The finite element boundary integral (FEM-BI) method is widely used in the scattering and radiating problems. But for the conducting body coated by thin-layer material, plenty of fine meshes are required to discretize the geometry in the traditional FEM. It requires very expensive storage and CPU time. In this paper, the hybrid shell vector element with the boundary integral method is used to expedite the solution of thin coating problems. The shell vector elements are used to discretize thin-layer material instead of traditional tetrahedral elements. Consequently, the volume integral can be simplified into surface integral. This method reduces the number of unknowns greatly and is also extended into the complicated case of multi-thin-layer coating materials. Several numerical results are presented to prove the accuracy and efficiency of this present method.

1. Introduction

The electromagnetic analysis of the conducting body coated by thin-layer material has received much attention because these composite dielectric and conductor structures are used in many applications, such as the evaluation of echo from stealth aircraft and microwave integrated circuits design. Plenty of research work has been done on the efficient solution of scattering from conducting body coated by thin-layer material.

For the analysis of conductor structures coated by thin-layer material, there are many methods available. Integral equation methods based on thin dielectric sheet approximation (TDS) [1–7] avoid the volumetric discretization of material region, the computational region is only limited as the surface of conductor. A multilevel-TDS extension is also proposed for solution of conducting body coated by multi-thin-layer materials [8–10]. For lossy thin-layer coating, the impedance boundary condition (IBC) is also developed to simplify the electromagnetic analysis by building the relation between the equivalent surface magnetic current and equivalent surface electric current on the surface of conductor [11]. The application of the IBC into the conducting bodies of revolution coated with thin magnetic materials is also developed successfully [12]. A rigorous moment method solution of composite bodies with thin features can achieve accurate results for thin coating problems if the near singularity for near-self term integral can be tackled carefully, as shown in [13, 14].

Besides the integral equation methods, the finite element method (FEM) is also widely used for analysis of composite conducting body and dielectric because of its powerful ability of modeling complex inhomogeneous materials [15]. As well known, the absorption boundary condition (ABC) is required in FEM in order to truncate the computational region. In order to combine together the advantage of FEM and integral equation, the hybrid FEM with the boundary integral method (FEM-BI) is proposed [15–23]. No ABC is needed in the FEM-BI, and the number of unknowns is reduced greatly.

Though FEM-BI has a good computational property for composite conducting body and dielectric, it is deficient for the analysis of conductor structures coated by thin-layer material. This is because plenty of fine meshes will be required for modeling thin layers if using traditional elements like tetrahedral elements. To further reduce the total number of unknowns, prism elements are used in FEM when solving
thin-coating structures [23]. In order to further enhance the computational efficiency, shell vector elements are developed in FEM, instead of prism elements [24, 25]. The volume integral can be simplified into surface integral by using shell vector elements.

In this paper, we combine the shell vector element method with the boundary integral method in order to achieve faster solution of scattering from conducting body coated by thin-layer material. The present method does not only reduce the number of unknowns but is also extended into more complicated cases of multi-thin-layer coating. This paper is organized as follows. The basic principle of the traditional FEM-BI method is reviewed in section II. Next, we show the characteristics of the shell elements, and the hybrid shell vector element method with the boundary integral method is implemented. Finally, several examples are shown to demonstrate the efficiency and accuracy of this present method. The conclusions are also given.

2. Traditional FEM-BI Method

Considering the electromagnetic scattering problem shown in Figure 1, the structure is illuminated by an incident plane wave \( E^{\text{inc}} \) or \( H^{\text{inc}} \), the \( \hat{n} \) is the unit normal vector on surface \( S \) and \( S \) is the surface enclosing volume \( V \).

The \( E \) field inside volume \( V \) satisfies the following equation:

\[
\nabla \times \left( \frac{1}{\mu_r} \nabla \times E \right) - k_0^2 \varepsilon_r E = 0,
\]

where \( \mu_r \) and \( \varepsilon_r \) denote the relative permeability and permittivity of the media, respectively, and \( k_0 \) is the wave number in free space.

The boundary conditions on surface \( S \) are written as

\[
\begin{align*}
\hat{n} \times E |_{S'} &= \hat{n} \times E |_{S}, \\
\hat{n} \times \left( \frac{1}{\mu_r} \nabla \times E \right) |_{S'} &= -j k_0 \hat{n} \times H_0 |_{S},
\end{align*}
\]

where \( H_0 = \eta_0 H \) and \( \eta_0 \) is the wave impedance in free space.

The FEM matrix can be constructed based on the variational method; the functional \( F(E) \) is expressed as follows:

\[
F(E) = \frac{1}{2} \int \int \int_V \left[ \frac{1}{\mu_r} (\nabla \times E) \cdot (\nabla \times E) - k_0^2 \varepsilon_r E \cdot E \right] dV \\
+ j k_0 \eta_0 \int \int_S \hat{n} \cdot (E \times H_s) dS.
\]

(3)

The tetrahedral element is most widely applied in traditional FEM and the electric field \( E \) can be expanded by the tetrahedral element as

\[
E = \sum_{j=1}^{6} E_j^s N_j^s,
\]

(4)

where \( E_j^s \) and \( N_j^s \) are the unknown coefficient and the basis function of the \( j \)th edge, respectively.

For the surface integral term in (3), the magnetic field on the surface can be expanded by three edges of planar triangle on surface \( S \) as

\[
H_s = \sum_{j=1}^{3} H_j^s N_j^s,
\]

(5)

where \( H_j^s \) and \( N_j^s \) are the unknown coefficient and the basis function of the \( j \)th edge, respectively.

Finally, the following FEM matrix equation is yielded from (3):

\[
[K] \{E\} + [B] \{H\} = \{0\}.
\]

(6)

In the FEM-BI method, surface integral equation method is applied on the surface \( S \). The electric field integral equation (EFIE) and the magnetic field integral equation (MFIE) are used as follows:

\[
E^{\text{inc}} = L(\overline{I}) - K(M),
\]

\[
H^{\text{inc}} = K(\overline{I}) + L(M).
\]

(7)

The equivalent surface electric and magnetic currents are defined as

\[
J = \hat{n} \times H, \\
M = E \times \hat{n}, \\
\overline{J} = \hat{n} \times \overline{H}.
\]

(8)

here \( \overline{H}^{\text{inc}} = \eta_0 H^{\text{inc}} \). The integral operators \( L \) and \( K \) are expressed, respectively, as

\[
L(X) = j k_0 \int_{S'} \left[ \frac{1}{r'} \nabla \nabla' \cdot X(r') \right] G(r, r') dS',
\]

\[
K(X) = \text{TY}(r) + \int_{S'} X(r') \times \nabla G(r, r') dS'.
\]

(9)

(10)

In (10), \( Y(r) = X(r) \times \hat{n}, \text{TY} = [1 - 1/4\pi (r-r')]e^{-jk_0|r-r'|/4\pi |r-r'|} \) is Green’s function.
in free space. The integral terms with bars in (10) denote the principal value integrals. The singularity is excluded.

By choosing $S_1^i = \hat{n} \times N_i$ as the weighting function, the TE formulation can be derived as

$$\begin{bmatrix} p_{TE} \end{bmatrix} \{E_5\} + \begin{bmatrix} Q_{TE} \end{bmatrix} \{H_5\} = \{ b_{TE} \},$$

where

$$p_{ij}^{TE} = -\int_S S_i^j \cdot K (N_j \times \hat{n}) \, ds,$$

$$Q_{ij}^{TE} = \int_S S_i^j \cdot L (\eta_0 \hat{n} \times N_j) \, ds,$$

$$b_i^{TE} = \int_S S_i^j \cdot E^i \, ds.$$

Similarly, the NE formulation can be derived by choosing $\hat{n} \times S_i^j$ as the weighting function as

$$\begin{bmatrix} p_{NE} \end{bmatrix} \{E_5\} + \begin{bmatrix} Q_{NE} \end{bmatrix} \{H_5\} = \{ b_{NE} \}.$$

The TH formulation can be derived by choosing $S_i^j$ as the weighting function as

$$\begin{bmatrix} p_{TH} \end{bmatrix} \{E_5\} + \begin{bmatrix} Q_{TH} \end{bmatrix} \{H_5\} = \{ b_{TH} \}.$$

The NH formulation can be derived by choosing $\hat{n} \times S_i^j$ as the weighting function as

$$\begin{bmatrix} p_{NH} \end{bmatrix} \{E_5\} + \begin{bmatrix} Q_{NH} \end{bmatrix} \{H_5\} = \{ b_{NH} \}.$$

To avoid the interior resonance that occurred in some cases, the combined field integral equation (CFIE), which combines the EFIE and MFIE, can be used,

$$\begin{bmatrix} P \end{bmatrix} \{E_5\} + \begin{bmatrix} Q \end{bmatrix} \{H_5\} = \{ b \},$$

where

$$P = \alpha \begin{bmatrix} p_{TE} \end{bmatrix} + \beta \begin{bmatrix} p_{NE} \end{bmatrix} + \gamma \begin{bmatrix} p_{NH} \end{bmatrix},$$

$$Q = \alpha \begin{bmatrix} Q_{TE} \end{bmatrix} + \beta \begin{bmatrix} Q_{NE} \end{bmatrix} + \gamma \begin{bmatrix} Q_{NH} \end{bmatrix},$$

$$b = \alpha \begin{bmatrix} b_{TE} \end{bmatrix} + \beta \begin{bmatrix} b_{NE} \end{bmatrix} + \gamma \begin{bmatrix} b_{NH} \end{bmatrix}.$$

The parameters $\alpha, \beta,$ and $\gamma$ satisfy: $\alpha + \beta + \gamma = 1$.

By combining (6) and (16), we get the matrix equation of the FEM-BI method as follows:

$$\begin{bmatrix} K_{ii} & K_{iS} & 0 \\ K_{Si} & K_{SS} & B \\ 0 & P & Q \end{bmatrix} \begin{bmatrix} E_i \\ E_S \\ H_S \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ b \end{bmatrix},$$

where $E_i$, $E_S$, and $H_S$ are the coefficient of the electric field inside volume $V$, on surface $S$, and the magnetic field on surface $S$, respectively.

### 3. Hybrid Shell Element with Boundary Integral (Hybrid Shell Element-BI)

The shell element is the degenerated prism element. As shown in Figure 2, there are six edge vectors along corresponding edges in the upper triangle and bottom triangle and three normal vectors. A linear function $\beta(x)$ was used to describe the variation of the field along the normal direction, and $\nabla \beta = -\hat{n} / d$. The $\beta N_j (j = 1, 2, 3)$ and $\beta' N'_j (j = 1, 2, 3)$ are the edge basis functions in the upper and bottom triangle, respectively. The $L_j, j = 1, 2, 3$ is the normal basis function at node $j$.

By the shell element, the electric field is expanded as follows:

$${E'} = \sum_{j=1}^{3} (E_j^i \beta N_j + E_j' \beta' N'_j) + \sum_{j=1}^{3} E_{nj} L_j^i \hat{n},$$

where $\beta' = 1 - \beta$, $N_j = (L_j^1 \nabla L_j^2 - L_j^2 \nabla L_j^1) \hat{n}$, $N'_j = (L_j^1 \nabla L'_j - L'_j \nabla L_j) \hat{n}$, $E_j^i$ is the expansion coefficient of the $j$th edge vector in the upper triangle, $E_j'$ is the expansion coefficient of the $j$th edge vector in the bottom triangle, $E_{nj}$ is the expansion coefficient of the normal vector at node $j$.

Based on (3) and (19), we attain

$$\int \int_B \int_v \nabla \times \left[ \beta N_j^i + \beta' N_j' + L_j^i \hat{n} \right] \cdot \nabla \times \left[ \sum_{j=1}^{3} (E_j^i \beta N_j^i + E_j' \beta' N_j') + \sum_{j=1}^{3} E_{nj} L_j^i \hat{n} \right]\, dV$$

$$- k_0 \epsilon_0 \sum_{j=1}^{3} \beta N_j^i + \beta' N_j' + L_j^i \hat{n} \right] \cdot \left[ \sum_{j=1}^{3} (E_j^i \beta N_j^i + E_j' \beta' N_j') + \sum_{j=1}^{3} E_{nj} L_j^i \hat{n} \right] \, dV$$

$= \int \int_S \hat{n} \cdot \left( \nabla \times N_j^i \right) \, ds.$

$$(20)$$

**Figure 2**: The structure of the prism element and the shell element.
For the shell element model, the volume integral can be simplified as:

\[
\int \int _{V} (\nabla \times \beta N_j^i) \cdot (\nabla \times \beta N_j^f) dv \\
= \int_{-1/2}^{1/2} \beta d\zeta \int_{s_j} (\nabla \times N_j^i) \cdot (\nabla \times N_j^f) ds \\
- \int_{-1/2}^{1/2} \beta d\zeta \int_{s_j} (\nabla \times N_j^i) \cdot S_j^d ds \\
- \int_{-1/2}^{1/2} \beta d\zeta \int_{s_j} S_j^d (\nabla \times N_j^f) ds + \frac{1}{2} \int_{-1/2}^{1/2} d\zeta \int_{s_j} S_j^f \cdot S_j^d ds,
\]

(21)

\[
\int \int _{V} (\nabla \times L_j^i \hat{n}) \cdot (\nabla \times \beta N_j^f) dv \\
= \int_{-1/2}^{1/2} \beta d\zeta \int_{s_j} (\nabla L_j^i \times \hat{n}) \cdot (\nabla \times N_j^f) ds \\
+ \int_{-1/2}^{1/2} \frac{1}{d} d\zeta \int_{s_j} (\nabla L_j^i \times \hat{n}) \cdot S_j^ds,
\]

where \( S_j^d = \hat{n} \times N_j^f, S_j^f = \hat{n} \times N_j^e \) and \( d \) is the thickness of the thin-layer material.

Obviously, the integration along the normal direction can be calculated analytically. So the volume integral can be simplified into the surface integral.

For the conducting object coated by thin-layer material, the electric field in the bottom surface of shell element must be zero, only the integral in the upper surface is needed.

The hybrid shell element-BI can also be extended into the conducting body coated by multi-thin-layered material. For example, for the conducting body coated by three-thin-layer material, the matrix equation is expressed as:

\[
\begin{bmatrix}
K_{m1} & K_{m2} & 0 \\
K_{n1} & K_{n2} & K_{n3} \\
K_{a1} & K_{a2} & K_{a3} \\
0 & 0 & B \\
P & Q & 0
\end{bmatrix}
\begin{bmatrix}
E_{n1} \\
E_{n2} \\
E_{n3} \\
E_{a1}
\end{bmatrix}
=
\begin{bmatrix}
0 \\
0 \\
0 \\
b
\end{bmatrix},
\]

(23)

where \( E_{n1} \) and \( E_{a1} \) are the expansion coefficients of the electric field in the normal and upper surface of the first layer, respectively; \( E_{n2} \) and \( E_{n3} \) are the expansion coefficients of the electric field in the normal and upper surface of the second layer, respectively; \( E_{n3} \) and \( E_{a3} \) are the expansion coefficients of the electric field in the normal and upper surface of the third layer, respectively.

4. Numerical Results

To demonstrate the accuracy and efficiency of the present method, some typical numerical results are shown here.

The first example is a conducting sphere coated by magnetic material, shown in Figure 3. The frequency is 300 MHz. The radius of the conducting sphere is 0.3367 m, and the thickness of the coating layer is 0.001 m. The relative permeability is \( \mu_r = 4 \) and the relative permittivity is \( \varepsilon_r = 1 \). In the hybrid shell element with BI, the mesh density of 15 elements per wavelength is enough for achieving reasonable accuracy, but in traditional FEM, at least 32 elements per wavelength are required in order to mesh this very thin layer successfully. Table 1 demonstrates the comparisons between the two methods. As shown in Figure 4, the results by the hybrid shell element with BI agree with the ones of MIE method very well. And, the number of the unknowns by the traditional FEM-BI and the present method is 15167 and 2249, respectively. Obviously, the advantage of the present method over the traditional FEM-BI in reducing the number of unknowns is very remarkable.

To further investigate the accuracy of the hybrid shell element-BI, Figure 6 shows the bistatic RCS of the conducting sphere coated by thin dielectric material, the geometry is shown in Figure 5, \( k_0 a = 6.28 \), the thickness of the thin layer is \( \delta/a = 0.1 \), and the relative permittivity is \( \varepsilon_r = 4 \), where \( k_0 \) is the wave number in free space and \( a \) is the radius of the conducting sphere. The mesh density used here is only

5. Conclusions

In this paper, the hybrid shell element with BI is developed to achieve efficient solution of scattering from the conducting body coated by thin-layer electric or magnetic material. Compared with the traditional FEM-BI, the present method reduces the number of unknowns greatly. Numerical results show that the hybrid shell element with BI is accurate and effective in solving the scattering problems of the conducting body coated with thin layer, also valid for the case of multi-thin-layer material coating.
