ABSTRACT. For positive operators on a Banach lattice, absolute continuity conditions are considered. An operator absolutely continuous with respect to $T$ is compared to sums of compositions of $T$ together with orthomorphisms or in special cases projections. Consequences for compact operators on functions spaces $C(X)$ are considered.

KEY WORDS AND PHRASES. Banach lattices, orthomorphisms, quasi-interior points.

1980 AMS SUBJECT CLASSIFICATION CODES. 46B30, 47B05, 47B55.

1. INTRODUCTION

For positive operators $S$ and $T$ between real Banach lattices several types of "absolute continuity" have been defined. Here, we consider an absolute continuity which will be applicable to spaces which are not necessarily Dedekind complete. Several approximations of an operator absolutely continuous with respect to $T$ are provided in terms of sums of operators of the form $Q_i T Q_i H_i$, where $Q_i$ and $H_i$ are orthomorphisms. These approximations are compared to results known for operators $S$ less than $T$ and for operators on Dedekind complete Banach lattices. We also examine the relationship between this and previous notions of absolute continuity. We begin by recalling the following definitions.

DEFINITION. (Luxemburg [1]). Let $E$, $F$ be Riesz spaces with $S$, $T$ positive operators from $E$ to $F$. We say that $S$ is absolutely continuous with respect to $T$ if for each positive element $f$ in $E$, we have that $Sf$ is in the band generated by $Tf$. 
DEFINITION. (Feldman [2]). Let \( E, F \) be Banach lattices with \( S, T \) positive operators from \( E \) to \( F \). We say that \( S \) is \( t \)-absolutely continuous with respect to \( T \) if for each positive element \( f \) in \( E \), we have that \( Sf \) is in the closure of the order ideal generated by \( Tf \).

We note that for linear functionals on \( E = C(X) \) (the continuous real-valued functions on a compact topological space \( X \)) when \( E \) is Dedekind complete, these two notions are equivalent to the usual definition of absolute continuity. The absolute continuity introduced here will be shown to be equivalent to the usual notion for functionals on any \( C(X) \).

In what follows we will refer to a decreasing sequence \( \{f_k\} \) of positive elements of a Banach lattice \( E \) as a \textit{positive decreasing sequence in} \( E \). We now introduce our version of absolute continuity.

DEFINITION. Let \( E, F \) be Banach Lattices and let \( S, T \) be positive operators from \( E \) to \( F \). We say that \( S \) is sequentially absolutely continuous (s-absolutely continuous) with respect to \( T \) if for each positive decreasing sequence \( \{f_k\} \) in \( E \) and each positive linear functional \( \phi \) on \( F \), we have that \( \lim(\phi(Tf_k)) = 0 \) implies \( \lim(\phi(Sf_k)) = 0 \).

We will be concerned with Banach lattices with quasi-interior points. An element \( e \) of a Banach lattice \( E \) is a quasi-interior point if the order ideal generated by \( e \) is dense in \( E \). Recall that the order ideal generated by \( e \) is the set of all elements whose absolute value is bounded by some multiple of \( e \). If \( E \) is equal to the order ideal generated by an element \( e \) then \( e \) is an order unit. Recall that if \( E \) is a Banach lattice with quasi-interior point, the elements of \( E \) can be represented as extended real valued functions on a compact set \( X \) each finite on a dense subset (see [3]). We shall call \( X \) a representation space for \( E \). Further, this representation contains \( C(X) \) as a dense order ideal. If \( E \) has an order unit, the representation is equal to \( C(X) \). We denote by \( T \) the subset of the linear operators from \( E \) to \( F \) which consists of all those positive operators \( S \), for which \( S \) is s-absolutely continuous with respect to \( T \). Further, we denote the order ideal generated by a positive operator \( T \) by \( \langle T \rangle \) and the set of positive operators which are less than some multiple of \( T \) by \( \langle T \rangle^+ \). In what follows, we identify elements in a Banach lattice with a quasi-interior point with their representation as extended real valued functions. If \( S \) and \( T \) are positive operators from a Banach lattice \( E \) with a quasi-interior point \( e \) to a Banach lattice \( F \), the range of \( S \) and \( T \) is contained in the closure of the lattice generated by the supremum of \( Se \) and \( Te \). \( X \) will denote the representation space for \( E \) and \( Y \) the representation space for the Banach lattice generated by the supremum of \( Se \) and \( Te \).

2. ABSOLUTE CONTINUITY.

We begin with 2 elementary lemmas.

LEMMA 1. Let \( S \) and \( T \) be linear functionals on \( C(X) \), the set of continuous real valued functions on a compact Hausdorff space \( X \). Then \( S \) is s-absolutely continuous with respect to \( T \) if and only if the measure associated with \( S \) is absolutely continuous with respect to the measure associated with \( T \).

PROOF. We note that a linear functional \( \phi \) on \( R \) corresponds to multiplication, thus \( \phi(Tf_n) \) converges to 0 if and only if \( Tf_n \) converges to 0.
It is an easy exercise to see that $S$ is $s$-absolutely continuous to $T$ then the measure associated with $S$ is absolutely continuous with respect to the measure associated with $T$.

The converse is a simple application of the Radon-Nikodym Theorem.

**Lemma 2.** Let $E$ be a Banach lattice with quasi-interior point $e$ and let $\phi$ be a positive linear functional on $E$. Given a representation space $X$ for $E$, there exists a measure $u$ such that for each $g$ in $E$,

$$\phi(g) = \int g \, du.$$  

**Proof.** Since $C(X)$ is dense in $E$ and the sequence $\{g_n\}$ converges in norm to $g$ for $g$ non-negative, the sequence $\{\phi(g_n)\}$ converges to $\phi(g)$. It can be verified that the measure corresponding to the restriction of $\phi$ to $C(X)$ represents $\phi$.

We now give a sufficient condition for $s$-absolute continuity.

**Proposition 1.** Let $E$ be a Banach lattice with quasi-interior point $e$ and $F$ a Banach lattice with $S$, $T$ positive operators from $E$ to $F$. If for each positive decreasing sequence of functions $\{f_n\}$ in $E$ and for each $y$ in the representation space $Y$, the convergence of $Tf_n(y)$ to 0 implies the convergence of $Sf_n(y)$ to 0 then $S$ is $s$-absolutely continuous with respect to $T$.

**Proof.** Let $\phi$ be a linear functional on $F$ and $\{f_n\}$ be positive decreasing sequence such that $\phi(Tf_n)$ converges to 0. By lemma 2, we have a measure $u$ such that $\phi(g) = \int g \, du$. In particular we have that $\int Tf_n \, du$ converges to 0. For each $y$ in $Y$, define $h(y)$ by

$$h(y) = \inf \{Tf_n(y)\}.$$  

Thus $\int h \, du \leq \int Tf_n \, du$ for each $n$ or $\int h \, du = 0$. Setting $A = \{y \mid h(y) = 0\}$, we have $u(Y \setminus A) = 0$ and $\int_A Sf_n \, du = \int A Sf_n \, du$. Since $h(y) = 0$ on $A$ and $\{Tf_n(y)\}$ is decreasing, we have that $Tf_n(y)$ converges to 0 on $A$ and thus $Sf_n(y)$ converges to 0 by hypothesis. Since $Sf_n(y) \leq Sf(y)$ and $Sf(y)$ converges to 0 on $A$, the Monotone Convergence theorem implies

$$\lim \int Y Sf_n \, du = \lim \int A Sf_n \, du = 0.$$  

Thus we have that $\phi(Sf_n)$ converges to 0, that is that $S$ is $s$-absolutely continuous with respect to $T$.

We note that in the case when $F = C(Y)$, the converse of the proposition is also true since $y \circ T$ defines a positive linear functional on $F$.

It is obvious that if $S < T$ then $S$ is $s$-absolutely continuous with respect to $T$, i.e. contains $\langle T \rangle^*$. It is an easy exercise to show that $\mathcal{T}$ is closed and thus contains even the closure of $\langle T \rangle^*$.

**Proposition 2.** $\mathcal{T}$ is a closed subset of $L(E, F)$, the linear operators from $E$ to $F$ with respect to the operator norm. In particular, $\mathcal{T}$ contains the closure of $\langle T \rangle^*$.

We now compare and contrast these notions of order and absolute continuity when the range is an $M$-space.
THEOREM 1. Let $E$ be a Banach lattice with quasi-interior point and $S$, $T$ be positive operators from $E$ to $C(Y)$. Consider the conditions.

i) $S$ is $\tau$-absolutely continuous with respect to $T$ (in the sense of Luxemburg)
ii) $S$ is $\tau$-absolutely continuous with respect to $T$
iii) $S$ is $s$-absolutely continuous with respect to $T$
iv) $S$ is in the closure of $\langle T \rangle^+$.

Then we have

$$iv \Rightarrow iii \Rightarrow ii \Rightarrow i$$

and no other implications hold.

PROOF. That (iv) implies (iii) is Proposition 2. To show that (iii) implies (ii) we first note that if $S$ is $s$-absolutely continuous with respect to $T$ and $f \geq 0$, $Sf(y) > 0$ implies $Tf(y) > 0$. For a given $\varepsilon > 0$ and $g$ such that $0 < g \lesssim Sf$, let $A$ be the set $\{y \mid (g - \varepsilon)e(y) \geq 0\}$. Then $A$ is compact and hence there exists a $\lambda > 0$ such that $Tf \gtrsim \lambda(g - \varepsilon)e$. Therefore we have that $Tf \gtrsim \lambda(Sf - \varepsilon)e$ and thus $(Sf - \varepsilon)e \uparrow 0$ is in the order ideal generated by $Tf$ and therefore $Sf$ is in the uniform closure of the ideal generated by $Tf$. Thus we have (iii) implies (ii). That (ii) implies (i) follows from the fact that the closure of the ideal generated by $Tf$ is contained in the band generated by $Tf$.

That no other implications hold is shown by the following examples. We will assume that $C(X)$ is endowed with the sup-norm topology.

EXAMPLE 1. We give here operators $S$ and $T$ such that $S$ is absolutely continuous with respect to $T$, but $S$ is not $\tau$-absolutely continuous with respect to $T$.

Define $S$ and $T$ from $C[0,1]$ to $C[0,1]$ as follows.

\[
Sf(x) = f(x), \quad Tf(x) = xf(x)
\]

$Sf$ is in the band generated by $Tf$ and hence $S$ is absolutely continuous with respect to $T$.

However, for each operator $T'$ such that $T'f$ is in $\langle Tf \rangle$, we have for any positive $f$ in $C(X)$, $T'f(0) \lesssim \lambda Tf(0) = 0$, for some $\lambda$ in $R^+$, and thus $T'f(0) = 0$. Therefore,

\[
\|Sf - T'f\| \gtrsim \|Sf(0) - T'f(0)\| = |Sf(0)|.
\]

If $f(0) \neq 0$ then $Sf$ is not in the closure of the order ideal generated by $Tf$ and thus $S$ is not $\tau$-absolutely continuous with respect to $T$.

EXAMPLE 2. Here we give operators $S$ and $T$ such that $S$ is $\tau$-absolutely continuous with respect to $T$, but $S$ is not $s$-absolutely continuous with respect to $T$.

Let $N^*$ denote the one point compactification of $N$. Define operators from $C(N^*)$ to $C(N^*)$ as follows.
Since $Tf$ is constant, $Sf$ is less than some multiple of $Tf$, i.e. in the order ideal generated by $Tf$. Thus $S$ is $\tau$-absolutely continuous with respect to $T$.

However, by defining $f_k(x)$ on $N^*$ by

$$f_k(x) = X_{[k, \infty)}$$

we have a positive decreasing sequence of functions on $C(N^*)$ with $Tf_k(x)$ converging to 0 for each $x \in N^*$. However, $Sf_k(x) = 1$ for each $k$, and hence does not converge to 0. Thus $S$ is not $s$-absolutely continuous with respect to $T$.

EXAMPLE 3. Here we give operators $S$ and $T$ such that $S$ is $s$-absolutely continuous with respect to $T$, but where $S$ is not in the closure $\langle T \rangle^+$. We define operators from $C(N^*)$ to $C(N^*)$ as follows,

$$Sf = f$$

$$TF = \left\{ \sum_{n=1}^{\infty} \frac{[f(n)]}{n^2} \right\} I_n.$$ 

Suppose that $S$ is in the closure of $\langle T \rangle^+$. Let $T' \in \langle T \rangle^+$. For $x \in N^*$, we have for some $\lambda$ and for every $f \geq 0$ in $C(N^*)$,

$$T'f(x) < \lambda TF(x) = \lambda \left( \sum_{n=1}^{\infty} \frac{[f(n)]}{n^2} + f(\omega) \right) I_n$$

Pick $m$ such that $m^2 > 2\lambda$, and define a function $g$ by

$$g(x) = \begin{cases} 0 & \text{if } x \neq m, \\ 1 & \text{if } x = m. \end{cases}$$

We thus have $g \in C(N^*)$ and $\lVert g \rVert_{\omega} = 1$. In addition, for every $x \in N^*$,

$$T'g(x) < \lambda (1/m^2) < 1/2.$$ 

Thus,

$$\lVert S - T' \rVert \geq \lVert Sg - T'g \rVert \geq \lVert Sg(m) - T'g(m) \rVert > 1/2$$

and thus $S$ cannot be in the closure of the order ideal generated by $T$.

It is routine to check using Proposition 1 that $S$ is $s$-absolutely continuous with respect to $T$.

3. APPROXIMATIONS.

The next several theorems give approximations which enlarge the scope of previous results. Recall that a positive operator $T$ from a Banach lattice $E$ into itself is an orthomorphism if and only if there exists an element $m$ in $E$ such that $Tf = mf$ for each $f$ in $E$ where the elements are viewed in the representation (see e.g. [4], Thm. 4).
The next theorem is based on a result for operators $S$ which are $\tau$-absolutely continuous with respect to $T$ on Dedekind complete $\mathcal{M}$-spaces in [2] using a similar argument.

**THEOREM 2.** Let $E$ and $F$ be Banach lattices with quasi-interior points and let $S$, $T$ be positive operators from $E$ to $F$ such that $S$ is $s$-absolutely continuous with respect to $T$. Then for every $f$ in $E$, and every $\epsilon > 0$, there exist orthomorphisms $H_i$ on $E$ and $Q_i$ on $F$, for a finite number of indices $i$, such that

$$\| (S - \sum_{i=1}^{n} Q_i \circ T \circ H_i) f \| < \epsilon,$$

where $\| \cdot \|$ is the Banach space norm on $F$.

**PROOF.** If $e$ is a quasi-interior point of $E$ then for a given $f$ in $E$, we have that $e + f$ is also a quasi-interior point. Thus we can choose the representation space $X$ so that $f$ is in $C(X)$ and $Sf$ and $Tf$ are in $C(Y)$. Now, assume that $S$ is $s$-absolutely continuous with respect to $T$. For each fixed $y$ in $Y$, let $u_y$ and $v_y$ be the measures corresponding to the functionals $(y \circ T)$ and $(y \circ S)$, respectively. By the Riesz Representation Theorem,

$$Tf(y) = (y \circ T)(f) = \int f du_y$$

and

$$Sf(y) = (y \circ S)(f) = \int f dv_y.$$

As noted in Lemma 1, $v_y \ll u_y$ and thus we have by the Radon-Nikodym Theorem a positive measurable function $g_y$ on $X$ such that

$$Sf(y) = \int f g_y du_y.$$

Since $(y \circ S)$ is continuous, we have that $S(1) y \ll u_y$, and therefore $g_y$ is in $L^1(X, u_y)$. Given $\epsilon > 0$ and $f$ in $C(X)$, there is an $h_y$ in $C(X)$ such that

$$\| g_y - h_y \|_1 < \epsilon / \| f \|_1$$

(see [5], Thm 25.10).

Thus we have

$$\| T(h_y f) - Sf \|_1 = \| (h_y - g_y) f du_y \|_1$$

$$< \| h_y - g_y \|_1 \| f \|_1 < \epsilon.$$

Since $T$, $S$, $f$, $h_y$ are all continuous, there exists a neighborhood $N_y$ of $y$ such that for every $z$ in $N_y$,

$$\| T(h_y f) - Sf \|_1 < \epsilon.$$

For each $y$ in $Y$, choose such a neighborhood. Since $Y$ is compact there is a finite number of these neighborhoods which cover $Y$. We label the neighborhoods $N_i$ for $i = 1, 2, \ldots, n$. Further, functions $q_i$ in $C(Y)$ can be chosen (a partition of unity, see e.g. [6], p. 63) such that

$$0 \leq q_i \leq 1, \sum_{i=1}^{n} q_i = 1,$$

and $q_i(y) = 0$ on the complement of $N_i$. Let $h_i = h_y$, where $N_i = N_y$. 
Assume that \( z \) is in \( Y \) such that \( q_i(z) \neq 0 \). Then \( z \) is in \( N_i \) and

\[
|S f(z) - T(f h_i)(z)| < \epsilon
\]

and hence

\[
q_i(z) |S f(z) - T(f h_i)(z)| < \epsilon q_i(z).
\]

Therefore, summing up over the index \( i \), we have

\[
\sum_{i=1}^{n} |q_i(z) S f(z) - T(f h_i)(z)| < \epsilon \sum_{i=1}^{n} q_i(z).
\]

thus,

\[
|S f(z) - \sum_{i=1}^{n} q_i(z) T(f h_i)(z)| < \epsilon.
\]

Since \( z \) is arbitrary, this gives us

\[
\sum_{i=1}^{n} |q_i(z) S f(z) - T(f h_i)(z)| < \epsilon.
\]

We define orthomorphisms \( Q_i \) on \( C(Y) \) and \( H_i \) on \( C(X) \) by

\[
Q_i f(y) = q_i(y) f(y),
\]

\[
H_i f(x) = f(x) h_i(x).
\]

Thus we have by extending to \( E \) and \( F \) (e.g., see [2])

\[
\sum_{i=1}^{n} |Q_i o T H_i f| < \epsilon.
\]

Hence,

\[
|T f| < \epsilon \cdot 1,
\]

which implies for the Banach space norm,

\[
\|T f\| < \|\epsilon \cdot 1\| = \epsilon \cdot \|1\| = \epsilon.
\]

When the spaces involved are Dedekind complete, approximations of this type have generally been given using projection operators (e.g. [7], [8]).

**Corollary 1.** Let \( E, F, S, T \) be as in the theorem. If \( E \) and \( F \) are Dedekind complete, and if \( S \) is \( s \)-absolutely continuous with respect to \( T \) then, for each positive \( f \) in \( E \) and every \( \epsilon > 0 \), there exist projection operators \( Q_i \), \( H_i \) and real valued scalers \( a_i \) for a finite number of indices \( i \) such that

\[
\|T f\| < \epsilon.
\]

**Proof.** If \( C(X) \) is Dedekind complete then we have that \( X \) is extremally disconnected. In this case each simple function of the form \( a_i \chi_{Q_i} \) is continuous, if \( Q_i \) is open. Thus, following the proof of the Theorem we choose \( h_y \) to be a simple function of the form \( \sum_{i=1}^{n} a_i \chi_{H_i} \) with \( H_i \) open. Further, we choose \( q_i \) to be characteristic functions of clopen sets. Defining the operators \( H_i \) and \( Q_j \) as
we observe that each $Q_j$ and $H_1$ are projections. The remainder of the proof is similar to that of Theorem 2.

The next result, motivated by results which were established for operators $S$ which are in the ideal generated by $T$ (on $M$-spaces by Aliprantis and Burkinshaw [6] and on Banach lattices with quasi-interior points by Haid [9]), is a direct corollary of Theorem 2.

COROLLARY 2. Let $E$ and $F$ be Banach lattices with quasi-interior points and let $S$, $T$ be positive operators from $E$ to $F$ such that $S$ is $s$-absolutely continuous with respect to $T$. Then for every $f$ in $E$, a positive linear functional on $F$, and $\varepsilon > 0$, there exist orthomorphism $H_i$ on $E$ and $Q_i$ on $F$, for a finite number of indices $i$ such that

$$\phi (\| (S - \sum_{i=1}^{n} Q_i \circ T \circ H_i) f \|) < \varepsilon.$$ 

A further characterization of $s$-absolute continuity is given by the following.

THEOREM 3. Let $E$ and $F$ be Banach lattices with quasi-interior points and let $S$ and $T$ be positive operators from $E$ to $F$. Then $S$ is $s$-absolutely continuous with respect to $T$ if and only if, given $\varepsilon > 0$, $f$ in $E$ and $\phi$ a positive linear functional on $F$, there exists an orthomorphism $H$ on $E$ such that $\| \phi (TH - S) g \| < \varepsilon$ for all $g$ in $E$ with $\| g \| < \varepsilon$.

PROOF. Let $S$ be $s$-absolutely continuous with respect to $T$. If $e$ is a quasi-interior point of $E$ then so is $f + e$. We choose a representation space so that $F$ is in $C(X)$. For a linear functional $\phi$ we have that $\phi \circ S \ll \phi \circ T$ as measures on $X$ (see lemma 1). Thus if for every $h$ in $C(X)$ we have

$$\phi (\| (TH - S) g \|) < \varepsilon$$

then there is a positive measurable function $p'$ such that

$$\phi \circ S (h) = \int p' du.$$

Letting $h(x) = 1$ for every $x$, we see that $p'$ is $L^1(u)$, and so there exists a function $p$ in $C(X)$ such that $\| p - p' \|_1 < \varepsilon/\| f \|_\infty$. Therefore for $g$ such that $\| g \| < f$, we have

$$\| \phi (\| (TH - S) g \|) = \| \phi (g'p') du - \phi (g p - p') du \| \leq \| g'p - p' \|_1 \| g \|_\infty < \varepsilon.$$ 

Let $H$ be the orthomorphism defined by multiplication by $p$. Thus for every $g$ in $E$ with $\| g \| < f$, we have that

$$\| \phi (TH - S) g \| < \varepsilon.$$ 

Conversely, let $\{f_n\}$ be a positive decreasing sequence in $E$ such that $\phi (T_f)$ converges to 0. Again choosing $X$ so that $f_1$ is in $C(X)$, we have $\{f_n\}$ in
C(X). By assumption, given $\epsilon > 0$, there exists an orthomorphism $H$ on $E$ so that $|\phi(TH - S)f_n| < \epsilon$ for every $n$. Recall that $H$ is a multiplication operator, say multiplication by $p$ in $C(X)$. Now $(\phi \circ T)$ is a positive linear functional on $C(X)$ corresponding to a measure, say $u$. Since $\phi(Tf_n) = \int f_n du$ converges to 0, it follows that $\int f_n p du = \phi(Tf_n)$ converges to 0. Thus $\phi(Sf_n)$ also converges to 0 and so $S$ is $s$-absolutely continuous with respect to $T$.

For compact operators on $M$-spaces, we have the following which is based on a result for Dedekind complete spaces in [2].

**Theorem 4.** Let $X, Y$ be compact Hausdorff spaces and $S, T$ be positive operators from $C(X)$ to $C(Y)$. If $S$ is $s$-absolutely continuous with respect to $T$ and $T$ is compact, then $S$ is compact if and only if $S$ is the norm limit of operators of the type $\sum_{i=1}^{n} Q_i \circ T_0 H_i$, for a finite number of indices and each $Q_i$ and $H_i$ is an orthomorphism.

**Proof.** If $T$ is compact then each operator of the form $Q_i \circ T_0 H_i$ is compact and hence so is the finite sum $\sum_{i=1}^{n} Q_i \circ T_0 H_i$, and thus $S$ is compact.

For the converse, we assume that $S$ is compact. For every $y$ in $Y$ and $\epsilon > 0$, denote by $G$ the operator defined by

$$GF = SF - T(h_y f),$$

where $h_y$ is the continuous function as described in the proof of Theorem 2. Letting $H_y$ be the orthomorphism on $C(X)$ defined by multiplication by $h_y$, we have that $G$ is compact, since both $S$ and $T h_y$ are compact. Further, as in the proof of Theorem 2, we have

$$||GF(\epsilon)|| < \epsilon.$$

We will show that there is a neighborhood $N_y$ of $y$ such that $Gf(N_y)$ is contained in $(-3\epsilon, 3\epsilon)$ for all $f$ in $C(X)$ such that $||f||_\infty \leq 1$.

Assume that this is not the case. Then there exists a net $(y_\alpha)$ in $Y$ such that $y_\alpha$ converges to $y$, and there exist functions $f_\alpha$ in $C(X)$ with $||f_\alpha||_\infty \leq 1$ and satisfying both of the following

1) $Gf_\alpha(y_\alpha) > 3\epsilon$, for all $\alpha$.
2) $Gf_\alpha(y) < \epsilon$.

Since $G$ is compact, there exists a subnet of $(Gf_\alpha)$ converging to some function $g'$ in $C(Y)$. However, from condition ii) we have

$$g'(z) < 3\epsilon/2$$

for all $z$ in some neighborhood $W$ of $y$, while from condition i) we see that

$$g'(y_\alpha) > 3\epsilon$$

for all $y_\alpha$ in $W$, giving us a contradiction.

Therefore, there exists a neighborhood $N_y$ of $y$ such that $Gf(N_y)$ is contained in $(-3\epsilon, 3\epsilon)$, for all $f$ with $||f||_\infty \leq 1$. Repeating the construction
process of Theorem 2, we find a partition of unity \( \{q_i\} \) for a cover \( \{N_i\} \) of \( Y \) such that

\[
0 \leq q_i \leq 1, \quad \sum_{i=1}^{n} q_i = 1, \quad \text{and} \quad q_i(y) = 0 \quad \text{on the complement of} \quad N_i.
\]

Thus we have

\[
\|S - \sum_{i=1}^{n} Q_i \otimes T_{0H_1}\| = \sup \{ \|Sf - \sum_{i=1}^{n} (Q_i \otimes T_{0H_1})f\|_{\infty} \} < 3\varepsilon
\]

and thus \( S \) is the norm limit of operators of the type \( \sum_{i=1}^{n} Q_i \otimes T_{0H_1} \).

We further note that the approximation given in Theorem 2 is not, in general, uniform. Let \( E = F = C(\mathbb{N}^*) \) and define \( Sf(x) = f(x) \) and \( Tf(x) = (\sum_{n=1}^{\infty} f(n)/n^2 + f(\omega))1 \). As stated earlier \( S \) is \( s \)-absolutely continuous with respect to \( T \). \( T \) is compact (it has rank 1), but \( S \) is not compact. If the approximation given in Theorem 2 were uniform, then Theorem 4 would imply \( S \) is compact.
