1. Introduction

Anaplastic thyroid cancer (ATC) is among the most lethal types of cancers, characterized as a fast-growing and highly invasive thyroid tumor that is unresponsive to surgery and radioiodine, blunting therapeutic efficacy. Classically, genetic alterations in tumor suppressor $TP53$ are frequent, and cumulative alterations in different signaling pathways, such as MAPK and PI3K, are detected in ATC. Recently, deregulation in microRNAs (miRNAs), a class of small endogenous RNAs that regulate protein expression, has been implicated in tumorigenesis and cancer progression. Deregulation of miRNA expression is detected in thyroid cancer. Upregulation of miRNAs, such as $\text{miR-146b}$, $\text{miR-221}$, and $\text{miR-222}$, is observed in ATC and also in differentiated thyroid cancer (papillary and follicular), indicating that these miRNAs’ overexpression is essential in maintaining tumorigenesis. However, specific miRNAs are downregulated in ATC, such as those of the $\text{miR-200}$ and $\text{miR-30}$ families, which are important negative regulators of cell migration, invasion, and epithelial-to-mesenchymal transition (EMT), processes that are overactivated in ATC. Therefore, molecular interference to restore the expression of tumor suppressor miRNAs, or to blunt overexpressed oncogenic miRNAs, is a promising therapeutic approach to ameliorate the treatment of ATC. In this review, we will explore the importance of miRNA deregulation for ATC cell biology.
restricted to the thyroid gland (Tg-BRAF) that is affected by high penetrance PTC that undergoes temporal dedifferentiation [13]. Molecular analysis of Tg-BRAF mice-derived tumors reveals the deregulation of TGFβ signaling upon prolonged stimulation of the BRAF oncogene, with enhanced TGFβ signaling transduction and a shift to EMT by ZEB1 and ZEB2 transcription factor activation [14]. Another transgenic model with BRAF activation in adult mice also gives rise to differentiated thyroid cancer; however, progression to ATC requires TP53 gene deletion [15], corroborating the multistep cancer progression hypothesis for ATC. A mouse model harboring defective PI3K signaling gives rise to aggressive thyroid cancer. Transgenic mice carrying deletions of Pten and TP53 [Pten, p53][thyr-/-] develop ATC with loss of expression of the thyroid transcription factors, Nkx2-1, Pax-8, and Foxe1, and thyroid differentiation markers, Nis, Tpo, Tg, Tshr, and Duox [16]. [Pten, p53][thyr-/-] mice thyroid tumors undergo TGFβ signaling induced EMT and demonstrate increased pSMAD2 and vimentin levels, but loss of E-cadherin expression.

Recently, a pivotal role for microRNAs (miRNAs) in cancer has emerged with increasing evidence showing that they may drive and potentiate oncogenesis. The miRNAs are a class of small noncoding RNAs (~20 nt) that regulates post-transcriptional gene expression. These miRNAs are transcribed as long primary RNAs that undergo sequential cleavages by Drosha and Dicer ribonucleases in the nucleus and cytoplasm, respectively, to yield mature miRNA. In turn, mature miRNA associates with the protein complex RISC (RNA-induced silencing complex), which directs pairing with the 3′-UTR region of target mRNAs. Imperfect pairing leads to translational blockage of target mRNA and, also, mRNA deadenylation and decay (Figure 1).

Essentially, miRNA deregulation in cancer is oncogenic (oncomiR) under two different conditions: (a) when overexpressed, miRNAs may block tumor suppressor gene translation or (b) when underexpressed, miRNAs may derepress protooncogene mRNA translation (Figure 2).

Deregulation of miRNA in thyroid cancer was initially described by He et al. in a group of PTCs [17]. The same group of upregulated miRNAs, such as miR-146b, miR-221, and miR-222, is commonly detected in ATC and in differentiated thyroid cancers (papillary and follicular histotypes) [18] and also in a fraction of benign nodules [17, 19], indicating that persistent expression of these miRNAs may be necessary to maintain tumorigenesis. However, ATC also shows exclusive reduction of certain miRNAs with tumor suppressor properties, indicating a role for these miRNAs in tumor aggressiveness (Figure 3). Investigating tumour samples from a group of ten ATC patients by microarray analysis, the seminal study of Visone et al. [20] revealed the repression of miR-30d, miR-125b, miR-26a, and miR-30a-5p. In addition, another study showed a reduction of several members of the let-7 and miR-200 family of miRNAs [21] and overexpression of miR-221, miR-222, and miR-125a-3p.

In this review, we will explore some aspects of the deregulated miRNA found in anaplastic thyroid cancer to address the molecular biology and signaling pathways implicated in the clinical-pathological characteristics of this type of cancer (Table 1).

**Figure 2:** Some miRNAs act as oncomiRs. Deregulation of miRNA changes physiological protein level balances and enhances the oncogenic process where (1) low expression of an miRNA may enhance protein translation of an oncogenic protein or (2) high expression of an miRNA may repress the translation of a tumor suppressor gene. Both situations may occur concomitantly in cancer as observed in anaplastic thyroid cancer.

#### 2. Downregulated miRNAs in ATC

Specific miRNAs are reduced in thyroid cancer, such as the *let-7* family, but other miRNAs, such as the *miR-200* and *miR-30* families, are exclusively downregulated in ATC, indicating that the latter miRNAs may play a role in the acquisition of more aggressive tumor characteristics (i.e., enhanced cell invasion and migration).

##### 2.1. miR-200 Family

The *miR-200* family is composed of the *miR-200a, miR-200b*, and *miR-200c* genes, which are usually downregulated in ATC [21]. The *miR-200a* and *miR-200b*
genes make up a cluster located on chromosome 1, while the miR-200c gene is located on chromosome 12. An important transcriptional activator of miR-200 is p53, which binds to the promoter region of miR-200c at multiple sites. Interestingly, a TP53 mutation at a DNA binding domain as present in ATC impairs downstream transcriptional activation of miR-200 [22]. Moreover, p53 is an important controller of tumor suppressor miRNAs, such as those of the miR-34 family, and also influences miRNA processing [23], besides having a classical role in DNA repair and genomic stability. Another signaling pathway that influences miR-200 expression is the EGF pathway. Overexpression of the EGF receptor, EGFR, is observed in ATC [24], while EGFR knockdown in ATC cells restores miR-200 expression and represses the expression of mesenchymal markers [25]. Classically, TGFβ signaling induces epithelial-to-mesenchymal transition (EMT), via the transcriptional activation of ZEB1 and ZEB2 [21], inducing a mesenchymal phenotype, with the expression of vimentin and repression of E-cadherin as observed in ATC. Interestingly, the miR-200 family is an important regulator of the EMT process by regulating ZEB1 and ZEB2 protein levels. Downregulation of miR-200 in ATC would potentiate the TGFβ-mediated EMT switch and enhance aggressiveness.

2.2. miR-30 Family. The miR-30 family of tumor suppressor miRNAs is composed of five members: miR-30a, miR-30b, miR-30c, miR-30d, and miR-30e. Downregulation of the miR-30 family is observed in several types of cancer such as breast, bladder, and colon [26,27]. Moreover, decreased expression of miR-30 is observed in metastasis compared to the primary tumor [28], suggesting a role in aggressive disease. In ATC, miR-30 expression is also reduced in tumor samples [20,29]. Indeed, modulation of miR-30 levels in ATC cells has a great impact in cancer cell biology. Importantly, miR-30d ectopic expression in an ATC cell line reduced monolayer cell growth and impaired anchorage-independent cell growth [30].

Downregulation of miR-30 derepresses the expression of EZH2, an important component of the polycomb repressive complex 2 (PRC2) that regulates chromatin condensation and gene expression. EZH2 is the enzymatic subunit of histone methyltransferase that trimethylates histone H3 lysine 27. EZH2 is overexpressed in ATC and enhances cell proliferation, migration, and invasion, while repressing the expression of thyroid transcription factor PAX8 [31]. Another important cellular process regulated by the miR-30 family is autophagy through targeting the key autophagy-promoting protein, Beclin1 (gene BECN1). In ATC, miR-30d restoration sensitizes cancer cells to cisplatin treatment by repressing Beclin1, which participates in the early stages of autophagosome formation [32]. An miR-30d mimetic enhanced the apoptotic effects of cisplatin as shown by increased cleaved caspase-3 and PARP levels and annexin V staining [33]. Moreover, cisplatin treatment in a xenograft model also showed shrinkage of ATC tumor derived from miR-30 overexpressing cells. The blockage of autophagy using specific inhibitors exerts similar effects to the reintroduction of miR-30 into ATC cells, indicating that the autophagy process is important for ATC cells' resistance to chemotherapy.

2.3. let-7 Family. Family genes of let-7 are located on different chromosomes and are abundantly expressed in a normal thyroid gland (let-7a, let-7b, let-7c, let-7d, let-7e, let-7f, and let-7g) [34]. Deregulation of let-7 is observed in several types of cancer, and its tumor suppressor effects are usually abolished by its downregulation [35]. let-7 was the first miRNA identified as having a role in cancer through validation of RAS protooncogene mRNA targeting and the association of low levels of let-7 with a poor prognosis in lung cancer [36]. Downregulation of several members of the let-7 family is observed in well-differentiated thyroid cancer (PTC and FTC) [37–39], but a marked decrease in the expression of let-7a, let-7c, let-7d, let-7f, let-7g, and let-7i is also observed in ATC [20,21,29].

Modulation of let-7 levels alters thyroid cancer cell biology. Ectopic expression of let-7f in a PTC cell line inhibits cell proliferation and viability, while it reduces the activation of MAPK signaling, an important marker of thyroid cancer [40]. Moreover, let-7 enhances the expression of thyroid transcription factor-1 (TTF1/NKX2-1), a key factor in maintaining the expression of iodine metabolizing genes and thyroid
differentiation, usually lost in ATC. The recovery of Let-7a expression in an FTC cell line changes cell morphology to an epithelial-like phenotype (flat and adherent), while it reduces cell migration by targeting FXYD5, an important regulator of cell adhesion [39]. Moreover, in aggressive lung cancer, loss of Let-7 is associated with a poorer prognosis [36], and the reduction of Let-7c is associated with refractoriness to chemotherapeutic treatments. Indeed, the ectopic expression of Let-7c in a lung cancer cell line restores the cells’ response to chemotherapeutic regimens and represses the EMT process [41], indicating an important role for Let-7 in tumor aggressiveness.

3. Upregulated miRNAs in ATC

Common miRNAs such as miR-146, miR-221, miR-222, and miR-17-92 are upregulated in aggressive ATC and in well-differentiated thyroid cancer, indicating that reinforced expression of these miRNAs is important in maintaining the oncogenic process.

3.1. Cluster miR-17-92. The miR-17-92 cluster is located on chromosome 13 and transcribes a polycistron that yields seven different mature miRNAs: miR-17-5p, miR-17-3p, miR-18a, miR-19a, miR-19b, miR-20a, and miR-92a. In normal thyroid follicular cells, early BRAFV600E oncogene activation induces the expression of an miR-17-92 cluster [42]. The BRAF oncogene is the most frequent genetic alteration in thyroid cancer (i.e., FTC) and is also detected in ATC, associated with poor clinical-pathological features of cancer such as extrathyroidal invasion, short time recurrence, and distant metastases [43, 44]. High levels of miR-17-92 components are expressed in ATC [45], similar to that observed in other types of cancer, such as lung, colon, pancreatic, and lymphoma [46], especially in the aggressive forms of disease [47].

The molecular modulation of endogenous levels of these miRNAs using LNA (locked nucleic acid) modification resulted in important effects in ATC cell biology. Specific blockage of miR-17-5p, miR-17-3p, and miR-19a resulted in a pronounced growth inhibition of ATC cells and apoptosis through activation of caspase-3 and caspase-9 [45]. Inhibition of the miR-17-92 cluster in ATC leads to the recovery of PTEN protein levels [45], an important negative regulator of PI3K growth signaling, which is repressed in ATC. Moreover, among several validated targets for the miR-17-92 cluster are proteins associated with tumor aggressiveness. A key target that influences tumor invasion is TIMP-3, an important inhibitor of metalloproteinase activation, targeted by miR-17-5p and miR-17-3p.

3.2. miR-146a and miR-146b. The miR-146 family, miR-146a and miR-146b, is overexpressed in ATC [18, 29, 48]. Despite sharing the same seed region, and therefore targets, miR-146a and miR-146b are transcribed by two independent genes located on chromosomes 5 and 10, respectively, and regulated by the transcription factor NFκB. The promoter region of both miRNAs contains binding sites for the NFκB complex, part of a key oncogenic signaling pathway, usually overactivated in ATC, which shows increased nuclear staining for RelA (p65), the subunit of the NFκB dimer [49]. Ectopic expression of the inhibitory protein of this signaling, IκB, decreases miR-146a and miR-146b levels in an ATC cell line [48]. Moreover, inhibition of miR-146a leads to an abrogation of anchorage-independent growth and invasion by ATC cells [48]. Interestingly, NFκB activation is observed at the invasive front of aggressive PTC showing local invasion compared to the central region of the tumor [50] and also in response to a BRAFV600E oncogene, leading to cell migration and invasion [51], and miR-146b upregulation [52]. Moreover, the introduction of miR-146b into PTC mutated cells (BRAFV600E or RET/PTC1) enhances cell invasiveness and migration [53]. Therefore, the NFκB signaling pathway and its transcriptionally activated miRNAs, miR-146a and miR-146b, play an important role in thyroid cancer aggressiveness and progression. Indeed, increased plasma circulating levels of miR-146b can be detected in papillary thyroid cancer before surgery, which also correlates with tumor aggressiveness and poor prognosis [54].

3.3. miR-221 and miR-222. miR-221/miR-222 is a cluster of miRNAs, located on chromosome X, which is deregulated in thyroid cancer. Although miR-221 and miR-222 overexpression is detected in differentiated (PTC and FTC) [17, 37] and anaplastic thyroid cancer cells [18, 29, 55], the expression of these miRNAs is associated with poor clinical-pathological features of cancer. In PTC and FTC, levels of miR-221 and miR-222 positively correlate with tumor aggressiveness, increased extrathyroidal invasion, tumor size, higher tumor node metastasis stage, and papillary thyroid cancer recurrence [18, 56–58]. Indeed, higher expression of miR-221 and miR-222 is present in metastatic, in comparison to nonmetastatic, cancers [59]. Moreover, miR-222 increased circulating plasma level is associated with the presence of the BRAF mutation and recurrent papillary thyroid cancer [54].

Ectopic expression of miR-221 in cancer cells results in a robust increase in anchorage-independent growth in soft-agar medium [37], pointing to a role for this cluster of miRNAs in the process of invasion and cell migration. Indeed, one target of the cluster is RECK, an inhibitor of metalloproteinase activity. Inhibition of miR-221 impairs cell migration and invasion via upregulation of RECK while it reduces metastases in a colon cancer mouse model [60]. Both miR-221 and miR-222 also influence cell proliferation, once overexpression deregulates the cell cycle, by targeting the p27kpc (CDKN1B) protein, a key regulator of cell cycle progression [61].

4. Concluding Remarks

Currently, there is no effective therapy to blunt the lethal course of ATC, therefore prompting trials of additional and innovative therapies for ATC. Molecular targeted therapy for ATC seems to be a promising approach to retard cancer growth and increase patient survival. The molecular modulation of miRNA levels using miRNA mimics or anti-miRs, allied to a novel class of highly specific inhibitors of MAPK and PI3K signaling, for instance, may enhance the ATC response to conventional treatment [62].
Systemic miRNA injection has showed promising results using lipid and other carrier molecules for treating lung and prostate cancer in animal models. Intratumoral injection or tail vein injection of a lipid-based miR-34a inhibited orthotopic prostate cancer tumor growth and metastases in immune-deficient mice [63], and lentivirus mediated miR-34a delivery to prostate cancer cells completely inhibited tumor growth. Moreover, the growth of prostate cancer bone metastases was significantly inhibited by systemically injecting miR-16 complexed with atelocollagen [64]. In lung cancer, systemic injection of a neutral lipid emulsion of miR-34a and let-7 significantly decreased in tumor burden in a mouse model of non-small cell lung cancer (NSCLC) [65]. Interestingly, a promising drug called miravirsen (SPC3649) is under phase II clinical trial for treating hepatic cancer. Miravirsen is a 15-nucleotide locked nucleic acid-modified antisense oligonucleotide with high affinity and specificity to miR-122, an miRNA used by HCV for hepatic cells infection [66].

Further studies in vitro and in animal models concerning the functional role of miRNAs and the impact of modulating oncomiR endogenous levels in ATC are one key to their future application as therapeutic adjuvant treatments. In particular, ATC patients would benefit from the concomitant reintroduction of tumor suppressor miRNAs miR-200 and miR-30 and the inhibition of the oncogenic miR-146, miR-221/miR-222, and miR-17-92 clusters, as these miRNAs target several deregulated processes such as cell growth, invasion, migration, and EMT.
