Let N be a near ring. An additive mapping $f : N \rightarrow N$ is said to be a right generalized (resp., left generalized) derivation with associated derivation d on N if $f(xy) = f(x)y + xd(y)$ (resp., $f(xy) = d(x)y + xf(y)$) for all $x, y \in N$. A mapping $f : N \rightarrow N$ is said to be a generalized derivation with associated derivation d on N if f is both a right generalized and a left generalized derivation with associated derivation d on N . The purpose of the present paper is to prove some theorems in the setting of a semigroup ideal of a 3-prime near ring admitting a generalized derivation, thereby extending some known results on derivations.

1. Introduction

Throughout the paper, N denotes a zero-symmetric left near ring with multiplicative center Z , and for any pair of elements $x, y \in N$, $[x, y]$ denotes the commutator $xy - yx$, while the symbol (x, y) denotes the additive commutator $x + y - x - y$. A near ring N is called zero-symmetric if $0x = 0$, for all $x \in N$ (recall that left distributivity yields that $x0 = 0$). The near ring N is said to be 3-prime if $xNy = \{0\}$ for $x, y \in N$ implies that $x = 0$ or $y = 0$. A near ring N is called 2-torsion-free if $(N, +)$ has no element of order 2. A nonempty subset A of N is called a semigroup right (resp., semigroup left) ideal if $AN \subseteq A$ (resp., $NA \subseteq A$), and if A is both a semigroup right ideal and a semigroup left ideal, it is called a semigroup ideal. An additive mapping $d : N \rightarrow N$ is a derivation on N if $d(xy) = d(x)y + xd(y)$, for all $x, y \in N$. An additive mapping $f : N \rightarrow N$ is said to be a right (resp., left) generalized derivation with associated derivation d if $f(xy) = f(x)y + xd(y)$ (resp., $f(xy) = d(x)y + xf(y)$), for all $x, y \in N$, and f is said to be a generalized derivation with associated derivation d on N if it is both a right generalized derivation and a left generalized derivation on N with associated derivation d . (Note that this definition differs from the one given by Hvala in [1]; his generalized derivations are our right generalized derivations.) Every derivation on N is a generalized derivation.

In the case of rings, generalized derivations have received significant attention in recent years. We prove some theorems

in the setting of a semigroup ideal of a 3-prime near ring admitting a generalized derivation and thereby extend some known results [2, Theorem 2.1], [3, Theorem 3.1], [4, Theorem 3], and [5, Theorem 3.3].

2. Preliminary Results

We begin with several lemmas, most of which have been proved elsewhere.

Lemma 1 (see [3, Lemma 1.3]). *Let N be a 3-prime near ring and d be a nonzero derivation on N .*

- (i) *If U is a nonzero semigroup right ideal or a nonzero semigroup left ideal of N , then $d(U) \neq \{0\}$.*
- (ii) *If U is a nonzero semigroup right ideal of N and x is an element of N which centralizes U , then $x \in Z$.*

Lemma 2 (see [3, Lemma 1.2]). *Let N be a 3-prime near ring.*

- (i) *If $z \in Z \setminus \{0\}$, then z is not a zero divisor.*
- (ii) *If $Z \setminus \{0\}$ contains an element z for which $z + z \in Z$, then $(N, +)$ is abelian.*
- (iii) *If $z \in Z \setminus \{0\}$ and x is an element of N such that $xz \in Z$, then $x \in Z$.*

Lemma 3 (see [3, Lemmas 1.3 and 1.4]). *Let N be a 3-prime near ring and U be a nonzero semigroup ideal of N . Let d be a nonzero derivation on N .*

- (i) *If $x, y \in N$ and $xUy = \{0\}$, then $x = 0$ or $y = 0$.*
- (ii) *If $x \in N$ and $xU = \{0\}$ or $Ux = \{0\}$, then $x = 0$.*
- (iii) *If $x \in N$ and $d(U)x = \{0\}$ or $xd(U) = \{0\}$, then $x = 0$.*

Lemma 4 (see [3, Lemma 1.5]). *If N is a 3-prime near ring and Z contains a nonzero semigroup left ideal or a semigroup right ideal, then N is a commutative ring.*

Lemma 5. *If f is a generalized derivation on N with associated derivation d , then $(d(x)y + xf(y))z = d(x)yz + xf(y)z$, for all $x, y, z \in N$.*

Proof. We prove only (ii), since (i) is proved in [2]. For all $x, y, z \in N$ we have $f((xy)z) = f(xy)z + xyd(z) = (d(x)y + xf(y))z + xyd(z)$ and $f(x(yz)) = d(x)yz + xf(yz) = d(x)yz + xf(f(y)z + yd(z)) = d(x)yz + xf(f(y)z) + xyd(z)$. Comparing the two expressions for $f(xyz)$ gives (ii). $\square$

Lemma 6. *Let N be a 3-prime near ring and f a generalized derivation with associated derivation d .*

- (i) $f(x)y + xd(y) = xd(y) + f(x)y$ for all $x, y \in N$.
- (ii) $d(x)y + xf(y) = xf(y) + d(x)y$ for all $x, y \in N$.

Proof. (i) $f(x(y + y)) = f(x)(y + y) + xd(y + y) = f(x)y + f(x)y + xd(y) + xd(y)$, and $f(xy + xy) = f(x)y + xd(y) + f(x)y + xd(y)$. Comparing these two equations gives the desired result.

(ii) Again, calculate $f(x(y + y))$ and $f(xy + xy)$ and compare. $\square$

Lemma 7. *Let N be a 3-prime near ring and f a generalized derivation with associated derivation d . Then $f(Z) \subseteq Z$.*

Proof. Let $z \in Z$ and $x \in N$. Then $f(zx) = f(xz)$; that is, $f(z)x + zd(x) = d(x)z + xf(z)$. Applying Lemma 6(i), we get $zd(x) + f(z)x = d(x)z + xf(z)$. It follows that $f(z)x = xf(z)$ for all $x \in N$, so $f(z) \in Z$. $\square$

Lemma 8. *Let N be a 3-prime near ring and U a nonzero semigroup ideal of N . If f is a nonzero right generalized derivation of N with associated derivation d , then $f(U) \neq \{0\}$.*

Proof. Suppose $f(U) = \{0\}$. Then $f(ux) = f(u)x + ud(x) = 0 = ud(x)$ for all $u \in U$ and $x \in N$, and it follows by Lemma 3(ii) that $d = 0$. Therefore $f(xu) = f(x)u = 0$ for all $u \in U$ and $x \in N$, and another appeal to Lemma 3(ii) gives $f = 0$, which is a contradiction. $\square$

Lemma 9 (see [2, Theorem 2.1]). *Let N be a 3-prime near ring with a nonzero right generalized derivation f with associated derivation d . If $f(N) \subseteq Z$ then $(N, +)$ is abelian. Moreover, if N is 2-torsion-free, then N is a commutative ring.*

Lemma 10 (see [2, Theorem 4.1]). *Let N be a 2-torsion-free 3-prime near ring and f a nonzero generalized derivation on*

N with associated derivation d . If $[f(N), f(N)] = \{0\}$, then N is a commutative ring.

3. Main Results

The theorems that we prove in this section extend the results proved in [2, Theorems 2.1 and 3.1], [3, Theorems 2.1, 3.1, and 3.3], and [5, Theorem 3.3].

Theorem 11. *Let N be a 3-prime near ring and U be a nonzero semigroup ideal of N . Let f be a nonzero right generalized derivation with associated derivation d . If $f(U) \subseteq Z$, then $(N, +)$ is abelian. Moreover, if N is 2-torsion-free, then N is a commutative ring.*

Proof. We begin by showing that $(N, +)$ is abelian, which by Lemma 2(ii) is accomplished by producing $z \in Z \setminus \{0\}$ such that $z + z \in Z$. Let a be an element of U such that $f(a) \neq 0$. Then for all $x \in N$, $ax \in U$ and $ax + ax = a(x + x) \in U$, so that $f(ax) \in Z$ and $f(ax) + f(ax) \in Z$; hence we need only to show that there exists $x \in N$ such that $f(ax) \neq 0$. Suppose that this is not the case, so that $f((ax)a) = 0 = f(ax)a + axd(a) = axd(a)$, for all $x \in N$. By Lemma 3(i) either $a = 0$ or $d(a) = 0$.

If $d(a) = 0$, then $f(xa) = f(x)a + xd(a)$; that is, $f(xa) = f(x)a \in Z$, for all $x \in N$. Thus $[f(u)a, y] = 0$, for all $y \in N$, and $u \in U$. This implies that $f(u)[a, y] = 0$, for all $u \in U$ and $y \in N$ and Lemma 2(i) gives $a \in Z$. Thus $0 = f(ax) = f(xa) = f(x)a$, for all $x \in N$. Replacing x by $u \in U$, we have $f(U)a = 0$, and by Lemmas 2(i) and 8, we get that $a = 0$. Thus, we have a contradiction.

To complete the proof, we show that if N is 2-torsion-free, then N is commutative.

Consider first the case $d = 0$. This implies that $f(ux) = f(u)x \in Z$ for all $u \in U$ and $x \in N$. By Lemma 8, we have $u \in U$ such that $f(u) \in Z \setminus \{0\}$, so N is commutative by Lemma 2(iii).

Now consider the case $d \neq 0$. Let $c \in Z \setminus \{0\}$. This implies that if $x \in U$, $f(xc) = f(x)c + xd(c) \in Z$. Thus $(f(x)c + xd(c))y = y(f(x)c + xd(c))$ for all $x, y \in U$ and $c \in Z$. Therefore by Lemma 5(i), $f(x)cy + xd(c)y = yf(x)c + yxd(c)$ for all $x, y \in U$ and $c \in Z$. Since $d(c) \in Z$ and $f(x) \in Z$, we obtain $d(c)[x, y] = 0$, for all $x, y \in U$ and $c \in Z$. Let $d(Z) \neq 0$. Choosing c such that $d(c) \neq 0$ and noting that $d(c)$ is not a zero divisor, we have $[x, y] = 0$ for all $x, y \in U$. By Lemma 1(ii), $U \subseteq Z$; hence N is commutative by Lemma 4.

The remaining case is $d \neq 0$ and $d(Z) = \{0\}$. Suppose we can show that $U \cap Z \neq \{0\}$. Taking $z \in (U \cap Z) \setminus \{0\}$ and $x \in N$, we have $f(xz) = f(x)z \in Z$; therefore $f(N) \subseteq Z$ by Lemma 2(iii) and N is commutative by Lemma 9.

Assume, then, that $U \cap Z = \{0\}$. For each $u \in U$, $f(u^2) = f(u)u + ud(u) = u(f(u) + d(u)) \in U \cap Z$, so $f(u^2) = 0$. Thus, for all $u \in U$ and $x \in N$, $f(u^2x) = f(u^2)x + u^2d(x) = u^2d(x) \in U \cap Z$, so $u^2d(x) = 0$, and by Lemma 3(iii) $u^2 = 0$. Since $f(xu) = f(x)u + xd(u) \in Z$ for all $u \in U$ and $x \in N$, we have $(f(x)u + xd(u))u = u(f(x)u + xd(u))$, and right multiplying by u gives $uxd(u)u = 0$. Consequently $d(u)uNd(u)u = \{0\}$, so that $d(u)u = 0$ for all $u \in U$. Since $u^2 = 0$, $d(u^2) = d(u)u + ud(u) = 0$ for all $u \in U$, so

$f(u)u = 0$ for all $u \in U$. But by Lemma 8, there exists $u_0 \in U$ for which $f(u_0) \neq 0$; and since $f(u_0) \in Z$, we get $u_0 = 0$ —a contradiction. Therefore $U \cap Z \neq \{0\}$ as required. $\square$

Theorem 12. Let N be a 3-prime near ring with a nonzero generalized derivation f with associated nonzero derivation d . Let U be a nonzero semigroup ideal of N . If $[f(U), f(U)] = 0$, then $(N, +)$ is abelian.

Proof. Assume that $x \in N$ is such that $[x, f(U)] = [x + x, f(U)] = 0$. For all $u, v \in U$ such that $u + v \in U$, $[x + x, f(u + v)] = 0$.

This implies that

$$\begin{aligned}
 (x + x) f(u + v) &= f(u + v)(x + x), \\
 (x + x) f(u) + (x + x) f(v) \\
 &= f(u + v)x + f(u + v)x, \\
 f(u)(x + x) + f(v)(x + x) \\
 &= xf(u + v) + xf(u + v), \\
 f(u)x + f(u)x + f(v)x + f(v)x \quad (1) \\
 &= xf(u) + xf(v) + xf(u) + xf(v), \\
 xf(u) + xf(u) + xf(v) + xf(v) \\
 &= xf(u) + xf(v) + xf(u) + xf(v), \\
 x(f(u) + f(v) - f(u) - f(v)) &= 0, \\
 xf(u + v - u - v) &= 0.
 \end{aligned}$$

This equation may be restated as $xf(c) = 0$, where $c = (u, v)$.

Let $a, b \in U$. Then $ab \in U$ and $ab + ab = a(b + b) \in U$, so $[f(ab), f(U)] = \{0\} = [f(ab) + f(ab), f(U)]$, and by the argument in the previous paragraph, $f(ab)f(c) = 0$. We now have $f(U^2)f(u, v) = 0$ for all $u, v \in U$ such that $u + v \in U$. Taking $w \in U^2$ and $x \in N$, we get $f(xw)f((u, v)) = (d(x)w + xf(w))f((u, v)) = 0 = d(x)wf((u, v))$, and since U^2 is a nonzero semigroup ideal by Lemma 3(ii) and $d \neq 0$, Lemma 3(i) gives

$$f((u, v)) = 0 \quad \forall u, v \in U \text{ such that } u + v \in U. \quad (2)$$

Take $u = ry$ and $v = rz$, where $r \in U$ and $y, z \in N$, so that $u + v = ry + rz = r(y + z) \in U$. By (2) we have

$$f((ry, rz)) = f(r(y, z)) = 0 \quad \forall r \in U, y, z \in N. \quad (3)$$

Replacing r by rw , $w \in U$, we obtain $f(r(wy, wz)) = 0 = d(r)(w(y, z)) + rf((wy, wz))$; so by (3) $d(r)U(y, z) = 0$ for all $r \in U$ and $y, z \in N$. It follows immediately by Lemmas 1(i) and 3(i) that $(y, z) = 0$ for all $y, z \in N$; that is, $(N, +)$ is abelian. $\square$

Theorem 13. Let N be a 2-torsion-free 3-prime near ring and U be a nonzero semigroup ideal of N . If f is a nonzero generalized derivation with associated derivation d such that $[f(U), f(U)] = 0$, then N is a commutative ring if it satisfies

one of the following: (i) $d(Z) \neq \{0\}$; (ii) $U \cap Z \neq \{0\}$; (iii) $d = 0$ and $f(Z) \neq \{0\}$.

Proof. (i) Let $a \in N$ centralizes $f(U)$, and let $z \in Z$ such that $d(z) \neq 0$. Then a centralizes $f(uz)$ for all $u \in U$, so that $a(f(u)z + ud(z)) = (f(u)z + ud(z))a$ and $aud(z) = ud(z)a$. Since $d(z) \in Z \setminus \{0\}$, $d(z)[a, u] = 0 = [a, u]$ for all $u \in U$. Therefore a centralizes U , and by Lemma 1(ii), $a \in Z$. Since $f(U)$ centralizes $f(U)$, $f(U) \subseteq Z$ and our result follows by Theorem 11.

(ii) We may assume $d(Z) = \{0\}$. Let $z \in (U \cap Z) \setminus \{0\}$. Then for all $x, y \in N$, $f(xz) = f(x)z$ and $f(yz) = f(y)z$ commute; hence $z^2[f(x), f(y)] = 0 = [f(x), f(y)]$. Our result now follows from Lemma 10.

(iii) Let $u, v \in U$ and $z \in Z$ such that $f(z) \neq 0$. Then $[f(zu), f(u)] = 0 = [f(z)u, f(v)]$, and since $f(z) \in Z \setminus \{0\}$, $f(z)[u, f(u)] = 0 = [u, f(v)]$. Thus $f(U)$ centralizes U , and by Lemma 1(ii), $f(U) \subseteq Z$. Our result now follows by Theorem 11. $\square$

We have already observed that if f is a generalized derivation with $d = 0$, then $f(x)y = xf(y)$ for all $x, y \in N$. For 3-prime near rings, we have the following converse.

Theorem 14. Let N be a 3-prime near ring and U be a nonzero semigroup ideal of N . If f is a nonzero right generalized derivation of N with associated derivation d and $f(x)y = xf(y)$, for all $x, y \in U$, then $d = 0$.

Proof. We are given that $f(x)y = xf(y)$ for all $x, y \in U$. Substituting yz for y , we get $f(x)yz = xf(yz) = x(f(y)z + yd(z))$ for all $x, y, z \in U$. It follows that $xyd(z) = 0$ for all $x, y, z \in U$; that is, $xUd(z) = \{0\}$ for all $x, z \in U$. By Lemma 3(i), $d(U) = 0$, and hence $d = 0$ by Lemma 1(i). $\square$

4. Generalized Derivations Acting as a Homomorphism or an Antihomomorphism

In [4], Bell and Kappe proved that if R is a semiprime ring and d is a derivation on R which is either an endomorphism or an antiendomorphism on R , then $d = 0$. Of course, derivations which are not endomorphisms or antiendomorphisms on R may behave as such on certain subsets of R ; for example, any derivation d behaves as the zero endomorphism on the subring C consisting of all constants (i.e., the elements x for which $d(x) = 0$). In fact in a semiprime ring R , d may behave as an endomorphism on a proper ideal of R . However as noted in [4], the behaviour of d is somewhat restricted in the case of a prime ring. Recently the authors in [6] considered (θ, ϕ) -derivation d acting as a homomorphism or an antihomomorphism on a nonzero Lie ideal of a prime ring and concluded that $d = 0$. In this section we establish similar results in the setting of a semigroup ideal of a 3-prime near ring admitting a generalized derivation.

Theorem 15. Let N be a 3-prime near ring and U be a nonzero semigroup ideal of N . Let f be a nonzero generalized derivation on N with associated derivation d . If f acts as a

homomorphism on U , then f is the identity map on N and $d = 0$.

Proof. By the hypothesis

$$f(xy) = d(x)y + xf(y) = f(x)f(y) \quad \forall x, y \in U. \quad (4)$$

Replacing y by yz in the above relation, we get

$$f(xyz) = d(x)yz + xf(yz) \quad \forall x, y, z \in U, \quad (5)$$

or

$$f(xy)f(z) = d(x)yz + x(d(y)z + yf(z)) \quad \forall x, y, z \in U. \quad (6)$$

This implies that

$$(d(x)y + xf(y))f(z) = d(x)yz + xd(y)z + xyf(z) \quad \forall x, y, z \in U. \quad (7)$$

Using Lemma 5(ii), we get

$$\begin{aligned} d(x)yf(z) + xf(y)f(z) \\ = d(x)yz + xd(y)z + xyf(z) \quad \forall x, y, z \in U, \end{aligned} \quad (8)$$

or

$$\begin{aligned} d(x)yf(z) + xf(yz) \\ = d(x)yz + xd(y)z + xyf(z) \quad \forall x, y, z \in U. \end{aligned} \quad (9)$$

This implies that

$$\begin{aligned} d(x)yf(z) + xd(y)z + xyf(z) \\ = d(x)yz + xd(y)z + xyf(z) \quad \forall x, y, z \in U. \end{aligned} \quad (10)$$

That is,

$$d(x)yf(z) = d(x)yz \quad \forall x, y, z \in U. \quad (11)$$

Therefore

$$d(x)y(f(z) - z) = 0 \quad \forall x, y, z \in U, \quad (12)$$

which implies that

$$d(x)U(f(z) - z) = \{0\} \quad \forall x, z \in U. \quad (13)$$

It follows by Lemma 3(i) that either $d(U) = 0$ or $f(z) = z$ for all $z \in U$.

In fact, as we now show, both of these conditions hold.

Suppose that $f(u) = u$ for all $u \in U$. Then for all $u \in U$ and $x \in N$, $f(xu) = xu = d(x)u + xf(u) = d(x)u + xu$; hence $d(x)U = \{0\}$ for all $x \in N$, and thus $d = 0$.

On the other hand, suppose that $d(U) = \{0\}$, so that $d = 0$. Then for all $x, y \in U$, $f(xy) = f(x)y = f(x)f(y)$, so that $f(x)(y - f(y)) = 0$. Replacing y by zy , $z \in N$, and noting

that $f(zy) = zf(y)$, we see that $f(x)N(y - f(y)) = \{0\}$ for all $x, y \in U$. Therefore, $f(U) = \{0\}$ or f is the identity on U . But $f(U) = \{0\}$ contradicts Lemma 8, so f is the identity on U .

We now know that f is the identity on U and $f(xy) = xf(y)$ for all $x, y \in N$. Consequently, $f(ux) = ux = uf(x)$ for all $u \in U$ and $x \in N$, so that $U(x - f(x)) = \{0\}$ for all $x \in N$. It follows that f is the identity on N . $\square$

Theorem 16. Let N be a 3-prime near ring and U be a nonzero semigroup ideal of N . If f is a nonzero generalized derivation on N with associated derivation d . If f acts as an antihomomorphism on U , then $d = 0$, f is the identity map on N , and N is a commutative ring.

Proof. We begin by showing that $d = 0$ if and only if f is the identity map on N .

Clearly if f is the identity map on N , $xd(y) = 0$ for all $x, y \in N$, and hence $d = 0$.

Conversely, assume that $d = 0$, in which case $f(xy) = f(x)y = xf(y)$ for all $x, y \in N$. It follows that for any $x, y, z \in U$,

$$\begin{aligned} f(yxz) &= f(z)f(yx) = f(z)yf(x) \\ &= f(zy)f(x) = zf(y)f(x) = zf(xy). \end{aligned} \quad (14)$$

On the other hand,

$$\begin{aligned} f(yxz) &= f(xz)f(y) = f(x)zf(y) = f(x)f(zy) \\ &= f(x)f(y)f(z) = f(yx)f(z) = f(y)xf(z) \\ &= f(y)f(xz) = f(y)f(x)z = f(xy)z. \end{aligned} \quad (15)$$

Comparing (14) and (15) shows that $f(U^2)$ centralizes U , so that $f(U^2) \subseteq Z$ by Lemma 1(ii).

Now U^2 is a nonzero semigroup ideal by Lemma 3(ii); hence $f(U^2) \neq 0$ by Lemma 8. Choosing $x, y \in U$ such that $f(xy) \neq 0$, we see that for any $z \in U$, $f(xy)z = f(xyz) = f(yz)f(x) = f(y)zf(x) = f(y)f(zx) = f(y)f(x)f(z) = f(xy)f(z)$, and hence $f(xy)(z - f(z)) = 0$. Since $f(xy) \in Z \setminus \{0\}$, we conclude that $f(z) = z$ for all $z \in U$, and it follows easily that f is the identity map on N .

We note now that if the identity map on N acts as an antihomomorphism on U , then U is commutative, so that by Lemmas 1(ii) and 4 N is a commutative ring.

To complete the proof of our theorem, we need only to argue that $d = 0$. By our antihomomorphism hypothesis

$$f(xy) = d(x)y + xf(y) = f(y)f(x) \quad \forall x, y \in U. \quad (16)$$

Replacing y by xy in the above relation, we get

$$f(xy)f(x) = f(xxy) = d(x)xy + xf(xy) \quad \forall x, y \in U. \quad (17)$$

This implies that

$$\begin{aligned} (d(x)y + xf(y))f(x) \\ = d(x)xy + xf(y)f(x) \quad \forall x, y \in U. \end{aligned} \quad (18)$$

Using Lemma 5(ii), we get

$$\begin{aligned} d(x) y f(x) + x f(y) f(x) \\ = d(x) xy + x f(y) f(x) \quad \forall x, y \in U. \end{aligned} \quad (19)$$

Thus

$$d(x) y f(x) = d(x) xy \quad \forall x, y \in U. \quad (20)$$

Replacing y by yr in (20) and using (20), we get

$$\begin{aligned} d(x) y r f(x) = d(x) x y r, \text{ and so } d(x) y [r, f(x)] = 0 \\ \forall x, y \in U, r \in N. \end{aligned} \quad (21)$$

Application of Lemma 3(i) yields that for each $x \in U$ either $d(x) = 0$ or $[r, f(x)] = 0$; that is $d(x) = 0$ or $f(x) \in Z$.

Suppose that there exists $w \in U$ such that $f(w) \in Z \setminus \{0\}$. Then for all $v \in U$ such that $d(v) = 0$, $f(wv) = f(w)v = f(v)f(w) = f(w)f(v)$, and hence $f(w)(v - f(v)) = 0 = v - f(v)$. Now consider arbitrary $x, y \in U$. If one of $f(x), f(y)$ is in Z , then $f(xy) = f(x)f(y)$. If $d(x) = 0 = d(y)$, then $d(xy) = d(x)y + xd(y) = 0$, so $f(xy) = xy = f(x)f(y)$. Therefore $f(xy) = f(x)f(y)$ for all $x, y \in U$, and by Theorem 15, f is the identity map on N , and therefore $d = 0$.

The remaining possibility is that for each $x \in U$, either $d(x) = 0$ or $f(x) = 0$. Let $u \in U \setminus \{0\}$, and let $U_1 = uN$. Then U_1 is a nonzero semigroup right ideal contained in U and U_1 is an additive subgroup of N . The sets $\{x \in U_1 | d(x) = 0\}$ and $\{x \in U_1 | f(x) = 0\}$ are additive subgroups of U_1 with union equal to U_1 , so $d(U_1) = \{0\}$ or $f(U_1) = \{0\}$. If $d(U_1) = \{0\}$, then $d = 0$ by Lemma 1(i). Suppose, then, that $f(U_1) = \{0\}$. Then for arbitrary $x, y \in N$ $f(uxy) = f(ux)y + uxd(y) = 0 = uxd(y)$, so $uNd(y) = \{0\}$, and again $d = 0$. This completes the proof. $\square$

Acknowledgments

A. Ali and P. Miyan gratefully acknowledge the support received by the University Grants Commission, India Grant F. no. 33-106 (2008) and Council of Scientific and Industrial Research, India Grant F. no. 9/112 (0475) 2 K12-EMR-I. Let $z \in Z$ and $x \in N$. Then $f(zx) = f(xz)$; that is, $f(z)x + zd(x) = d(x)z + xf(z)$.
