritage, there was a high likelihood that the next foraging or hunting season (and for a brief, relatively recent period, the next planting season) might be catastrophically lean. So it made sense for our bodies to hold on to every possible calorie. Today, this biological strategy is extremely counterproductive. Our outdated metabolic programming underlies our contemporary epidemic of obesity and fuels pathological processes of degenerative disease such as coronary artery disease, and type II diabetes... As we're learning the principles of operation of the human body and the brain, we will soon be in a position to design vastly superior systems that will be more enjoyable, last longer, and perform better, without susceptibility to breakdown, disease, and aging. [3, Sections 6 and 9]

The human body was also the topic of a number of radio and television shows and programs such as the Science Channel, the National Geographic Channel, and the Discovery Channel, to name a few. For example, in 2008, the Science Channel reported the “top 10 useless body parts” by asking can there really be a useless organ? It even offered its viewers a survey to examine their own knowledge by asking them to name the ten most useless body parts. The Science Channel provided the following list of useless body parts: male nipples, appendix, wisdom teeth, arrector pili muscles, coccyx, tonsils, adenoids, sinuses, body hair, and *Plica semilunaris*. These in fact are evolutionary leftovers that are seen in many living species as signs of earlier lifestyles including physical features, internal processes, and aspects of behavior [15].

While the Science Channel may declare certain organs to be useless, it is important to note that “useless” does not necessarily mean the same thing as a vestige of evolution. A vestige is a trace of something that existed generations ago. Something can be of use and still a vestige, as long as the use is greatly diminished. For example, nipples on males are not a vestige since they did not appear on ancestors which had functional male nipples. On the other hand, human body hair, which is a vestige, is not useless because it is known to aid in the detection of ectoparasites. Thus, students must be made aware of where their information is coming from. They should know the difference between primary (original) and secondary sources of information, and that the Science Channel most likely provides secondary information through its programs.

But still this raises questions such as why are they still there if they do not have, as some believe, any more essential functions for the human body? Can we still survive without them being physically present as part of the human body? Since some evolutionary processes are slow and take time, are these parts already on their way out, and we just cannot recognize it? Why has the evolutionary processes not eliminated them by now or physiologically incorporated

them to benefit other parts of the human body? or, perhaps because we do not yet know their essential function, we should assume that they do not have one? (Although this assumption would be very uncharacteristic of scientific thinking.)

Redesigning the human body was also the subject of the BBC Radio 4 FM science program which was broadcast between January and July 2006. In eight audio episodes, Len Fisher wondered how the body would work if we had a go at remaking ourselves (see Appendix A). Len Fisher wondered about almost everything in and on the human body including the skin we are in and the guts we have. Fisher asked whether or not science can come up with anything better, such as a spare pair of arms, eyes in the back of our head, or superhearing, seeing, and touch. But how would the addition of “spare body parts” impact other organs and body systems, such as the brain?

Humans have been fascinated with the human body for many years and have pondered over the many ways it could be enhanced and redesigned. After all, as Nesse and Williams [5] argue in their book, *why we get sick*, in a body of such exquisite design, there are still a thousand flaws and frailties that make us vulnerable to disease and prevent us from easily living more than a hundred years. This leads us to ask the following question: if you could redesign the human body, what is the one change you would make? This is what makes “redesigning the human body” a worthwhile learning activity. It challenges students to answer a question that is both personal and relevant, allowing students to make connections between the subject matter and their own experiences, helping students to gain a deeper understanding of the human body. By making relevant connections, comparing varying perspectives, examining causality, and raising challenging questions, students are motivated to engage in the learning process. As Boyles and Contadino [16] argue, “an academic struggle begins when students do not have the hooks with which to connect the information given with their own experiences and strengths” (p. 35). However, in “redesigning the human body,” all students have the requisite prior knowledge of the human body (after all, they all possess a body and have experienced the benefits and challenges that come with them) and are able to connect with the information being learned.

It is also a worthwhile learning activity because it releases students’ thoughts and imagination. It allows them to *apply* what they learn about the human body and come up with well thought out designs and effective solutions to achieve potential optimum efficiency and functionality for their chosen system or organ. By applying their knowledge of the human body in a new situation, they engage in all of McCormack and Yager’s [9] learning domains, from knowledge acquisition to application and connection (see Appendix B).

3. Learning Activity

The objective of this learning activity is to help students understand the purpose of design, the relationship of design and function, and how altering the design of a given part,

organ, or body system could affect the efficiency of that particular part as well as the entire system and the whole living body. Biological design plays vital roles in the survival of the living body and the maintenance of homeostasis throughout the life of the individual (and possibly a role in the survival of the species). Furthermore, we want the students to realize that unlike human design, evolution, which is a gradual process of chemical and physical change, “never starts with an entirely blank drawing board, [but works instead] by modifying things that already exist” ([15], p. 10), thus evolution does not always make for better design [10]. This is simply because, as Dawkins [4] argues, evolution is a genetically controlled alteration in the development program of a given living thing.

A second objective is to actively engage students in group work and interaction not only to achieve a higher depth of understanding, but also to retain new information, and to apply what has been learned in a different situation, namely, the redesigning of their chosen human body system or organ. As Houghton [17] has argued, deep learning which promotes understanding and application for life involves linking new ideas to already known concepts and principles. This leads to a solid understanding and retention of learned concepts so that they can be used for problem solving in unfamiliar contexts or evaluating potential solutions to complex problems.

To begin, students are organized into groups and given the project to redesign a body part, organ, or body system with the goal of being awarded a patent for their design. Each team's design is judged by a team of “patent judges” who determine the winning design. Each group is asked to

- (i) select one of the 11 human body systems to research and study,
- (ii) identify and describe in writing the morphological and anatomical structure and the mechanical and physiological function of the given selected system and its main organs and parts,

The students should

- (i) include the description of specific function of the entire system as well as each organ and part within the system,
- (ii) identify the relationship within the structure,
- (iii) use, complete, and submit Table 1 as a summary fact-finding sheet,

Additionally, students are then asked to:

- (i) identify the part, organ, or whole body system to study and re-design,
- (ii) develop a convincing argument that their re-design is better and more efficient for achieving its main intended functional purpose. (Students use Tables 2 and 4 to help them organize their information of comparing and constructing the original design and the re-design of the selected body system, organ, and or part.)

After the initial presentation by the instructor, the students are given time (from 2-3 weeks) to work together and collect additional information necessary to develop a plan to redesign their selected part, organ, or body system. Subsequently, they implement their plan by creating detailed drawings and a written description of their re-design. The idea behind the redesign is to show how the redesign might lead to more desirable results. The members of each group must successfully argue to convince the class that their redesigned body system, organ, or part leads to a big improvement in the efficiency of that organ or part, and thus worthy of achieving a patent. (Patents are very prestigious and everyone wants a patent to make a name for themselves or their company.)

By engaging in research, studying the human body systems in detail, redesigning a given system, organ, or part and developing and presenting an informative and scientifically convincing argument for the efficiency of the redesign, the students learn to organize information, examine causality, compare varying perspectives, make choices, and improve social skills. Most of all, students reinforce their understanding of the composition and function of body systems and their organs and the interrelationships they play in the survival and health of the living individual. The finalized project is then presented to the class and to “patent judges.” Judges may be the class members or the instructor or visiting volunteer instructors.

By learning the reasons for the judges' choice, students gain insight into other individuals' thought processes. While the students may have effectively presented the importance of their re-design, the judges may have found another group's re-design more important due to the level of significantly enhanced functionality made by the re-design. After the judging, the class instructor needs to reinforce the “why” behind all the re-designs. The class instructor reinforces the idea of homeostasis and organ-system interrelationships, the need for continuous improvement, and the long-term biological mechanisms of how organisms respond to changes in their environment. Teachers should also emphasize the role of evolution and natural selection in the development of species.

4. Procedures

This learning activity can last two hours or two weeks, including preparation and presentation time. Both time frames work well.

4.1. Before Presentations

- (1) Form an evaluation committee which consists of the instructor of the class, another instructor from the school and one academically respected student from the same class (or have a “class vote/peer review” at the end of the presentations). The evaluation committee uses Table 5 to help them make its decision on which of the presentations should receive the very much coveted “Re-design Patent Award.”

TABLE 1: A summary of fact-finding sheet. Students could use it in the preparation for their re-design and presentation.

[illegible]

TABLE 3: Students' perspectives on the status of the human body's design.

The status of the human body design	Strongly disagree	Disagree	Neutral	Agree	Strongly agree
(1) Human body is perfectly designed; No need for improvement.					
(2) Human body is well designed; but can benefit from a few improvements.					
(3) Human body is functional with ok design, and can benefit from a few re-designs for improvement.					
(4) Human is functional, but not perfectly designed, and can benefit from the re-designed of many of its parts.					
(5) Human body needs total re-design to optimize its efficiency and functionality.					
(6) Wonderfully design doesn't necessary mean also wonderfully develop.					
(7) Wonderfully develop doesn't necessary mean also wonderfully made.					
(6) and (7) are modified from Dawkins [4].					

TABLE 4: Identified targeted areas for enhancement within the selected areas in given human body systems and or its organs.

Targeted area of enhancement	Underline proposed enhancement		
	Reasons	Mechanism	Predicted outcomes
(1) Physiological function			
(2) Neurological and communication function			
(3) Structural and supportive function			
(4) Morphological and aesthetic function			
(5) Anatomical function			

to the class. The evaluation committee/judge questions each group. The students in the class can ask up to three questions after a group completes its presentation. In addition, the members of each group take notice of all the questions that are asked.

- (2) After all groups finish presenting their cases, the members of the evaluation committee (judges) can ask more questions to all the groups. The students can also ask questions which the members of the evaluation committee must consider in their final judgment and decision for awarding the Re-design Patent Award to a given group.
- (3) The members of the evaluation committee wait until the next class meeting before sharing their final decision with the groups. During this time, and if there is room in the school, the posters, illustrations, and poems, and so forth) can be made available for all the students to view.

4.3. After the Presentation

- (1) In making their final decision, the members of the evaluation committee take into consideration the following.

- (a) The academic quality and integrity of the written paper, the oral presentation, the poster illustration, and/or any additional aids used by the students to help them convey their message, and demonstrate the importance of their re-design.
- (b) The use of the appropriate scientific concepts and principles in the re-designing of the selected part, and the accurate interpretation of scientific concepts, principles, and terminology. In addition, the use of the original design as a basis for the re-design (Tables 2 and 4).
- (c) The delivery of the presentations, the articulation of their arguments, the demonstration of the interrelationship between design, structure, and function, and the individual's personal involvement and engagement during the presentation and class discussion.
- (d) The type and quality of questions being asked during the process. In addition, the quality of the answers the groups provided to questions directed to them. (Teachers and instructors can see Cherif, et al. [19] for useful tools and techniques that can be used to monitor the level of cognitive involvement of the members of a

TABLE 5: Re-design patent awards and the reason behind they being awarded.

Patent award	Awarded for	Summary of reasons and rationale for the award
(1) Platinum

(5) Honorary mentioned		

given group during the activity as well as to record the type of questions being asked by the members of a group, the relevancy of the questions to the subject matter and to the point being debated, and to record the number of questions being asked by the members of one group to the other groups.)

- (2) Each group is given 2-3 minutes to address the committee one more time before the members of the evaluation committee read the final decision. In this short final remark, the groups must have a written statement that can be read to support their case of re-design and request for the Re-design Patent Award, based on a significant enhancement made in their redesign as well as academic accuracy in their proposal.
- (3) After all the groups present their final remarks, a representative of the evaluation committee reads and defends the committee's final decision. The members of the evaluation committee provide each group a copy of Table 5 which represents the committee's final decision.
- (4) The class Instructor must reinforce the concepts of design, patent (copyright), interrelationships of design, structure, and function, and the role homeostasis plays within a given body system in order to work effectively. (If, or when, the vermiform appendix is brought up the instructor can lead a very interesting discussion.) In an evolutionary sense, the instructor can comment that it once was extremely important and is now vestigial, but still it is not useless simply because something could be of use and still a vestige, as long as the use is greatly diminished.
- (2) Explain how your proposed re-design enhancement helps illuminate common occurrences of a given disorder and or disease.
- (3) Which organ (or organs) in an adult human body is able to regenerate naturally, to the extent that a living person can donate part of this organ to someone else, and within several weeks the two parts of this organ will regenerate into functioning, near-normal-sized organs?
- (4) Which organs in an adult human body are able to repair themselves after minor trauma?
- (5) Why is stem cell research important? What are the differences/similarities between embryonic and somatic stem cells? What is tissue grafting all about? Are these two techniques part of your re-design plan? Why or why not?
- (6) If you want your re-design to become reality and to appear generation after generation, at which level do you start your re-design: Molecular (DNA) level, embryonic development level, toddlerhood level, adulthood level? Explain.
- (7) Recently, it has been reported that Chinese researchers were able to regenerate skin from deep burns without the use of tissue grafting. What role can stem cell research and technology play in the regeneration of human body tissues, organs, and parts?
- (8) Capitalizing on the vast accumulation of this type of knowledge, biologists hope to make limb regeneration as well as other human body parts and/or organs a reality. Conduct library research and then discuss whether regeneration is better than re-design of your selected part, organ, or body system.
- (9) It has been known for centuries that simple animals such as worms and starfish can be easily cloned by cutting them in half. However, this method does not work for higher animals because of cell specialization. Conduct library research to find out how scientists overcome this obstacle in cloning higher animals.
- (10) While nothing can currently stop the process of aging, when it comes to the human life span, what percent of aging is accounted for by DNA and what percent is accounted for by behavior and lifestyle of a given individual? Explain.
- (11) Many researchers of aging prefer to use the term "healthy span" instead of "life span" and "active-life

5. Discussion Questions

The following questions can be used throughout this learning activity to generate discussion and engage students in critical thinking. Additional important discussion questions for promoting the development of deep thought and reflection among students on what they learned and understood from the activity can be seen in Appendix C.

- (1) Discuss the contribution of your selected body system to overall body systems as well as to each individual body system.

expectancy” instead of “life-expectancy.” Conduct library research and then explain the meaning of each term and the advantage of using one over the other.

(12) Ask your students to answer the following question

- (a) What type of body must you have in order to live to 100?
- (b) Give them 20 minutes to finish their assignment.
- (c) Discuss their answers in the class. Then share with them the following.

The body you want is short and squat, with stooped shoulders, backward-bending knees, pointy ears and hefty muscles. In other words, a gnomish creature that could rate a perfect 10 for mechanics and a total zero for glam. [This type of body might not bring you romance, but] at least, that's the vision of three of the nation's leading longevity researchers, who've come up with a blueprint for a human form that's built to last, if not forever, then certainly long past middle age, when the vagaries of gravity and nature start taking their toll on everything from perfect pecs to microscopic ear hairs. [26, Section 1].

6. Assessment

For assessing student's performance and understanding, as well as the effectiveness of these activities, we have been using McCormack and Yager's [9] taxonomy for science education as a framework for students' achievement. Appendix B contains a summary of McCormack and Yager's [9] taxonomy. It also contains some examples of assessment criteria that we have used in this activity. Notice that many assessment questions could fall into more than one domain depending upon how the questions are framed.

6.1. Related Activities to Reinforce and Expand upon the Learning Objectives. Additional activities can be designed and conducted to reinforce the understanding of the desirable learning objectives. Some possible examples include the following.

Homework Assignments (Optional). To reinforce the learning objectives of the activity, ask students to engage in the following homework assignments, either individually or in groups.

Homework Assignment 1. Ask students to answer the following questions (give them a time limit such as 10 minutes or the next class meeting).

- (1) Reflect on the final decision made by the members of the evaluation committee. Do you agree with it? Why or why not?
- (2) What have you learned from the activity at both academic and personal levels?

- (3) If you had to do this all over again, what would you change, discard, or add? Why?
- (4) On the Science Channel, a “top 10 useless body parts” was reported. Go to the web address below to read about them and conduct a library search to learn more about body parts such as these. Then complete Table 6. Make sure to critically complete all the columns, especially column 6 which requires you to justify your agreement or disagreement with the findings of the Science Channel on this specific topic. (<http://science.discovery.com/top-ten/2008/organs/organs.html>).

Homework Assignment 2. While there is always exception to the rule, animals that die naturally over a period of time can provide significant data on how long they are expected to live. This is called the average life span of a given organism. Conduct research to determine the maximum life span of 12 living organisms. Include in this list humans, lions, monkeys, eagles, turtles, lobsters, and alligators. Then use Table 7 below to answer the following questions.

- (1) list the maximum life span of each organism.
- (2) identify which of these 12 organisms:
 - (a) do and which do not suffer the indignities of aging,
 - (b) keep on growing throughout their lives,
 - (c) show no obvious loss of function as they get older.
- (3) is there a relationship between
 - (a) the size of the organism and its maximum life span?
 - (b) the type of the organism and its maximum life span?
 - (c) the environment in which a given organism lives and its maximum life span?

Homework Assignment 3. A disease is a condition in which the normal state (homeostatic regulations) of an organism is disturbed or impaired. It is usually characterized by specific diagnostic symptoms and signs that resulted from the distribution of the normal function of cells, tissues, organs, and/or systems by pathogenic organisms and thus, the body becomes incapable of performing normal functions. Conduct research to learn more about the human body and diseases and then answer the following questions:

- (1) choose an organ system.
- (2) list the organs and their common diseases. Then, answer the following questions:
 - (a) which organs are the most susceptible to disease? Explain.
 - (b) which organs are the least susceptible to disease? Explain.

TABLE 6: 10 useless body parts as reported by the science channel.

The human intestine contains trillions of microbes of at least 1,000 different species. Scientists are interested in learning more about how these organisms affect our lives and health. These types of studies have improved our understanding of the interactions between the normal gut flora and the immune system which led to the identification of the appendix as an apparent safe-house for normal gut bacteria. In a recent article, Bollinger et al. [6] proposed that “the human appendix is well suited as a “safe house” for communal bacteria, providing support for bacteria growth and potentially facilitating reinoculation of the colon in the event that contents of the intestinal tract are purged following exposure to a pathogen.” (p. 826). In additional, more and more recent articles add a much stronger refutation of the appendix as useless. Students are advised to look at, for example, the article written by Im et al. [7] in which the authors argue that the presence of an appendix might have a significant and independent function in helping to protect humans against *Clostridium difficile* recurrence (CDI) which causes gastrointestinal infection resulting in diarrhea and colitis. *Clostridium difficile* is a spore-forming anaerobic, and gram-positive bacterium that is raised in the human gut. Furthermore, another interesting study indicated that the cecal appendix may be viewed as a part of the immune system because is vital to life in a “natural” environment, but which is poorly suited to postindustrialized societies [8]. The conclusion is that teachers and instructors must emphasize the fact that something can be of use and still a vestige, as long as the use is greatly diminished.

(c) is there a relationship between the location of an organ in the human body and its susceptibility to a given disease? Explain.

(d) is there a relationship between the organ system into which a given organ belongs and its susceptibility to a given disease? Explain.

(3) list all the selected organs, their common functions, their common type of tissue, and whether or not they belong to more than one organ system.

(4) list all the organ systems, their estimated average weight, the estimated average human body weight, and the ratio of the organ weight to the whole body weight.

Final Remark. In this activity, we have created a learning environment and pedagogical opportunity for students to learn about the human body through redesigning some of its systems, organs, and/or parts with the aim to optimize body systems and efficiency without sacrificing functionality.

We hope that students develop an understanding that optimization could improve all system parameters in the human body, and also that the biological improvement of the human body through the re-design of some of its part is not only possible, but achievable and unavoidable. Additionally, we hope that we have created a learning activity through which students are challenged to learn new information about the human body, make strong connections with this information, and apply it in a new context, so that true understanding and long-term retention of knowledge is gained.

In their book, *Why we get Sick*, Nesse and Williams [5] argue that “despite their exquisite design, our bodies have crude flaws; despite our multiple defenses, we have a thousand vulnerabilities; and despite their capabilities for rapid and precise repairs, our bodies inevitably deteriorate and eventually fail” (p. 235). But as Gregory Stock [25] wrote in his article, *The Last Human*, “Never before have we had the power to manipulate human genetics to alter our biology in meaningful, predictable ways” (Section 4). Over the past hundred years, the field of biology has shifted from description to understanding to manipulation. In one century, “we have moved from observing to understanding to engineering” ([25], Section 24). And through this activity, we hope that we promote both active learning and STEM education among students.

See Table 9

C. Promoting Deep Thought and Reflection

Toward the end of the semester and after completion of all the activities related to the re-design of the human body, it is worthwhile for teachers and instructors to engage their students in a discussion that promotes the development of deep thought and reflection on what they learned and understood from the activity. The authors of this paper have found that the following questions, which have been suggested by one of the reviewers at the Education Research International, are very useful in achieving this goal. While all of these questions are educationally useful, we suggest that you select those questions that are related to the course you teach and the type of students you have.

- (1) Does the human still need to look and act human?
- (2) Are changes in I.Q. allowed, and are changes allowed which make the organism look nonhuman?
- (3) What about changes which alter tendencies toward aggression, fear, or other types of psychosocial-related issues?

- (4) Should scientists be allowed to make changes without addressing exactly how those changes are made?
- (5) Do we allow students to alter aging? If so, do they need to consider the impact on society?
- (6) Many people differ on what is a vestige or what is useless and what is not. “Useless” does not necessarily mean the same as a vestige of evolution. Explain the difference between both of them and provide examples of each.
- (7) Why do scientists always advise their students to go and investigate the original research rather than going to, for example, Science Channel and popular science news outlets?
- (8) There is controversy within the scientific literature regarding whether the appendix in humans has a useful function or is useless. You are a science journalist who is asked to put an end to this controversy by reporting on those who support and those who strongly refute that the appendix is a useless part of the human body.
- (9) You are a science journalist who is asked to investigate the phenomena of obesity in human society before and after the industrial revolution. Conduct investigative research to explain the difference in the trend of the increasing or decreasing rate of obesity and their root causes between these two distinct periods of human history.

D. Alternative Approach to the Learning Activity

Changing the time frame from a long project taking weeks or multiple class periods to one class period allows for a quicker “turn around” of information but does require some advanced study. Some of us have successfully conducted this activity with each organ system on a weekly basis to help students really understand the relationship between organs within each organ system. Students are given 20 minutes to form an argument and develop a short presentation, that is, supported with a poster, poem, and so forth. Then, each group of students is given 5 minutes to present their organ. This works extremely well for the digestive system’s organs (as stated by a number of students in one of the coauthor’s class). After all organs have been presented or “argued”/debated over, the class votes based on the presentations/persuasions. There is much to compare and contrast in this learning activity. This can have a lively impact on the class’s cohesiveness and can increase the “learning curves” of all students [27, 28]. The active participation “grabs” them. Continued references to a prior presentation/debate brings smiles and recollections to the students. Instructors can then build on that knowledge foundation and move on to the next organ system. Test scores were higher on topics that were covered in this manner as compared to the more traditional PowerPoint lecture topics presented by the instructor.

TABLE 8: BBC radio 4 FM redesigning the human body programs. Broadcasted between January–September 2006. Students can listen to them on digital radio, digital TV and online. <http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/9kmuc/>.

Title of the audio episode	Date of broadcasting	Len fisher's wonders	Len fisher's statements	Reference to the audio archive
(1) The Skin we're in	Monday 25 September 2006 9:30–9:45 (Radio 4 FM)	How the body would work if we had a go at remaking ourselves.	Len confronts his reflection and dreams about what he could do to make his skin more appealing.	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/9kmuc/
(2) Having the guts	Monday 18 September 2006 9:30–9:45 (Radio 4 FM)	Len Fisher wonders how the body would work if we had a go at remaking ourselves.	Indigestion, reflux, and excess gas—there are plenty of problems with our digestive system. Can science come up with anything better?	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/ozkjc/
(3) Moving along	Monday 11 September 2006 9:30–9:45 (Radio 4 FM)	Len Fisher wonders how the body would work if we had a go at remaking ourselves.	Getting around would be so much easier with wheels or springs. With the help of a physicist and a toymaker, Len gives rolling and hopping a try.	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/llo9a/
(4) A spare pair of arms...	Monday 4 September 2006 9:30–9:45 (Radio 4 FM)	Len Fisher wonders how the body would work if we had a go at remaking ourselves.	A spare pair of arms and eyes in the back of my head. Wouldn't it be great to have an extra limb or to see behind you? Len heads to the zoo to pick up some tips from the animal kingdom.	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/7s6ao/
(5) The skin we're in	Friday 6 January 2006 15:45–16:00 (Radio 4 FM)	Len Fisher wonders how the body would work if we had a go at remaking ourselves.	Sunburn, rashes, cuts, spots, chafing, wrinkles—our skin brings us no end of problems—vulnerable to damage, loosening as we age. What if instead of being rough and red or pale and pimply, our skin could be as vibrant as a bird's plumage or a lizard's scales? Contemplating his own skin in a theatre dressing room, Len is joined by consultant dermatologist David de Berker and biomimeticist Julian Vincent, to wonder what it would be like to shed our skin for something completely different.	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/sbrpt/

(6) Having the guts	Wednesday 4 January 2006 15:45–16:00 (Radio 4 FM)	Len Fisher wonders how the body would work if we had a go at remaking ourselves.	The human digestive system is a designer's nightmare, with indigestion, reflux, stomach aches, constipation, and involuntary leakage among its many problems. Len visits the University of the West of England, to meet a man who has designed a robot-Eco-bot, with a digestive system of its own.	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/lrgnp/
(7) Moving along	Tuesday 3 January 2006 15:45–16:00 (Radio 4 FM)	Len Fisher wonders how the body would work if we had a go at remaking ourselves.	Getting around would be so much easier with wheels or springs. With the help of a physicist and a toymaker, Len gives rolling and hopping a try.	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/oyy67/
(8) A spare pair of arms and eyes in the back of my head	Monday 2 January 2006 15:45–16:00 (Radio 4 FM)	Len Fisher wonders how the body would work if we had a go at remaking ourselves.	Wouldn't it be great to have an extra limb or to see behind you? Len heads to the zoo to pick up some tips from the animal kingdom.	http://www.bbc.co.uk/radio4/redesigninghumanbody/pip/s9xh0/

TABLE 9: McCormack and Yager's [9] taxonomy for science education as a framework for students' achievement, and how we have used it to assess student's performance and understanding in this activity.

Assessment domain	Description	Some suggested questions
(I) Knowledge domain	Students acquire knowledge of the subject, an understanding of relationships between the bodies of knowledge and give reasons for their approach to solving the problem.	<p>Did our students understand the form and function of the body systems including specific organs or parts well enough to complete this exercise? Based on organ diagrams or models were the students able to disprove or verify some of the supporting theories used in the discussion of various re-designs? What kinds of explanations did students offer for the relationships they observed and understood? Do they show a clear understanding of the anatomy? Do they show a clear understanding of the physiology? Can they explain the relationship between design, structure and function?</p> <p>In what form did creativity show itself in each group? Did each member of the group contribute? How did members of a given group of students compile data and information? Since this is not only a team effort of information collection but also a grade dependent project, creativity should be considered. For example, if muscles are being studied, consideration of the "extra" effort of going to a gym by the team or conducting video interviews of athletes should be taken into account. Was there cooperation in putting the information together? How efficient was each group in presenting and communicating the collected data and information? Were their delivery of statements and arguments smooth and coherent?</p>
(II) Process domain	Students learn how to collect, organize, and analyze data, develop strategies for building rational arguments and thoughts, state problems and generate valid conclusions, participate in team-work, and interpret meaning from the project.	

TABLE 9: Continued.

Assessment domain	Description	Some suggested questions
(III) Creative domain	Students apply imagination and creative thinking to the project, cultivate abilities to recognize, evaluate, use data and information provided by the other parts of the role play, and learn to modify a given design as needed.	This is often illustrated during the “Process Domain” stage as well. In what new ways did students use objects and ideas generated during the enactment of the learning activity to increase their understanding? The “judge” evaluates the importance of one re-design over another based on the creativity of the group members and the communication skills of the presenters. The vestigial vermiform appendix, because of a poem written and then read with such emotional force about its uses, was voted most important organ of digestion over all the other organs of digestion. How imaginative were students in identifying relevant problems, solutions, and conceptualizing new ideas? New twists are always tied with creativity. Challenging the students to deliver their information in another format (convincing presentation, poem, song,) may help them increase their communication skills as well as “bend” their knowledge of the subject matter and thus retain more of this self-gathered information.
(IV) Attitudinal domain	Students learn to listen closely and comprehend the other members of teams, group discussions, or parts of the role playing. They also learn cooperation in a group performance and self-evaluation.	This is a least a two-fold section: group to audience attitudes and also among members of the group itself (group dynamics). Were the group members able to effectively communicate their feelings of why their organ is important to the rest of the class and judges? How persuasives were group members in articulating their positions in order to change the attitudes of the others? Could they effectively defend the importance of one design over another? How smoothly did each group function? Did students’ sensitivity and respect for others develop during the process? How might the choice of the part to re-design or approach of presentation style reflect this sensitivity? Did members of the group demonstrate skills and abilities to resolve conflicts with others constructively? How might each group have functioned more effectively?

TABLE 9: Continued.

Assessment domain	Description	Some suggested questions
(V) Application and connection domain	Students learn to generate alternative approaches, problem-solving strategies, and solutions.	Did students come up with practical solutions/explanations? How well did the students integrate knowledge from different disciplines in their redesigns and applications? Was a consensus negotiated? Using the different aspects of science to explain a redesign shows a higher level of understanding of the subject. Physics and chemistry are the obvious companions to the anatomy and physiology. Math references may also be infused into the re-design's descriptions (use of pH scale within the stomach or blood). Ecology can be incorporated (define pollution as an excess of a chemical and then talk about how the stomach reacts with an excess of caffeine from 5 cups of coffee!). Referencing correctly is a required and honest attribute for all people. In this day and age of cut/paste from computers, it is extremely important and correct to give credit to the people who did the actual work. Are current references used? (It seems every two months there are "breakthroughs" in brain biology.) Bringing it "home" with a personal example is usually remembered by the other students and therefore aids in learning. To what extent did the students utilize their personal experiences and collective group understanding in making decisions related to the activity? Did the students construct viable solutions and compromises?

Acknowledgments

We would like to express our gratitude to the people who reviewed and provided constructive feedback for this manuscript: Dr. Maris Rose, Dr. Mathew Bruder, Dr. Gwo-Jen Hwang, Ms. Erica Solomon.
