EXPONENTIALLY FITTED SPLINE APPROXIMATION
METHOD FOR SOLVING SELFADJOINT SINGULAR
PERTURBATION PROBLEMS

MOHAN K. KADALBAJOO and KAILASH C. PATIDAR

Received 5 December 2001

A numerical method based on cubic spline with exponential fitting factor is given
for the selfadjoint singularly perturbed two-point boundary value problems. The
scheme derived in this method is second-order accurate. Numerical examples are
given to support the predicted theory.

2000 Mathematics Subject Classification: 65L10, 65D07, 65B99, 34B05.

1. Introduction. We consider the following selfadjoint singularly perturbed
two-point boundary value problem:

\[ Ly = -\varepsilon (a(x)y')' + b(x)y = f(x) \quad \text{on } (0,1), \]
\[ y(0) = \eta_0, \quad y(1) = \eta_1, \]  \hspace{1cm} (1.1)

where \( \eta_0, \eta_1 \) are given constants and \( \varepsilon \) is a small positive parameter. Further,
the coefficients \( f(x), a(x), \) and \( b(x) \) are smooth functions and satisfy

\[ a(x) \geq a > 0, \quad a'(x) \geq 0, \quad b(x) \geq b > 0. \] \hspace{1cm} (1.2)

Under these conditions, the operator \( L \) admits a maximum principle [8].

The problems in which a small parameter multiplies to a highest derivative
arise in various fields of science and engineering, for instance, fluid mechanics,
fluid dynamics, elasticity, quantum mechanics, chemical reactor theory,
hydrodynamics, and so forth.

Out of the three principal approaches to solve such problems numerically,
namely, the finite-difference methods, the finite-element methods, and the
spline approximation methods, the first two have been used by several authors.
Nijijima [6] gave uniformly second-order accurate difference schemes whereas
Miller [5] gave sufficient conditions for the uniform first-order convergence of
a general three-point difference scheme. Boglaev [3] and Schatz and Wahlbin
[9] used finite-element techniques to solve such problems. It is known that the
most classical methods fail when \( \varepsilon \) is small relative to the mesh width \( h \) that
is used for discretization of the operator \( L \).
In this paper, we have used the third approach, namely, the spline approximation method, to solve problems of type (1.1). There are two possibilities to obtain small truncation error inside the boundary layer(s). The first is to choose a fine mesh there, whereas the second one is to choose a difference formula reflecting the behaviour of the solution(s) inside the boundary layer(s). The present work deals with the second approach, whereas the first one is currently under the investigation of the authors.

We have reduced the original problem (i.e., problem (1.1)) to the normal form. In the normalized form, we replace the perturbation parameter $\varepsilon$ affecting the highest derivative by a fitting factor $\sigma(x, \varepsilon)$. Using cubic spline, this factor is determined in such a way that the truncation error of the corresponding scheme for the boundary layer function(s), in the case of constant coefficients, should be equal to zero. This procedure is known as the exponential fitting or the introducing of artificial viscosity [2, 4]. By making use of the continuity of the first-order derivative of the spline function, the resulting spline difference scheme gives a tridiagonal system which can be solved efficiently by the well-known algorithms.

In Section 2, we give a brief description of the method. The derivation of the difference scheme has been given in Section 3. The fitting factor is determined in Section 4, whereas the second-order accuracy of the method is shown in Section 5. To demonstrate the applicability of the proposed method, four numerical examples have been solved in Section 6 and the results are presented along with their comparison with those obtained by other authors. Finally, the discussion on these numerical results, along with some comparisons with the results obtained earlier by others, is presented in Section 7.

2. Description of the method. Rewrite (1.1) as

$$y'' + P(x)y' + Q(x)y = R(x),$$

(2.1)

where

$$P(x) = \frac{a'(x)}{a(x)}, \quad Q(x) = -\frac{b(x)}{\varepsilon a(x)}, \quad R(x) = -\frac{f(x)}{\varepsilon a(x)}.$$  

(2.2)

Let

$$y(x) = U(x)V(x),$$  

(2.3)

and transform (2.1) into the normal form, that is,

$$V'' + A(x)V = B(x).$$  

(2.4)
where

\[ A(x) = Q(x) - \frac{1}{2} P'(x) - \frac{1}{4} (P(x))^2, \]

\[ B(x) = R(x) \exp \left( \frac{1}{2} \int P(x) \, dx \right), \]

\[ U(x) = \exp \left( -\frac{1}{2} \int P(x) \, dx \right), \quad x \in (0,1), \]

with

\[ V(0) = \frac{\gamma(0)}{U(0)} = \alpha_0, \quad V(1) = \frac{\gamma(1)}{U(1)} = \alpha_1, \quad \alpha_0, \alpha_1 \in \mathbb{R}. \]

Multiplying (2.4) throughout by \(-\varepsilon\) (where \(0 < \varepsilon \leq 1\)), we get

\[ -\varepsilon V'' + W(x)V = Z(x), \]

\[ V(0) = \alpha_0, \quad V(1) = \alpha_1, \]

where

\[ W(x) = -\varepsilon A(x), \quad Z(x) = -\varepsilon B(x). \]

We define the fitting comparison problem associated with (2.7) by

\[ -\sigma(x, \varepsilon)V'' + W(x)V = Z(x), \]

\[ V(0) = \alpha_0, \quad V(1) = \alpha_1, \]

where \( \sigma(x, \varepsilon) \) is an exponential fitting factor which is to be determined subsequently.

The approximate solution of problem (2.9) is sought in the form of the cubic spline function \( S_j(x) \), which is defined as follows: let

\[ x_0 = 0, \quad x_j = x_0 + jh, \quad j = 1(1)n, \quad h = x_j - x_{j-1}, \quad x_n = 1. \]

For the values \( V(x_0), V(x_1), \ldots, V(x_n) \), there exists an interpolating cubic spline with the following properties:

(i) \( S_j(x) \) coincides with a polynomial of degree 3 on each interval \([x_{j-1}, x_j]\), \( j = 1(1)n \);

(ii) \( S_j(x) \in C^2[0,1] \);

(iii) \( S_j(x_j) = V(x_j), \quad j = 0(1)n. \)

Hence, analogous to [1], the cubic spline can be given as

\[ S_j(x) = \frac{(x_j-x)^3}{6h}M_{j-1} + \frac{(x-x_{j-1})^3}{6h}M_j + \left( V_{j-1} - \frac{h^2 M_{j-1}}{6} \right) \left( \frac{x_j-x}{h} \right) + \left( V_j - \frac{h^2 M_j}{6} \right) \left( \frac{x-x_{j-1}}{h} \right), \]
where
\[ x \in [x_{j-1}, x_j], \quad h = x_j - x_{j-1}, \quad j = 1, 2, \ldots, n, \]
\[ M_j = S''_j(x_j), \quad j = 0, 1, \ldots, n. \]  
(2.12)

Using this spline function, we will derive the difference scheme in Section 3, which will give us the approximate solution of \( V(x) \). Since \( U(x) \) is known, therefore the solution to the original problem will be obtained using (2.3).

3. Derivation of the scheme. Differentiating (2.11) and denoting the approximate solution to \( V(x) \) by \( \nu(x) \), we get
\[
S_j'(x) = -\frac{(x_j-x)^2}{2h}M_{j-1} + \frac{(x-x_{j-1})^2}{2h}M_j \\
+ \left( \frac{\nu_j-\nu_{j-1}}{h} \right) - \left( \frac{M_j-M_{j-1}}{6} \right)h.
\]  
(3.1)

Since \( S_j(x) \in C^2[0,1] \), therefore we must have
\[ S_j'(x_j) = S'_{j+1}(x_j). \]  
(3.2)

Using (3.1), (3.2), and (2.9), we obtain the difference scheme
\[
R\nu_j = QZ_j, \quad j = 1, 2, \ldots, n - 1,
\]  
(3.3)

where
\[
R\nu_j = r^-_j \nu_{j-1} + r^+_j \nu_j + r^c_j \nu_{j+1},
\]  
(3.4)
\[
QZ_j = q^-_j Z_{j-1} + q^+_j Z_j + q^c_j Z_{j+1},
\]  
(3.5)
\[
\nu_0 = \alpha_0, \quad \nu_n = \alpha_1,
\]  
(3.6)
\[
r^-_j = -1 \left( 1 - \frac{h^2 W_{j-1}}{6\sigma^-_j} \right) \frac{1}{h}, \quad r^+_j = -1 \left( 1 - \frac{h^2 W_{j+1}}{6\sigma^+_j} \right) \frac{1}{h}, \quad r^c_j = 2 \left( 1 + \frac{h^2 W_j}{3\sigma^c_j} \right) \frac{1}{h},
\]  
(3.7)
\[
q^-_j = \frac{h}{6\sigma^-_j}, \quad q^+_j = \frac{h}{6\sigma^+_j}, \quad q^c_j = \frac{2h}{3\sigma^c_j},
\]  
(3.8)

where \( \sigma^-_j = \sigma_{j-1}, \sigma^+_j = \sigma_{j+1}, \sigma^c_j = \sigma_j \), and \( \sigma_j \) is to be determined.

**Remark 3.1.** The scheme without using fitting factor will be given by
\[
r^-_j = -1 \left( 1 - \frac{h^2 W_{j-1}}{6\varepsilon} \right) \frac{1}{h}, \quad r^+_j = -1 \left( 1 - \frac{h^2 W_{j+1}}{6\varepsilon} \right) \frac{1}{h}, \quad r^c_j = 2 \left( 1 + \frac{h^2 W_j}{3\varepsilon} \right) \frac{1}{h},
\]  
(3.9)
4. Determination of the fitting factor. In order to get a suitable fitting factor $\sigma(x, \varepsilon)$, we will use the following lemma.

**Lemma 4.1 [4].** Let $V(x) \in C^4[0,1]$. Let $W''(0) = W'(1) = 0$. Then the solution of problem (2.7) has the form

$$V(x) = d(x) + e(x) + g(x),$$  \hspace{1cm} (4.1)

where

$$d(x) = q_0 \exp \left[ -x \left( \frac{W(0)}{\varepsilon} \right)^{1/2} \right],$$  \hspace{1cm} (4.2)

$$e(x) = q_1 \exp \left[ -(1-x) \left( \frac{W(1)}{\varepsilon} \right)^{1/2} \right],$$  \hspace{1cm} (4.2)

$q_0$ and $q_1$ are bounded functions of $\varepsilon$ independent of $x$ and

$$|g^{(k)}(x)| \leq N(1 + (\varepsilon)^{1-k/2}), \hspace{0.5cm} k = 0, 1, 2, 3, 4 \hspace{1cm} (4.3)$$

$N$ is a constant independent of $\varepsilon$.

The matrix of the system (3.3) is inverse monotone if $h^2W_i/6\sigma_i \leq 1$, $i = j$, $j \pm 1$. Thus, we take a fitting factor in the following way:

$$\sigma^-_j = \frac{h^2W_{j-1}}{6} \mu(\rho), \hspace{0.5cm} \sigma^+_j = \frac{h^2W_{j+1}}{6} \mu(\rho), \hspace{0.5cm} \sigma^c_j = \frac{h^2W_j}{6} \mu(\rho),$$  \hspace{1cm} (4.4)

where $\mu(\rho)$ (with $\rho$ at $x_j$ given by $\rho_j = \sqrt{W_j/\varepsilon}$) is to be determined.

We require that the truncation error for the boundary layer functions should be equal to zero when $W(x) = W = \text{constant}$.

From the condition $Rd_j = 0$ for $W(x) = W = \text{constant}$, we have

$$\mu(\rho) = 1 + \frac{3}{2 \sin h^2(\rho h/2)}. \hspace{1cm} (4.5)$$

The condition $Re_j = 0$ for $W(x) = W = \text{constant}$ will give the same $\mu(\rho)$. Therefore, we define

$$\mu(\rho) = 1 + \frac{3}{2 \sin h^2(\rho h/2)}, \hspace{1cm} \text{when } W(x) = W = \text{constant},$$

$$\mu(\rho) = 1 + \frac{3}{2 \sin h^2(\rho_j h/2)}, \hspace{1cm} \text{when } W(x) \neq \text{constant}. \hspace{1cm} (4.6)$$

Hence, the variable fitting factor $\sigma_j$ is defined as

$$\sigma_j = \frac{h^2W_j}{6} \mu(\rho_j). \hspace{1cm} (4.7)$$
5. **Proof of the uniform convergence.** Throughout the paper, $M$ will denote a positive constant which may take different values in different equations (inequalities) but are always independent of $h$ and $\varepsilon$.

The scheme (3.3), (3.8) can be written in the matrix form

$$Av = Z,$$

(5.1)

where $A$ is a matrix of the system (3.3) and $v$ and $Z$ are corresponding vectors.

Now, the local truncation error $\tau_j(\phi)$ of the scheme (3.3) is defined by

$$\tau_j(\phi) = R\phi_j - Q(L\phi)_j,$$

(5.2)

where $\phi(x)$ is an arbitrary sufficiently smooth function.

Therefore,

$$\tau_j(V) = RV_j - Q(LV)_j = R(V_j - \nu_j)$$

$$\Rightarrow \max_j |V_j - \nu_j| \leq ||A^{-1}|| \max_j |\tau_j(V)|.$$

(5.3)

In order to estimate the values $|V_j - \nu_j|$, we will estimate the truncation error $\tau_j(V)$ and the norm of the matrix $A^{-1}$.

From (4.7), it is obvious that

$$0 \leq \sigma_j \leq Mh^2 \Rightarrow |\sigma_j - \varepsilon| \leq Mh^2 \text{ for } \varepsilon \leq Ch^2,$$

(5.4)

where $C$ is some positive constant. Now, for the case $Ch^2 \leq \varepsilon$, we see that

$$\sigma_j - \varepsilon = \frac{h^2W_j}{6} + \varepsilon\left[\frac{(h\rho_j/2)^2}{\sinh^2(h\rho_j/2)} - 1\right] \Rightarrow |\sigma_j - \varepsilon| \leq Mh^2 \text{ for } Ch^2 \leq \varepsilon.$$

(5.5)

Hence,

$$|\sigma_j - \varepsilon| \leq Mh^2,$$

(5.6)

that is, $\sigma_j$ approximates $\varepsilon$ with the error $O(h^2)$.

**Estimation of truncation error and the norm of $A^{-1}$.** From Lemma 4.1, we have

$$\tau_j(V) = \tau_j(d) + \tau_j(e) + \tau_j(g).$$

(5.7)

We will estimate separately the parts of $\tau_j(V)$.

First, we consider the case in which $Ch^2 \leq \varepsilon$. 
We will start with \( d(x) \). We calculate
\[
R dj = r^j_j d_{j-1} + r^j_j d_j + r^j_{j+1} d_{j+1}
\]
(5.8)
\[
Q(Ld) j = a^j_j Z_{j-1} + a^j_j Z_j + a^j_{j+1} Z_{j+1}
= a^j_j ( - \varepsilon d''_{j-1} + W_{j-1} d_{j-1} ) \\
+ a^j_j ( - \varepsilon d''_{j} + W_j d_j ) + a^j_{j+1} ( - \varepsilon d''_{j+1} + W_{j+1} d_{j+1} ).
\]
(5.9)

Now, from Lemma 4.1, we have
\[
d(x) = q_0 \exp \left[ - x \left( \frac{W(0)}{\varepsilon} \right)^{1/2} \right]
\]
(5.10)
implies
\[
d_{j-1} = d_j \exp \left( h \sqrt{\frac{W_0}{\varepsilon}} \right), \quad d_{j+1} = d_j \exp \left( - h \sqrt{\frac{W_0}{\varepsilon}} \right),
\]
(5.11)
\[
d''_{j-1} = \left( \frac{W_0}{\varepsilon} \right) d_j \exp \left( h \sqrt{\frac{W_0}{\varepsilon}} \right), \quad d''_{j+1} = \left( \frac{W_0}{\varepsilon} \right) d_j \exp \left( - h \sqrt{\frac{W_0}{\varepsilon}} \right),
\]
(5.12)
\[
d'' = \left( \frac{W_0}{\varepsilon} \right) d_j.
\]
(5.13)

Putting all these expressions into (5.8) and (5.9), and since
\[
\tau_j(d) = Rd_j - Q(Ld) j,
\]
(5.14)
we get
\[
\tau_j(d) = d_{j-1} \left( \frac{1}{h} + \frac{hW_0}{6\sigma^j_j} \right) + d_j \left( \frac{2}{h} + \frac{2hW_0}{3\sigma^j_j} \right) + d_{j+1} \left( \frac{1}{h} + \frac{hW_0}{6\sigma^j_{j+1}} \right).
\]
(5.15)

From (5.6), \( \sigma_j = \varepsilon + O(h^2) \), and using the above expressions for \( d_{j-1} \) and \( d_{j+1} \), we have
\[
| \tau_j(d) | \leq \frac{M h^3 d_j}{\varepsilon^2}.
\]
(5.16)
But the expression for \( d(x) \) involves \( q_0 \) in the numerator, which is a bounded function of \( \varepsilon \) independent of \( x \). Therefore, we get
\[
| \tau_j(d) | \leq \frac{M h^3}{\varepsilon}.
\]
(5.17)

Now
\[
e(x) = q_1 \exp \left[ - (1 - x) \left( \frac{W(1)}{\varepsilon} \right)^{1/2} \right]
\]
(5.18)
implies
\[ e_{j-1} = e_j \exp \left( -h \sqrt{\frac{W_1}{\varepsilon}} \right), \quad e_{j+1} = e_j \exp \left( h \sqrt{\frac{W_1}{\varepsilon}} \right), \] (5.19)
\[ e_{j-1}' = \left( \frac{W_1}{\varepsilon} \right) e_j \exp \left( -h \sqrt{\frac{W_1}{\varepsilon}} \right), \quad e_{j+1}' = \left( \frac{W_1}{\varepsilon} \right) e_j \exp \left( h \sqrt{\frac{W_1}{\varepsilon}} \right), \] (5.20)
\[ e_j'' = \left( \frac{W_1}{\varepsilon} \right) e_j, \] (5.21)
and the similar construction as was for \( d(x) \) will give us
\[ \left| \tau_j(e) \right| \leq \frac{Mh^3}{\varepsilon}. \] (5.22)
Now,
\[ \tau_j(g) = Rg_j - Q(Lg)_j \] (5.23)
implies
\[ \tau_j(g) = -\frac{1}{h} (g_{j-1} - 2g_j + g_{j+1}) + \frac{\varepsilon h}{6} \left( \frac{g''_{j-1}}{\sigma_j} + \frac{4g''_{j}}{\sigma_j^2} + \frac{g''_{j+1}}{\sigma_j^3} \right). \] (5.24)
Expanding \( g_{j-1}, g_{j+1}, \) and their derivatives in terms of \( g_j \) and its derivatives, and using (5.6), we get
\[ \left| \tau_j(g) \right| \leq Mh^3 \left| g^{(iv)}_j \right|. \] (5.25)
Therefore, using Lemma 4.1, we obtain
\[ \left| \tau_j(g) \right| \leq \frac{Mh^3}{\varepsilon}. \] (5.26)
From (5.17), (5.22), and (5.26), we have
\[ \left| \tau_j(V) \right| \leq \frac{Mh^3}{\varepsilon} \quad \text{when } Ch^2 \leq \varepsilon. \] (5.27)
Now we consider the case in which \( Ch^2 \geq \varepsilon. \)
We introduce the notations
\[ r_j^- = r_j^- (W_{j-1}), \quad r_j^+ = r_j^+ (W_{j+1}), \quad r_j^c = r_j^c (W_j), \]
\[ a_j^- = a_j^- (W_{j-1}), \quad a_j^+ = a_j^+ (W_{j+1}), \quad a_j^c = a_j^c (W_j). \] (5.28)
Since we have determined \( \sigma(x, \varepsilon) \) in such a way that the truncation error for the boundary layer function(s) is equal to zero in the case of \( W(x) = W = \text{constant}, \)
thus \( \tau_j(d) = 0 \) when \( W(x) = W = \text{constant} \). We will denote this expression by \( \tilde{\tau}_j(d) \). Therefore,

\[
\tau_j(d) = \tau_j(d) - \tilde{\tau}_j(d)
\]

\[
= \left[ \{ r_j^-(W_{j-1}) - r_j^-(W_0) \} - \{ q_j^- (W_{j-1}) - q_j^- (W_0) \} (W_{j-1} - W_0) \right] d_{j-1}
\]

\[
+ \left[ \{ r_j^c(W_j) - r_j^c(W_0) \} - \{ q_j^c (W_j) - q_j^c (W_0) \} (W_j - W_0) \right] d_j
\]

\[
+ \left[ \{ r_j^+ (W_{j+1}) - r_j^+ (W_0) \} - \{ q_j^+ (W_{j+1}) - q_j^+ (W_0) \} (W_{j+1} - W_0) \right] d_{j+1}.
\]

(5.29)

Using (3.8) and (5.6), and since

\[
|W_{j-1} - W_0| \leq Mx_j^2, \quad |W_j - W_0| \leq Mx_j^2, \quad |W_{j+1} - W_0| \leq Mx_{j+1}^2,
\]

(5.30)

we obtain

\[
|\tau_j(d)| \leq \frac{M}{h} [x_{j-1}^2 d_{j-1} + x_j^2 d_j + x_{j+1}^2 d_{j+1}].
\]

(5.31)

Now, using the fact that (see, e.g., Doolan et al. [4])

\[
x \exp\left(-\frac{cX}{\varepsilon}\right) \leq M \left(\frac{\varepsilon}{c}\right) \exp\left(-\frac{cX}{2\varepsilon}\right)
\]

(5.32)

and \( d_j \)'s involve \( q_0 \) which is a bounded function of \( \varepsilon \), we obtain

\[
x_{j-1}^2 d_{j-1} \leq M\varepsilon^2, \quad x_j^2 d_j \leq M\varepsilon^2, \quad x_{j+1}^2 d_{j+1} \leq M\varepsilon^2.
\]

(5.33)

Hence,

\[
|\tau_j(d)| \leq \frac{M\varepsilon^2}{h}.
\]

(5.34)

But

\[
\varepsilon < 1 \Rightarrow \varepsilon^2 < \varepsilon,
\]

(5.35)

therefore,

\[
|\tau_j(d)| \leq \frac{M\varepsilon}{h}
\]

(5.36)

implies

\[
|\tau_j(d)| \leq Mh \quad (\text{since } \varepsilon \leq Ch^2).
\]

(5.37)

Similarly, we obtain

\[
|\tau_j(e)| \leq Mh.
\]

(5.38)
Now, for $\tau_j(g)$, we use the form
\[
\tau_j(g) = \frac{\xi}{h} \left(g_j'' + 4g_j' + g_{j+1}'\right) + hg''(\xi) : x_{j-1} < \xi < x_{j+1}.
\] (5.39)
Therefore, using Lemma 4.1, we obtain
\[
|\tau_j(g)| \leq Mh. \tag{5.40}
\]
From (5.37), (5.38), and (5.40), we have
\[
|\tau_j(V)| \leq Mh. \tag{5.41}
\]

**Estimate of $\|A^{-1}\|$.** Following Varah [10], we see that
\[
| -r_j^- + r_j^c - r_j^+ | = \left| \frac{1}{h} - \frac{hW_{j-1}}{6\sigma_j} + \frac{2}{h} + \frac{2hW_j}{3\sigma_j^c} + \frac{1}{h} - \frac{hW_{j+1}}{6\sigma_j^+} \right|
\]
\[
= \left| \frac{4}{h} - \frac{h}{6} (W_{j-1} - 4W_j + W_{j+1}) \right| \frac{1}{\varepsilon + O(h^2)} \tag{5.42}
\]
using (5.6),
\[
| -r_j^- + r_j^c - r_j^+ | \geq \begin{cases} \frac{M_1 h}{\varepsilon}, & Ch^2 \leq \varepsilon, \\ \frac{M_1}{h}, & Ch^2 \geq \varepsilon, \end{cases} \tag{5.43}
\]
implies
\[
\|A^{-1}\| \leq \begin{cases} \frac{M_2 \varepsilon}{h}, & Ch^2 \leq \varepsilon, \\ M_2 h, & Ch^2 \geq \varepsilon, \end{cases} \tag{5.44}
\]
where $M_1$ and $M_2 (= 1/M_1)$ are constants independent of $h$ and $\varepsilon$.

From (5.3), (5.27), (5.41), and (5.44), we have the following theorem.

**Theorem 5.1.** Let $W(x), Z(x) \in C^2[0,1]$, $W(x) \geq W > 0$, and $W'(0) = W'(1) = 0$. Let $\nu_j, j = 0, 1, \ldots, n$ be the approximate solution of (2.7), obtained using (3.3) and (3.8). Then, there is a constant $M$ independent of $\varepsilon$ and $h$ such that
\[
\max_j |V(x_j) - \nu_j| \leq Mh^2. \tag{5.45}
\]

**6. Test examples and numerical results.** In this section, we present some numerical results which illustrate Theorem 5.1.
Example 6.1 [11]. Consider problem (1.1) with
\[
a(x) = 1, \quad b(x) = 1 + x(1 - x)
\]
\[
f(x) = 1 + x(1 - x) + [2\sqrt{\varepsilon} - x^2(1 - x)] \exp \left[ -\frac{1 - x}{\sqrt{\varepsilon}} \right]
\]
\[
+ [2\sqrt{\varepsilon} - x(1 - x)^2] \exp \left[ -\frac{x}{\sqrt{\varepsilon}} \right]
\]
\[
y(0) = 0, \quad y(1) = 0.
\]
Its exact solution is given by
\[
y' = 1 + (x - 1) \exp \left[ -\frac{x}{\sqrt{\varepsilon}} \right] - x \exp \left[ -\frac{1 - x}{\sqrt{\varepsilon}} \right].
\]

Example 6.2 [7]. Consider problem (1.1) with
\[
a(x) = 1, \quad b(x) = \frac{4}{(x + 1)^4} \left[ 1 + \sqrt{\varepsilon}(x + 1) \right],
\]
\[
f(x) = -\frac{4}{(x + 1)^4} \left[ 1 + \sqrt{\varepsilon}(x + 1) + 4\varepsilon^2 \cos \left( \frac{4\pi x}{x + 1} \right) \right]
\]
\[
- 2\pi \varepsilon(x + 1) \sin \left( \frac{4\pi x}{x + 1} \right) + \frac{3}{1 - \exp \left( -1/\sqrt{\varepsilon} \right)} \right],
\]
\[
y(0) = 2, \quad y(1) = -1.
\]
Its exact solution is given by
\[
y(x) = -\cos \left( \frac{4\pi x}{x + 1} \right) + \frac{3}{1 - \exp \left( -1/\sqrt{\varepsilon} \right)}.
\]

Example 6.3 [4]. Consider problem (1.1) with
\[
a(x) = 1 + x^2, \quad b(x) = \frac{\cos x}{(3 - x)^3},
\]
\[
f(x) = 4(3x^2 - 3x + 1) \left( x - \frac{1}{2} \right)^2 + 2,
\]
\[
y(0) = -1, \quad y(1) = 0.
\]
Its exact solution is not available.

Example 6.4 [9]. Consider problem (1.1) with
\[
a(x) = 1, \quad b(x) = \frac{1}{\varepsilon},
\]
\[
f(x) = \frac{1}{\varepsilon} \left( x - 1 - x \exp \left( -\frac{1}{\sqrt{\varepsilon}} \right) \right),
\]
\[
y(0) = 0, \quad y(1) = 0.
\]
Its exact solution is given by
\[
y(x) = x - 1 - x \exp \left( -\frac{1}{\sqrt{\varepsilon}} \right) + \exp \left( -\frac{x}{\sqrt{\varepsilon}} \right).
\]

Tables 6.1, 6.2, 6.5, and 6.8 contain the maximum errors at all the mesh points:

$$\max_j |y(x_j) - \tilde{v}(x_j)|$$  \hspace{1cm} (6.8)
for different \( n \) and \( \epsilon \), where \( \tilde{\nu}(x_j) \) is the approximate solution of (1.1) obtained via (2.7) and (2.3).

Table 6.6 contains maximum errors based on the double-mesh principle (Doolan et al. [4]) (as for Example 6.3, the exact solution is not available):

\[
\max_{0 \leq j \leq n} |\tilde{\nu}^n_j - \tilde{\nu}^{2n}_{2j}|, \quad n = 8, 16, 32, 64, 128, 256.
\]

</table>

Tables 6.3 and 6.7 contain the numerical rate of uniform convergence for Examples 6.1 and 6.3, respectively, which is determined as in [4]:

\[
r_{k,\epsilon} = \log_2 \left( \frac{z_{k,\epsilon}}{z_{k+1,\epsilon}} \right), \quad k = 0, 1, 2, \ldots,
\]

where

\[
z_{k,\epsilon} = \max_j \left| \tilde{\nu}_{j}^{h/2^k} - \tilde{\nu}_{2j}^{h/2^{k+1}} \right|, \quad k = 0, 1, 2, \ldots,
\]

and \( \tilde{\nu}_{j}^{h/2^k} \) denotes the value of \( \tilde{\nu}_j \) for the mesh length \( h/2^k \).

7. Discussion. We have described a numerical method for solving self-adjoint singular perturbation problem using cubic spline with exponential fitting. It is a practical method and can easily be implemented on a computer to solve such problems. The method has been analyzed for convergence. Four
examples have been solved to demonstrate the applicability of the proposed method.

For Examples 6.1 and 6.3, we have computed the rate of convergence, see Tables 6.3 and 6.7 which show the uniform second-order convergence as predicted in the theory. The same can be seen for the other examples also.

As is seen from Tables 6.1 and 6.2, the results obtained using fitting factor are better than those without using fitting factor.

Example 6.2 has been solved earlier by O’Riordan and Stynes [7]. We obtain better results than those in [7]. Using finite-element techniques, Schatz and
Wahlbin [9] have solved Example 6.4. Table 6.8 shows (quite graphically) how badly standard methods can perform.

To further corroborate the applicability of the proposed method, graphs have been plotted for Examples 6.1 and 6.2 for values of \( x \in [0, 1] \) versus the computed (termed as approximate) solution obtained at different values of \( x \) for a fixed \( \varepsilon \). For each plot, we took \( n = 20 \) and 40 for Examples 6.1 and 6.2, respectively. Figures 7.1 and 7.3 are the graphs without using fitting factor for Example 6.1 for \( \varepsilon = 0.001 \) and \( \varepsilon = 0.0005 \), respectively, whereas Figures 7.2 and 7.4 are the graphs which are plotted using fitting factor for the same value of \( n \) and \( \varepsilon = 0.001 \) and \( \varepsilon = 0.0005 \), respectively. Similarly Figures 7.5 and 7.7...
are graphs without using fitting factor for Example 6.2 for $\varepsilon = 0.001$ and $\varepsilon = 0.0001$, respectively, whereas Figures 7.6 and 7.8 are graphs which are plotted using fitting factor for the same value of $n$ and $\varepsilon = 0.001$ and $\varepsilon = 0.0001$, respectively. It can be seen from Figures 7.1, 7.3, 7.5, and 7.7 that the exact and approximate solutions without using fitting factor deviate from each other in the boundary layer regions for smaller $\varepsilon$. To control these fluctuations, we used fitting-factor technique and the resulting behaviour of these two solutions can be seen from Figures 7.2, 7.4, 7.6, and 7.8. The similar observation can be made for the other examples also.
Finally, we would like to remark that we have replaced $\varepsilon$ by $\sigma(x, \varepsilon)$ in the normalized form and not in the original selfadjoint problem (i.e., problem (1.1)), with $a(x) \neq$ constant because in that case $\varepsilon$ is a multiple of both the second and first derivative terms which will cause implicit expressions whereas in normalized form, $\varepsilon$ is multiplied with the second derivative term only and hence, the fitting-factor technique on the normalized form can easily be implemented. This shows the importance of reducing the original selfadjoint problem to normal form.
Acknowledgement. The computations reported in this paper were done on Silicon Graphics Origin 200 (dual processor) Operating System (in Fortran 77 in double precision with 16 significant figures) at the Indian Institute of Technology Kanpur.
