A dual-band design of monopole antenna with two coupled Y-shaped strips for WLAN/WiMAX applications is presented. By the introduction of dual Y-shaped strips, two separated impedance bandwidths of 22.4% (3.28–4.10 GHz) and 19.2% (4.90–5.94 GHz) can be obtained to meet the specifications of the WLAN/WiMAX communication band applications. The proposed antenna is successfully simulated, designed, and measured, demonstrating the matched impedance and good radiation characteristics with an overall dimension of 17.7 × 26 × 1 mm³.

1. Introduction

The rapid development of wireless communication urges the need of antennas covering multiple bands with good radiation characteristics. Thus, many researchers have been paying much attention to design this kind of antennas, such as in [1–9]. In [1], by the presence of an L-shaped parasitic strips, three resonant modes of the antenna for the 2.6/3.5/5.5 GHz-bands can be excited to meet the WiMAX system. By introducing dual U-shaped strips, multiresonant modes for WiMAX applications are proposed in [2]. In [3], with inclusion of an additional small radiation patch, a dual-band antenna designed from 3.1 to 10.6 GHz out of the band 5.0-6.0 GHz can be achieved. Two stacked T-shaped monopoles antenna was presented for 2.4/5.2 GHz WLAN-bands applications in [4]. A microstrip-fed dual U-shaped printed monopole antenna design for 2.4 and 5.8 GHz communication bands was introduced in [5]. A novel coplanar waveguide (CPW) antenna was proposed for dual-band WLAN applications in [6]. In [7], by etching an n-shaped slot on the radiating element, a novel coplanar waveguide- (CPW-) fed printed monopole antenna was proposed. In [8–10], other three different dual-band antennas were also presented by driven strip, modified half-bowtie radiating element, and variable frequency band-notch characteristic, respectively. Though new structures or designs have been given in above literatures, some shortcomings still exist to a certain extent. For the antennas in [1, 2, 4–6], the working bands cannot be separately adjusted flexibly. The structures in [3, 7] are designed for tunable notches, which may lead to inconstant impedance bandwidth of each operation band. Meanwhile, antennas in [8–10] have complex constructions which will somehow limit their low-cost terminal design in large-scale wireless communications. Besides, the overall dimensions of antenna are with large size, for example, 100 × 100 × 56 mm³ in [11], 32.5 × 20 × 1 mm³ in [12], and 30 × 26 × 1.6 mm³ in [13].

In this paper, a new design of dual-band monopole antenna with two coupled Y-shaped strips for WLAN/WiMAX applications is proposed. With the usage of two Y-shaped strips, both 5.2/5.8 GHz WLAN bands and 3.6/5.5 GHz WiMAX bands can be obtained. Specially, the presented antenna has the advantages of small size, simple structure, and steady gain. At the same time, both working bands can be separately adjusted by simple central angle of the up Y-shaped strip. The simulated and measured results show that the antenna can effectively cover two separated impedance bandwidths including 820 MHz (3.28–4.10 GHz)
2. Design and Analysis of Dual-Band Y-Shaped Antenna

Figure 1 illustrates the geometry and configuration of the proposed monopole antenna with two coupled Y-shaped strips for WLAN/WiMAX applications. A 50 Ω microstrip line is etched as the feeding structure on one side of the substrate with dielectric constant of 2.65 and a thickness of 1.65 mm. Good radiation characteristics of the antenna can also be obtained, which are verified by the simulated and measured results.

Figure 3 shows the simulated and measured return loss results of the proposed antenna. The proposed antenna has a low profile and can be easily fed by using a 50 Ω microstrip line with the overall dimension of 17.7 × 26 × 1 mm³. Good radiation characteristics of the antenna can also be obtained, which are verified by the simulated and measured results.

Figure 4 illustrates the current distributions on radiation patches. (a) The current distributions at 3.60 GHz and (b) the current distributions at 5.17 GHz.

The proposed antenna has two operating bands at 2.4 GHz and 5.2 GHz, and an omni-directional radiation pattern. The radiation patterns at these two bands are depicted in Figure 5. The realized gain at 2.4 GHz is about 5.5 dBi, and at 5.2 GHz it is about 6.0 dBi. The proposed antenna has a better directivity and gain compared to the conventional monopole antenna.

Figure 6 shows the simulated and measured radiation patterns in the xz-plane at 2.4 GHz and 5.2 GHz. The antenna has a good agreement between the simulated and measured results, which confirms the effectiveness of the proposed antenna design.
1 mm. On the other side of the dielectric substrate, a ground plane is printed below the microstrip feed line.

The practical fabricated dual Y-shaped monopole antenna is shown in Figure 2. The overall dimension of the antenna is $17.7 \times 26 \times 1$ mm$^3$. The simulated and the measured results are achieved by using the commercial simulation software HFSS and the Agilent E8357A vector network analyzer, respectively. The simulated and measured return loss results of the proposed dual-band antenna are shown in Figure 3, which have good agreement with each other. According to measured results, the antenna can effectively cover two separated impedance bandwidths of $820$ MHz ($3.28 \sim 4.10$ GHz) and $1040$ MHz ($4.90 \sim 5.94$ GHz), which can be well applied to $5.2/5.8$ GHz WLAN bands and $3.6/5.5$ GHz WiMAX bands.

In order to show the mechanism of the presented antenna, Figure 4 shows the surface current distributions of the proposed antenna at two different frequencies. When the antenna is working at near $3.60$ GHz, much surface current distributes at the up Y-shaped strip, which means that its resonance mode has been excited at $3.60$ GHz. We also know that much surface current distributes at both the up and down Y-shaped strips, which means that both of them provide the contribution for the resonance mode at $5.17$ GHz. What is more, the central frequency of the two bands can be approximately calculated by

$$f = \frac{c}{4\sqrt{\varepsilon_{\text{eff}}} \cdot L_{\text{total}}},$$

$$\varepsilon_{\text{eff}} = \frac{(\varepsilon_r + 1)}{2},$$

where $c$ is the speed of light, $\varepsilon_{\text{eff}}$ is the effective relative permittivity, $\varepsilon_r$ is the relative permittivity, and $L_{\text{total}}$ is the total length of Y-shaped strips. Clearly, the length of each strip is about a quarter of the guided wavelength $\lambda_g$. From Figure 5, it can be seen that the up Y-shaped strip provides the low resonance frequency at $3.56$ GHz, and the down Y-shaped strip resonates at $4.63$ GHz. By connecting with the two Y-shaped strips, the proposed antenna can cover two bands we desired. It means that the operation bands can be determined by both the two Y-shaped strips and the coupling of the two strips.

In order to analyze the affection of the central angle on the antenna’s return loss, Figures 6(a) and 6(b) show how
the return loss of the presented antenna changes with the central angle parameters of the two Y-shaped strips. From Figure 6(a), when the central angle of up Y-shaped strip is changed from 85.8 deg. to 90.8 deg., the low frequency band becomes distinctly lower and lower though the high working band has a slight shift, resulting from small couplings of two Y-shaped strips for the resonance mode at 5.17 GHz, shown in Figure 4(b). On the other hand, from Figure 6(b), we also know that the higher frequency band can be obviously adapted as the central angle of down Y-shaped strip is changed, in the case of keeping the lower working band nearly unchanged, which can be explained by the current distributions in Figure 4(a). In a word, the two bands of present dual-band antenna can be basically independently controlled by main physical parameters.

In Figure 7, the simulated and measured normalized radiation patterns for the antenna are shown. The antenna’s E-plane (x-z plane) and H-plane (x-y plane) radiation pattern at 3.60 GHz is shown in Figure 7(a). The E-plane and H-plane radiation patterns at 5.17 GHz are shown in Figure 7(b). It can be observed that the simulated results and measured results are in good agreement and good omnidirectional patterns are obtained for the two frequency bands in x-y plane, and close to bidirectional patterns in x-z planes are achieved. Figure 8 illustrates the simulated and measured peak gains of the proposed antenna. According the measured results, their peak gains are about 3.51 dBi, 3.77 dBi, 3.58 dBi, and 3.41 dBi at 3.6 GHz, 5.2 GHz, 5.5 GHz, and 5.8 GHz, respectively. The present monopole antenna provides good radiation characteristics at the two working frequency bands from what is mentioned above.

3. Conclusion

In this research, a dual-band design of monopole antenna with two coupled Y-shaped strips for WLAN/WiMAX applications is presented and implemented. By introducing the dual Y-shaped strips, two separated bands can be effectively achieved, which is verified by simulated and measured results. The antenna also gives good radiation characteristics at the two desired working frequency bands.
