We obtain a height estimate concerning to a compact spacelike hypersurface $\Sigma^n$ immersed with constant mean curvature $H$ in the anti-de Sitter space $\mathbb{H}^{n+1}$, when its boundary $\partial \Sigma$ is contained into an umbilical spacelike hypersurface of this spacetime which is isometric to the hyperbolic space $\mathbb{H}^n$. Our estimate depends only on the value of $H$ and on the geometry of $\partial \Sigma$. As applications of our estimate, we obtain a characterization of hyperbolic domains of $\mathbb{H}^{n+1}$ and nonexistence results in connection with such types of hypersurfaces.

1. Introduction

Interest in the study of spacelike hypersurfaces in Lorentzian manifolds has increased very much in recent years, from both the physical and mathematical points of view. For example, it was pointed out by J. Marsden and F. Tipler in [1] and S. Stumbles in [2] that spacelike hypersurfaces with constant mean curvature in arbitrary spacetimes play an important part in the relativity theory. They are convenient as initial hypersurfaces for the Cauchy problem in arbitrary spacetime and for studying the propagation of gravitational radiation. From a mathematical point of view, that interest is also motivated by the fact that these hypersurfaces exhibit nice Bernstein-type properties. Actually, E. Calabi in [3], for $n \leq 4$, and Cheng and Yau in [4], for arbitrary $n$, showed that the only complete immersed spacelike hypersurfaces of the $(n+1)$-dimensional Lorentz-Minkowski space $\mathbb{L}^{n+1}$ with zero mean curvature are the spacelike hyperplanes.

Related with the compact case, Alías and Malacarne in [5] showed that the only compact spacelike hypersurfaces having constant higher-order mean curvature and spherical boundary in $\mathbb{L}^{n+1}$ are the hyperplanar balls with zero higher-order mean curvature, and the hyperbolic caps with nonzero constant higher-order mean curvature (cf. [6] for the case of constant mean curvature and [7] for the case of constant scalar curvature; see also [8]
for the case of 2-dimensional surfaces in $\mathbb{L}^3$). Also considering the compact case, R. Lópezn obtained a sharp estimate for the height of compact spacelike surfaces $\Sigma^n$ immersed into the 3-dimensional Lorentz-Minkowski space $\mathbb{L}^3$ with constant mean curvature (cf. [9], Theorem 1). For the case of constant higher-order mean curvature, by applying the techniques used by D. Hoffman et al. in [10], the first author obtained another sharp height estimate for compact spacelike hypersurfaces immersed in the $(n + 1)$-dimensional Lorentz-Minkowski space $\mathbb{L}^{n+1}$ (cf. [11], Theorem 4.2).

Also recently, the first author obtained some geometric estimates concerning to a spacelike hypersurface immersed with some constant higher-order mean curvature in de Sitter space (cf. [12]), also, in a Lorentzian product space with Colares (cf. [13]) and in a conformally stationary Lorentz manifold with A. Caminha (cf. [14]). We note that, in each one of these papers, the authors have used their geometric estimates to study the existence of certain types of spacelike hypersurfaces in such spacetimes.

In [15] the first author and A. Caminha have studied complete vertical graphs of constant mean curvature in the hyperbolic and steady state spaces. Under appropriate restrictions on the values of the mean curvature and the growth of the height function, they obtained necessary conditions for the existence of such a graph. In the 2-dimensional case they applied their analytical framework to prove Bernstein-type results in each of these ambient spaces.

We note that Albujer and Alías have also recently considered in [16] complete spacelike hypersurfaces with constant mean curvature in the steady state space. They proved that if the hypersurface is bounded away from the infinity of the ambient space, then the mean curvature must be $H = 1$. In the 2-dimensional case they concluded that the only complete spacelike surfaces with constant mean curvature which are bounded away from the infinity are the totally umbilical flat surfaces. Moreover, considering the generalized Robertson-Walker spacetime model of the steady state space, they extended their results to a wider family of spacetimes.

In this paper we deal with a compact spacelike hypersurface $\Sigma^n$ immersed with constant mean curvature $H$ in the antide Sitter space $\mathbb{H}^{n+1}_1$, which is a particular model of Robertson-Walker spacetime given by $\mathbb{H}^{n+1}_1 = \mathbb{H}^n \times \mathbb{H}^{1}$, where $\mathbb{H}^n$ denotes the $n$-dimensional hyperbolic space (cf. Section 3). In this setting, by supposing its boundary $\partial \Sigma$ contained into some slice of $\mathbb{H}^{n+1}_1$, we obtain an estimate for its vertical height function $h$. We prove the following result (cf. Theorem 3.2):

Let $\varphi : \Sigma^n \to \mathbb{H}^{n+1}_1$ be a compact spacelike hypersurface whose boundary $\partial \Sigma$ is contained in some slice $\mathbb{H}^n_{t_0} = \{t_0\} \times \mathbb{H}^n$. Suppose that the mean curvature $H > 1$ is constant.

(i) If $-\pi/2 < t_0 \leq 0$ and $\Sigma^n$ is contained into the chronological past with respect to $\mathbb{H}^n_{t_0}$, then the height $h$ of $\Sigma^n$ satisfies

$$t_0 \geq h \geq t_0 - \frac{1}{H - 1} (C \cos t_0 - \cos h). \quad (1.1)$$

(ii) If $0 \leq t_0 < \pi/2$ and $\Sigma^n$ is contained into the chronological future with respect to $\mathbb{H}^n_{t_0}$, then the height $h$ of $\Sigma^n$ satisfies

$$t_0 \leq h \leq t_0 + \frac{1}{H - 1} (C \cos t_0 - \cos h). \quad (1.2)$$

Here $C = \max_{\Sigma} (\cosh \theta)$ and $\theta$ is the hyperbolic angle between the Gauss map $N$ of $\Sigma$ and $\partial_t$. 
Suitable formulae for the Laplacians of the height function and a support-like function naturally attached to a spacelike hypersurface $\Sigma'$ immersed in $\mathbb{H}^{n+1}$ constitute the analytical tools that we use to get our estimate (cf. Lemma 2.1).

It is important to point out that our estimate depends only on the value of the mean curvature and on the geometry of the boundary of the hypersurface. On the other hand, we recall that an integral curve of the unit time-like vector field $\partial_t$ is called a comoving observer and, when $p$ is a point of a spacelike hypersurface $\Sigma^n$ immersed into a Robertson-Walker spacetime $-\mathbb{R} \times_f M^n$, $\partial_t(p)$ is called an instantaneous comoving observer. In this setting, among the instantaneous observers at $p$, $\partial_t(p)$ and $N(p)$ appear naturally. From the orthogonal decomposition $N(p) = -\langle N, \partial_t \rangle_p \partial_t(p) + (\pi_M)_* N(p)$ where $\pi_M$ denotes the canonical projection from $-\mathbb{R} \times_f M^n$ onto the Riemannian fiber $M^n$, we have that $\cosh \theta(p)$ corresponds to the energy $e(p)$ that $\partial_t(p)$ measures for the normal observer $N(p)$. Furthermore, the speed $|v(p)|$ of the Newtonian velocity $v(p) := (1/e(p))(\pi_M)_* N(p)$ that $\partial_t(p)$ measures for $N(p)$ satisfies the equation $|v(p)|^2 = \tanh \theta(p)$. So, a physical consequence of the boundedness of the hyperbolic angle $\theta$ between the Gauss map $N$ of the spacelike hypersurface $\Sigma^n$ and $\partial_t$ is that the speed of the Newtonian velocity that the instantaneous comoving observer measures for the normal observer does not approach the speed of light 1 on $\Sigma^n$ (see [17], Sections 2.1 and 3.1, and [18]; see also [19], Chapter 12).

As an application of our height estimate, we obtain an characterization of hyperbolic domains of $\mathbb{H}^{n+1}$ (cf. Corollary 4.3). Furthermore, we establish nonexistence results in connection with such types of hypersurfaces (cf. Corollaries 4.4 and 4.5). For example, we prove the following.

There is no compact spacelike hypersurface $\varphi : \Sigma^n \to \mathbb{H}^{n+1}_1$, with constant mean curvature $H \geq 2$ and tangent to the slice $\mathbb{H}^n_0$ along its boundary.

Finally, we observe that an interesting feature of the four-dimensional anti-Sitter space $\mathbb{H}^4$ is that, as a cosmological model, this spacetime is a maximally symmetric universe with constant negative curvature, which is conformally related to half of the Einstein static universe. Consequently, $\mathbb{H}^4$ represents a (locally) unique solution to Einstein’s equation in the absence of any ordinary matter or gravitational radiation. In this setting, this spacetime may be thought of as a ground state of general relativity (cf. [20], Chapter 8; see also [21], Chapter 6, and [22], Chapter 14).

2. Preliminaries

In what follows, if $\overline{M}^{n+1}$ is a connected semi-Riemannian manifold with metric $\overline{g} = \langle \ , \ , \rangle$, we let $\mathfrak{X}(\overline{M})$ denote the ring of smooth functions $\phi : \overline{M}^{n+1} \to \mathbb{R}$ and $\mathfrak{X}(\overline{M})$ the algebra of smooth vector fields on $\overline{M}^{n+1}$. We also write $\nabla$ for the Levi-Civita connection of $\overline{M}^{n+1}$.

Let $M^n$ be a connected, $n$-dimensional ($n \geq 2$) oriented Riemannian manifold, $I$ a 1-dimensional manifold (either a circle or an open interval of $\mathbb{R}$), and $f : I \to \mathbb{R}$ a positive smooth function. In the product differentiable manifold $\overline{M}^{n+1} = I \times M^n$, let $\pi_I$ and $\pi_M$ denote the projections onto the factors $I$ and $M^n$, respectively.

A particular class of Lorentzian manifolds (spacetimes) is the one obtained by furnishing $\overline{M}^{n+1}$ with the metric

$$
(v, w)_p = -\langle (\pi_I)_* v, (\pi_I)_* w \rangle + (f \circ \pi_I)(p)(\langle (\pi_M)_* v, (\pi_M)_* w \rangle)
$$

(2.1)
for all $p \in M^{n+1}$ and all $v, w \in T_pM$. Such a space is called (following the terminology introduced in [23]) a Generalized Robertson-Walker (GRW) spacetime, and in what follows we shall write $\overline{M}^{n+1} = -I \times_f M^n$ to denote it. In particular, when $M^n$ has constant sectional curvature, then $-I \times_f M^n$ is classically called a Robertson-Walker (RW) spacetime (cf. [19]). It is not difficult to see that a GRW spacetime $-I \times_f M^n$ has constant sectional curvature $\kappa$ if, and only if, the Riemannian fiber $M^n$ has constant sectional curvature $\kappa$ (i.e., $-I \times_f M^n$ is in fact a RW spacetime) and the warping function $f$ satisfies the following differential equations:

$$
\frac{f''}{f} = \frac{f' \kappa}{f^2} + \kappa
$$

(see, for instance, [24], Corollary 9.107).

We recall that a tangent vector field $K$ on a spacetime $\overline{M}^{n+1}$ is said to be conformal if the Lie derivative with respect to $K$ of the metric $\langle , \rangle$ of $\overline{M}^{n+1}$ satisfies

$$
\mathcal{L}_K \langle , \rangle = 2\phi \langle , \rangle
$$

for a certain smooth function $\phi \in \mathcal{D}(\overline{M}^{n+1})$. Since $\mathcal{L}_K(X) = [K, X]$ for all $X \in \frak{x}(\overline{M})$, it follows from the tensorial character of $\mathcal{L}_K$ that $K \in \frak{x}(\overline{M})$ is conformal if and only if

$$
\left\langle \nabla_X K, Y \right\rangle + \left\langle X, \nabla_Y K \right\rangle = 2\phi \langle X, Y \rangle
$$

for all $X, Y \in \frak{x}(\overline{M})$. In particular, $K$ is a Killing vector field relatively to the metric $\langle , \rangle$ if and only if $\phi \equiv 0$.

We observe that when $\overline{M}^{n+1} = -I \times_f M^n$ is a GRW spacetime, the vector field

$$
K = f \partial_t = (f \circ \pi_I) \partial_t
$$

is conformal and closed (in the sense that its dual 1–form is closed), with conformal factor $\phi = f'$, where the prime denotes differentiation with respect to $t \in I$ (cf. [25]).

A smooth immersion $\psi : \Sigma^n \rightarrow \overline{M}^{n+1}$ of an $n$-dimensional connected manifold $\Sigma^n$ is said to be a \textit{spacelike hypersurface} if the induced metric via $\psi$ is a Riemannian metric on $\Sigma^n$, which, as usual, is also denoted for $\langle , \rangle$. In that case, since

$$
\partial_t = \left( \frac{\partial}{\partial t} \right)_{(t, x)} , \quad (t, x) \in -I \times_f M^n
$$

is a unitary time-like vector field globally defined on the ambient GRW spacetime, then there exists a unique time-like unitary normal field $N$ globally defined on the spacelike hypersurface $\Sigma^n$ which is in the same time-orientation as $\partial_t$, so that

$$
\langle N, \partial_t \rangle \leq -1 < 0 \quad \text{on} \; \Sigma^n.
$$
We will refer to that normal field $N$ as the future-pointing Gauss map of the spacelike hypersurface $\Sigma^n$. Its opposite will be referred as the past-pointing Gauss map of $\Sigma^n$.

In this setting, let $A : \mathcal{X}(\Sigma) \to \mathcal{X}(\Sigma)$ stand for the shape operator (or Weingarten endomorphism) of $\Sigma^n$ with respect to either the future or the past-pointing Gauss map $N$. It is well known that $A$ defines a self-adjoint linear operator on each tangent space $T_p\Sigma$, and its eigenvalues $\kappa_1(p), \ldots, \kappa_n(p)$ are the principal curvatures of $\Sigma^n$ at $p$. Associated to the shape operator $A$ there are $n$ algebraic invariants given by

$$S_r(p) = \sigma_r(\kappa_1(p), \ldots, \kappa_n(p)), \quad 1 \leq r \leq n,$$

where $\sigma_r : \mathbb{R}^n \to \mathbb{R}$ is the elementary symmetric function in $\mathbb{R}^n$ given by

$$\sigma_r(x_1, \ldots, x_n) = \sum_{i_1 < \cdots < i_r} x_{i_1} \cdots x_{i_r}. \quad (2.8)$$

Observe that the characteristic polynomial of $A$ can be written in terms of the $S_r$ as

$$\det(tI - A) = \sum_{r=0}^n (-1)^r S_r t^{n-r}, \quad (2.10)$$

where $S_0 = 1$ by definition. The $r$-mean curvature $H_r$ of the spacelike hypersurface $\Sigma^n$ is then defined by

$$\binom{n}{r} H_r = (-1)^r S_r(\kappa_1, \ldots, \kappa_n) = S_r(-\kappa_1, \ldots, -\kappa_n). \quad (2.11)$$

In particular, when $r = 1$,

$$H_1 = -\frac{1}{n} \sum_{i=1}^n \kappa_i = -\frac{1}{n} \text{tr}(A) = H \quad (2.12)$$

is the mean curvature of $\Sigma^n$, which is the main extrinsic curvature of the hypersurface. The choice of the sign $(-1)^r$ in our definition of $H_r$ is motivated by the fact that in that case the mean curvature vector is given by $\overrightarrow{H} = H N$. Therefore, $H(p) > 0$ at a point $p \in \Sigma^n$ if and only if $\overrightarrow{H}(p)$ is in the same time-orientation as $N(p)$ (in the sense that $\langle \overrightarrow{H}, N \rangle_p < 0$).

When $r = 2$, $H_2$ defines a geometric quantity which is related to the (intrinsic) scalar curvature $R$ of the hypersurface. For instance, when the ambient spacetime $\overline{M}^{n+1}$ has constant sectional curvature $\overline{\kappa}$, it follows from the Gauss equation that

$$R = n(n - 1)(\overline{\kappa} - H_2). \quad (2.13)$$
Moreover, in the case of a 2-dimensional surface, denoting by \( K_\Sigma \) the Gaussian curvature of the spacelike surface \( \psi : \Sigma^2 \to \overline{M}^3 \), we have that
\[
K_\Sigma = \kappa - H_2.
\] (2.14)

As before, let \( \overline{M}^{n+1} = -I \times fM^n \) be a GRW. For a fixed \( t_0 \in I \), we say that \( M^n_{t_0} = \{t_0\} \times M^n \) is a slice of \( \overline{M}^{n+1} \). It was proved by L.J. Alías et al. in [23] that each slice \( M^n_{t_0} \) is an umbilical spacelike hypersurface with constant r-mean curvature, equal to \( (f'(t_0)/f(t_0))^r \) with respect to \( \partial_t \) (see also Example 5.6 in [26]). Whenever we talk about the mean curvature of the slices of a GRW, we shall assume that it is computed with respect to \( \partial_t \). Also, if the (vertical) height function \( h : \Sigma^n \to I \) of \( \Sigma^n \), given by \( h = \pi_I \circ \psi \), is such that \( h \leq t_0 \) \( (h \geq t_0) \) for some \( t_0 \in I \), then we say that \( \Sigma^n \) is a spacelike hypersurface contained into the chronological past (chronological future) with respect to the slice \( M^n_{t_0} \).

To close this section, we present the analytical framework that we will use to obtain our estimates. The formulae collected in the following lemma are particular cases of ones obtained by L.J. Alías and A.G. Colares (cf. [27], Lemma 4.1 and Corollary 8.4).

**Lemma 2.1.** Let \( \psi : \Sigma^n \to -I \times fM^n \) be a spacelike hypersurface immersed into a GRW spacetime, with Gauss map \( N \) and denote for \( h = \pi_I \circ \psi \) the height function of \( \Sigma^n \). Then
\[
\Delta h = -(\ln f)'(h) \left( n + |\nabla h|^2 \right) - nH \langle N, \partial_t \rangle.
\] (2.15)

Moreover, by supposing \( \overline{M}^{n+1} \) an RW spacetime with Riemannian fiber \( M^n \) of constant sectional curvature \( \kappa \),
\[
\Delta (f(h)\langle N, \partial_t \rangle) = nf(h)\langle \nabla H, \partial_t \rangle + nH f'(h)
+ nf(h)\langle N, \partial_t \rangle \left( nH^2 - (n-1)H_2 \right)
+ (n-1)f(h)\langle N, \partial_t \rangle \left( \frac{\kappa}{f^2(h)} - (\ln f)'(h) \right) |\nabla h|^2.
\] (2.16)

**Remark 2.2.** For alternative proofs of the previous lemma, we suggest [11, 15, 18, 28].

### 3. Height Estimate for Spacelike Hypersurfaces in \( \mathbb{H}^{n+1}_1 \)

In what follows we consider a particular model of RW spacetime, the **anti-de Sitter space**, namely
\[
\mathbb{H}^{n+1}_1 = -\left( -\frac{\pi}{2}, \frac{\pi}{2} \right) \times \cos \mathbb{H}^n,
\] (3.1)

where \( \mathbb{H}^n \) denotes the \( n \)-dimensional hyperbolic space (see [29], Chapter 5).
Remark 3.1. The spacetime \( \mathbb{H}^{n+1}_1 \) can also be regarded as the hyperquadric
\[
\mathbb{H}^{n+1}_1 = \left\{ p \in \mathbb{R}^{n+2}_2; \langle p, p \rangle = -1 \right\},
\]
in the indefinite index two flat space \( \mathbb{R}^{n+2}_2 \). For any timelike unit vector \( a \in \mathbb{R}^{n+2}_2 \), we have that
\[
K(p) = a + \langle a, p \rangle p, \quad p \in \mathbb{H}^{n+1}_1,
\]
is timelike on the open set consisting of the points \( p \in \mathbb{H}^{n+1}_1 \) such that \( \langle a, p \rangle^2 < 1 \). This open set has two connect components and the distribution on \( \mathbb{H}^{n+1}_1 \) orthogonal to \( K \) provides a foliation \( \mathcal{F}(K) \) in this spacetime by means of the umbilical spacelike hypersurfaces \( \langle p, a \rangle = \tau, -1 < \tau < 1 \), which are isometric to two copies of hyperbolic spaces \( \mathbb{H}^n \) with constant sectional curvature \(-1/(1 + \tau^2)\). Consequently, each of these two components can be described as the Lorentz warped product \( -(-\pi/2, \pi/2) \times_{\cos \theta} \mathbb{H}^n \) (see [25], Example 3 and Proposition 1).

Now, we present our main result.

**Theorem 3.2.** (Height Estimate) Let \( \Sigma^n \to \mathbb{H}^{n+1}_1 \) be a compact spacelike hypersurface whose boundary \( \partial \Sigma \) is contained in some slice \( \mathbb{H}^{n+1}_1 = \{ t_0 \} \times \mathbb{H}^n \). Suppose that the mean curvature \( H > 1 \) is constant.

(i) If \(-\pi/2 < t_0 \leq 0 \) and \( \Sigma^n \) is contained into the chronological past with respect to \( \mathbb{H}^{n}_1 \), then the height \( h \) of \( \Sigma^n \) satisfies
\[
t_0 \geq h \geq t_0 - \frac{1}{H-1} (C \cos t_0 - \cos h).
\]

(ii) If \( 0 \leq t_0 < \pi/2 \) and \( \Sigma^n \) is contained into the chronological future with respect to \( \mathbb{H}^{n}_1 \), then the height \( h \) of \( \Sigma^n \) satisfies
\[
t_0 \leq h \leq t_0 + \frac{1}{H-1} (C \cos t_0 - \cos h).
\]

Here \( C = \max_{\partial \Sigma} (\cosh \theta) \) and \( \theta \) is the hyperbolic angle between the Gauss map \( N \) of \( \Sigma \) and \( \partial_t \).

**Proof.** Suppose initially that \(-\pi/2 < t_0 \leq 0 \) and \( \Sigma^n \) is contained into the chronological past with respect to \( \mathbb{H}^{n}_1 \). From Lemma 2.1, we have
\[
\Delta h = \tan h (n + |\nabla h|^2) - n H \langle N, \partial_t \rangle.
\]

Then, since \( h \leq t_0 \leq 0 \), as a consequence of the maximum principle we must have \( \Delta h(p) \geq 0 \) for some point \( p \in \Sigma^n \). Consequently, taking into account that we are supposing \( H > 1 \), we conclude that the Gauss map \( N \) of \( \Sigma^n \) is future-pointing, that is,
\[
\langle N, \partial_t \rangle \leq -1
\]
on $\Sigma^n$. Now, in order to get our estimate, we define on $\Sigma^n$ the function

$$\varphi = c(h - t_0) - \cos h(N, \partial_t),$$

where $c$ is a negative constant to be determined. By computing the Laplacian of $\varphi$ with the aid of Lemma 2.1, we get

$$\Delta \varphi = C \tan h (n + |\nabla h|^2) - c \ nH(N, \partial_t) + nH \sin h$$

$$- \cos h(N, \partial_t) \left( n^2 H^2 - n(n - 1)H_2 \right),$$

where we have used the fact that the Riemannian fiber of $\mathbb{H}^{n+1}$ has constant sectional curvature $\kappa = -1$. Moreover, again as a consequence of the maximum principle, if $\Delta \varphi \geq 0$, then

$$\varphi \leq \varphi|_{\partial \Sigma} = (-\langle N, \partial_t \rangle|_{\partial \Sigma}) \cos t_0 = (\cosh \theta|_{\partial \Sigma}) \cos t_0$$

$$\leq \max_{\partial \Sigma} (\cosh \theta) \cos t_0 = C \cos t_0$$

on $\Sigma^n$, and

$$0 \geq t_0 \geq h \geq t_0 + \frac{1}{c} (C \cos t_0 - \cos h).$$

We claim that it is possible to choose $c$ such that $\Delta \varphi \geq 0$. In fact, for all constant $c < 0$, it yields

$$C \tan h (n + |\nabla h|^2) \geq 0.$$

Putting this together with the Cauchy-Schwarz inequality $H^2 - H_2 \geq 0$ into the above expression of $\Delta \varphi$, we obtain

$$\Delta \varphi \geq nH(-\langle N, \partial_t \rangle(H \cos h + c) - 1).$$

Thus, since the Gauss map $N$ of $\Sigma^n$ is future-pointing, by taking

$$c = 1 - H$$

(3.11)
we get that $\Delta \varphi \geq 0$. Therefore,

$$t_0 \geq h \geq t_0 - \frac{1}{H-1}(C \cos t_0 - \cos h). \quad (3.15)$$

Now, suppose that $0 \leq t_0 < \pi/2$ and that $\Sigma$ is contained into the chronological future with respect to $\mathbb{H}^n_h$. In this case (again as a consequence of the maximum principle applied to the height function $h$), we have that Gauss map $N$ of $\Sigma^n$ is past-pointing, that is,

$$\langle N, \partial_t \rangle \geq 1 \quad (3.16)$$
on $\Sigma^n$. Thus, we define on $\Sigma$ the function

$$\varphi = c(h - t_0) + \cos h \langle N, \partial_t \rangle, \quad (3.17)$$

where $c$ is a positive constant to be determined. From this point, by taking

$$c = H - 1 \quad (3.18)$$

and working in a similar way as in the previous case we conclude that

$$t_0 \leq h \leq t_0 + \frac{1}{H-1}(C \cos t_0 - \cos h). \quad (3.19)$$

Remark 3.3. Related to our previous theorem, it is important to observe the following facts.

(a) We note that, while in the Riemannian case (from the Cauchy-Schwarz inequality) the support function $\langle N, \partial_t \rangle$ of $\Sigma^n$ is always bounded, in the Lorentzian setting this boundedness occurs in a natural manner only when the spacelike hypersurface $\Sigma^n$ is compact. Consequently, in this last case, it is plausible that for an estimate of the vertical height $h$ must appear a term that depends on the geometry of the spacelike hypersurface. For example, the estimate of López for the height of a compact spacelike surface $\Sigma^2$ immersed with constant mean curvature into the 3-dimensional Lorentz-Minkowski space $\mathbb{L}^3$ and whose boundary $\partial \Sigma$ is included in a plane $\Pi$ depends on the value of the mean curvature and on the area of the region of $\Sigma^2$ above the plane $\Pi$ (cf. [9], Theorem 1). On the other hand, from Theorem 3.2, we see that our estimate depends on the value of the mean curvature and on the geometry of the boundary $\partial \Sigma$.

(b) Geometrically, observing that $|\langle N, \partial_t \rangle| = \cosh \theta$, we see that the boundedness of the hyperbolic angle $\theta$ means that (at each point $p \in \Sigma^n$) the normal direction $N(p)$ remains far from the light cone corresponding to $\partial_t(p)$. So, a physical consequence of this fact is that the speed of the Newtonian velocity that the instantaneous comoving observer $\partial_t(p)$ measures for the normal observer $N(p)$ does not approach the speed of light on $\Sigma^n$ (see [17], Sections 2.1 and 3.1, and [18]; see also [19], Chapter 12).
4. HyperbolicDomains of $\mathbb{H}_1^{n+1}$

When a compact spacelike hypersurface $\psi: \Sigma^n \to \mathbb{H}_1^{n+1}$ is entirely contained into some slice $\mathbb{H}_t^0 = \{ t_0 \} \times \mathbb{H}^n$, it is called a hyperbolic domain of $\mathbb{H}_1^{n+1}$. As applications of Theorem 3.2, we obtain the following results.

**Proposition 4.1.** Let $\psi: \Sigma^n \to \mathbb{H}_1^{n+1}$ be a compact spacelike hypersurface whose boundary $\partial \Sigma$ is contained in some slice $\mathbb{H}_t^0$. Suppose that $\Sigma^n$ is not a hyperbolic domain, i.e., mean curvature $H > 1$ is constant, and that one of the following conditions is satisfied.

(i) $-\pi/2 < t_0 \leq 0$ and $\Sigma^n$ is contained into the chronological past with respect to $\mathbb{H}_t^0$.

(ii) $0 \leq t_0 < \pi/2$ and $\Sigma^n$ is contained into the chronological future with respect to $\mathbb{H}_t^0$.

Then

$$H \leq 1 + \frac{C \cos t_0 - \cos h^*}{|h^* - t_0|},$$

where $C = \max_{\partial \Sigma}(\cosh \theta)$, $\theta$ is the hyperbolic angle between the Gauss map $N$ of $\Sigma$ and $\partial t$, and $h^* = \max_{\Sigma^n} h$.

In what follows, we say that $\Sigma^n$ is tangent to $\mathbb{H}_t^0$ along its boundary if $\partial \Sigma$ is contained into $\mathbb{H}_t^0$, and the restriction of the Gauss map $N$ of $\Sigma^n$ to $\partial \Sigma$ is equal to $(\partial t)_{t=t_0}$ or $- (\partial t)_{t=t_0}$ (that is, the hyperbolic angle between $N$ and $\partial t$ is identically zero along $\partial \Sigma$).

**Proposition 4.2.** Let $\psi: \Sigma^n \to \mathbb{H}_1^{n+1}$ be a compact spacelike hypersurface, which is tangent to some slice $\mathbb{H}_t^0$ along its boundary. Suppose that $\Sigma^n$ is not a hyperbolic domain, that its mean curvature $H > 1$ is constant and that one of the following conditions is satisfied.

(i) $-\pi/2 < t_0 \leq 0$ and $\Sigma^n$ is contained into the chronological past with respect to $\mathbb{H}^n_t$.

(ii) $0 \leq t_0 < \pi/2$ and $\Sigma^n$ is contained into the chronological future with respect to $\mathbb{H}^n_t$.

Then

$$1 < H \leq 1 + |\sin t_0| < 2.$$  

**Proof.** Initially, we observe, from Proposition 4.1 and from our assumption, that $\Sigma^n$ is tangent to $\mathbb{H}_t^0$ along its boundary:

$$H \leq 1 + \frac{\cos t_0 - \cos h(p)}{|h(p) - t_0|}$$

for all $p \in \Sigma^n$ such that $h(p) \neq t_0$. Therefore, taking in the previous inequality the limit $h(p) \to t_0$, we conclude that

$$H \leq 1 + |\sin t_0| < 2.$$
As a consequence of the previous result, we get the following characterization of hyperbolic domains of $\mathbb{H}^{n+1}$.

**Corollary 4.3.** Let $\varphi : \Sigma^n \to \mathbb{H}^{n+1}$ be a compact spacelike hypersurface, which is tangent to some slice $\mathbb{H}^n_{t_0}$ along its boundary. Suppose that one of the following conditions is satisfied.

(i) $\pi / 2 < t_0 \leq -\arctan 2$ and $\Sigma^n$ is contained into the chronological past with respect to $\mathbb{H}^n_{t_0}$.

(ii) $\arctan 2 \leq t_0 < \pi / 2$ and $\Sigma^n$ is contained into the chronological future with respect to $\mathbb{H}^n_{t_0}$.

If its mean curvature $H \geq 2$ is constant, then $\Sigma^n$ is a hyperbolic domain.

Finally, we obtain the following nonexistence results.

**Corollary 4.4.** There is no compact spacelike hypersurface $\varphi : \Sigma^n \to \mathbb{H}^{n+1}$ tangent to some slice $\mathbb{H}^n_{t_0}$ along its boundary, with constant mean curvature $H \geq 2$ and satisfying one of the following conditions.

(i) $\Sigma^n$ is contained into the chronological past with respect to $\mathbb{H}^n_{t_0}$, with $-\arctan 2 < t_0 \leq 0$.

(ii) $\Sigma^n$ is contained into the chronological future with respect to $\mathbb{H}^n_{t_0}$, with $0 \leq t_0 < \arctan 2$.

**Corollary 4.5.** There is no compact spacelike hypersurface $\varphi : \Sigma^n \to \mathbb{H}^{n+1}$ with constant mean curvature $H \geq 2$ and tangent to the slice $\mathbb{H}^n_0$ along its boundary.
