Abstract

Double Laplace transform method is applied to find exact solutions of linear/nonlinear space-time fractional telegraph equations in terms of Mittag-Leffler functions subject to initial and boundary conditions. Furthermore, we give illustrative examples to demonstrate the efficiency of the method.

1. Introduction

The telegraph equation developed by Oliver Heaviside in 1880 is widely used in Science and Engineering. Its applications arise in signal analysis for transmission and propagation of electrical signals and also modelling reaction diffusion.

In recent years, great interest has been developed in fractional differential equation because of its frequent appearance in fluid mechanics, mathematical biology, electrochemistry, and physics. A space-time fractional telegraph equation is obtained from the classical telegraph equation by replacing the time and space derivative terms by fractional derivatives.

In recent years, significant attention has been given by many authors towards the study of fractional telegraph equations by using single Laplace transform combined with variational iteration method, homotopy analysis method, and homotopy perturbation method. Khan et al. [15], Kumar et al. [16], and Prakash [17] applied a combination of single Laplace transform and homotopy perturbation method to obtain analytic and approximate solutions of the space-time fractional telegraph equations. Alawad et al. [18] used a combination of single Laplace transform and variational iteration method for finding exact solutions of space-time fractional telegraph equations. Kumar in [19] coupled single Laplace transform and homotopy analysis method for the solution of space-fractional telegraph equation.
To our knowledge, solving fractional partial differential equations using the double Laplace transform is still seen in very little proportionate or no work is available in the literature. So, the main objective of this paper is to find the exact solutions of homogeneous and nonhomogeneous space-time fractional telegraph equations in terms of Mittag-Leffler functions subject to initial and boundary conditions, by means of double Laplace transform.

2. A Brief Introduction of Double Laplace Transform and Caputo Fractional Derivative

Let \( f(x,t) \) be a function of two variables \( x \) and \( t \) defined in the positive quadrant of the \( xt \)-plane. The double Laplace transform of the function \( f(x,t) \) as given by Sneddon [20] is defined by

\[
L_x L_t \{ f(x,t) \} = \mathcal{F}(p,s) = \int_0^\infty e^{-px} \int_0^\infty e^{-st} f(x,t) \, dt \, dx,
\]

whenever that integral exists. Here \( p \) and \( s \) are complex numbers.

From this definition we deduce

\[
L_x L_t \{ f(x) \, g(t) \} = \mathcal{F}(p) \mathcal{G}(s) = L_x \{ f(x) \} L_t \{ g(t) \}. \tag{2}
\]

The inverse double Laplace transform \( \mathcal{L}^{-1}_x \mathcal{L}^{-1}_t \{ \mathcal{F}(p,s) \} = f(x,t) \) is defined as in [21, 22] by the complex double integral formula:

\[
\mathcal{L}^{-1}_x \mathcal{L}^{-1}_t \{ \mathcal{F}(p,s) \} = f(x,t) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} e^{ps} \frac{1}{2\pi i} \int_{d-i\infty}^{d+i\infty} e^{pt} \mathcal{F}(p,s) \, ds, \tag{3}
\]

where \( \mathcal{F}(p,s) \) must be an analytic function for all \( p \) and \( s \) in the region defined by the inequalities \( \text{Re} p \geq c \) and \( \text{Re} s \geq d \), where \( c \) and \( d \) are real constants to be chosen suitably.

The double Laplace transform formulas for the partial derivatives of an arbitrary integer order as in [23] are

\[
L_x L_t \{ \frac{\partial^m f(x,t)}{\partial x^m} \} = p^m \mathcal{F}(p,s)
\]

\[- \sum_{j=0}^{m-1} p^{m-j-1} L_t \{ \frac{\partial^j f(0,t)}{\partial t^j} \}, \tag{4}
\]

\[
L_x L_t \{ \frac{\partial^n f(x,t)}{\partial t^n} \} = s^n \mathcal{F}(p,s)
\]

\[- \sum_{k=0}^{n-1} s^{n-k-1} L_x \{ \frac{\partial^k f(x,0)}{\partial x^k} \}. \tag{5}
\]

Definition 1. The Caputo fractional derivative of function \( u(x,t) \) is defined in [18] as

\[
\frac{\partial^\alpha u(x,t)}{\partial x^\alpha} = \frac{1}{\Gamma(m - \alpha)} \int_0^x (x - \xi)^{m-\alpha-1} \frac{\partial^m f(\xi,t)}{\partial \xi^m} \, d\xi,
\]

\[m - 1 < \alpha \leq m, \, m \in \mathbb{N},\]

\[
\frac{\partial^\beta f(x,t)}{\partial t^\beta} = \frac{1}{\Gamma(n - \beta)} \int_0^t (t - \tau)^{n-\beta-1} \frac{\partial^n f(x,\tau)}{\partial \tau^n} \, d\tau,
\]

\[n - 1 < \beta \leq n, \, n \in \mathbb{N}.\]

The double Laplace transform formulas for the partial fractional Caputo derivatives as in [23] are

\[
L_x L_t \{ \frac{\partial^\alpha f(x,t)}{\partial x^\alpha} \} = p^\alpha \mathcal{F}(p,s)
\]

\[- \sum_{j=0}^{m-1} p^{\alpha-j-1} L_t \{ \frac{\partial^j f(0,t)}{\partial t^j} \}, \tag{6}
\]

\[
L_x L_t \{ \frac{\partial^\beta f(x,t)}{\partial t^\beta} \} = s^\beta \mathcal{F}(p,s)
\]

\[- \sum_{k=0}^{n-1} s^{\beta-k-1} L_x \{ \frac{\partial^k f(x,0)}{\partial x^k} \}. \tag{7}
\]

Definition 2. The Mittag-Leffler function is defined by

\[
E_{\alpha,\beta}(t) = \sum_{k=0}^{\infty} \frac{t^k}{\Gamma(\alpha k + \beta)}, \quad t, \beta \in \mathbb{C}, \ \text{Re} \ (\alpha) > 0. \tag{8}
\]

The single Laplace transform of the function \( t^{\beta-1} E_{\alpha,\beta}(\lambda t^\alpha) \) takes the form

\[
L_t \{ t^{\beta-1} E_{\alpha,\beta}(\lambda t^\alpha) \} = \frac{s^{\alpha-\beta}}{s^\alpha - \lambda}, \quad \text{for } |\lambda| < |s|, \tag{9}
\]

3. Double Laplace Transform Method

Consider the following general multiterms fractional telegraph equation as in [18]:

\[
\frac{\partial^\alpha u(x,t)}{\partial x^\alpha} = a \frac{\partial^\beta u(x,t)}{\partial t^\beta} + b \frac{\partial^\gamma u(x,t)}{\partial t^\gamma} + cu(x,t) + h(x,t), \tag{10}
\]

\[1 < \alpha, \beta \leq 2, \ 0 < \gamma \leq 1, \ x, t \geq 0,
\]

with initial conditions,

\[
u(x,0) = f_1(x), \quad u_0(x,0) = f_2(x), \tag{11}
\]

and boundary conditions,

\[
u(0, t) = g_1(t), \quad u_x(0, t) = g_2(t). \tag{12}
\]

Here \( a, b, c \) are constants and \( h(x,t) \) is given function.
Applying the double Laplace transform on both sides of (9), we get

\[ p^\alpha \bar{u}(p, s) - p^{\alpha - 1} \bar{u}(0, s) - p^{\alpha - 2} \bar{u}_x(0, s) \]
\[ = a \left[ s \bar{u}(p, s) - s^{\beta - 1} \bar{u}(p, 0) - s^{\beta - 2} \bar{u}_x(p, 0) \right] \]
\[ + b \left[ s \bar{u}(p, s) - s^{\gamma - 1} \bar{u}(p, 0) \right] + c \bar{u}(p, s) \]
\[ + \bar{h}(p, s), \]

where \( \bar{h}(p, s) = L^{-1} \{ h(x, t) \} \).

Further, applying single Laplace transform to initial (10) and boundary conditions (11), we get

\[ \bar{u}(0, s) - p^{\alpha - 1} \bar{u}(0, s) - p^{\alpha - 2} \bar{u}_x(0, s) = \frac{1}{p^\alpha - \alpha \cdot 1} \left[ p^{\alpha - 1} \bar{g}_1(s) \right] \]
\[ + \frac{p^{\alpha - 2} \bar{g}_2(s) - p^{\alpha - 1} \bar{f}_2(p) - p^{\alpha - 2} \bar{f}_2(p)}{p^{\alpha - 1} - 1} \]
\[ + \frac{-bs^{\gamma - 1} \bar{f}_1(p) + \bar{h}(p, s)}{p^{\alpha - 1} - 1}. \]

Applying inverse double Laplace transform to (14), we obtain the solution of (9) in the form

\[ u(x, t) = L_x^{-1} L_t^{-1} \left[ \frac{1}{(p^\alpha - \alpha \cdot 1) (p^{\alpha - 1} + 1)} \left[ p^{\alpha - 1} \bar{g}_1(s) \right] \right. \]
\[ + \frac{p^{\alpha - 2} \bar{g}_2(s) - p^{\alpha - 1} \bar{f}_2(p) - p^{\alpha - 2} \bar{f}_2(p)}{p^{\alpha - 1} - 1} \]
\[ \left. + \frac{-bs^{\gamma - 1} \bar{f}_1(p) + \bar{h}(p, s)}{p^{\alpha - 1} - 1} \right]. \]

Here we assume that the inverse double Laplace transform of each term in the right side of (15) exists.

4. Illustrative Examples

In this section, we demonstrate the applicability of the previous method by giving examples.

Example 1. By substituting \( a = 1, b = 1, c = 1, \beta = 2, \gamma = 1, \) and \( h(x, t) = 0 \) in (9),

\[ \frac{\partial^\alpha u(x, t)}{\partial x^\alpha} = \frac{\partial^2 u(x, t)}{\partial t^2} + \frac{\partial u(x, t)}{\partial t} + u(x, t), \]

\[ 1 < \alpha \leq 2, \ x, t \geq 0, \]

subject to the initial and boundary conditions,

\[ u(x, 0) = f_1(x) = E_a(x^\alpha) + xE_{2a}(x^\alpha), \]
\[ u_t(x, 0) = f_2(x) = -[E_a(x^\alpha) + xE_{2a}(x^\alpha)], \]
\[ u(0, t) = g_1(t) = e^{-t}, \]
\[ u_t(0, t) = g_2(t) = e^{-t}, \]
a homogeneous space-fractional telegraph equation.

Taking single Laplace transform to initial (17) and boundary conditions (18), we get

\[ \bar{f}_1(p) = \left( \frac{1}{p} + \frac{1}{p^2} \right) \frac{p^\alpha}{p^{\alpha - 1} - 1}, \]
\[ \bar{f}_2(p) = \left( \frac{1}{p} + \frac{1}{p^2} \right) \frac{p^\alpha}{p^{\alpha - 1} - 1}, \]
\[ \bar{g}_1(s) = \frac{1}{s + 1}. \]

Substituting above in (15), we get solution of (16):

\[ u(x, t) = L_x^{-1} L_t^{-1} \left[ \frac{1}{(p^\alpha - \alpha \cdot 1) (p^{\alpha - 1} + 1)} \left[ p^{\alpha - 1} \frac{1}{s + 1} \right] \right. \]
\[ + \frac{p^{\alpha - 2} \frac{1}{s + 1} - s \left( \frac{1}{p} + \frac{1}{p^2} \right) \frac{p^\alpha}{p^{\alpha - 1} - 1} \]
\[ \left. + \left( \frac{1}{p} + \frac{1}{p^2} \right) \frac{p^\alpha}{p^{\alpha - 1} - 1} - \left( \frac{1}{p} + \frac{1}{p^2} \right) \frac{p^\alpha}{p^{\alpha - 1} - 1} \right]. \]

Simplifying, we obtain

\[ u(x, t) = L_x^{-1} L_t^{-1} \left[ \frac{1}{(s + 1) (1 + \frac{1}{p^2})} \frac{p^\alpha}{p^{\alpha - 1} - 1} \right], \]
\[ u(x, t) = e^{-t} \left[ E_a(x^\alpha) + xE_{2a}(x^\alpha) \right], \]
which agrees with the solution already obtained in [18].

If we take \( \alpha = 2 \) then we get the exact solution of standard telegraph equation:

\[ u(x, t) = e^{x - t}. \]

Example 2. By substituting \( a = 1, b = 1, c = 1, \beta = 2, \gamma = 1, \) and \( h(x, t) = -x^2 - t + 1 \) in (9),

\[ \frac{\partial^\alpha u(x, t)}{\partial x^\alpha} = \frac{\partial^2 u(x, t)}{\partial t^2} + \frac{\partial u(x, t)}{\partial t} + u(x, t) - x^2 - t \]
\[ + 1, \ 1 < \alpha \leq 2, \ x, t \geq 0, \]

subject to the initial and boundary conditions,

\[ u(x, 0) = f_1(x) = x^2 - 2x^2 E_{2\alpha}(x^\alpha) + 2E_{\alpha,1}(x^\alpha), \]
\[ u_t(x, 0) = f_2(x) = 1, \]
\[ u(0, t) = g_1(t) = t, \]
\[ u_t(0, t) = g_2(t) = 0, \]
a space-fractional nonhomogeneous telegraph equation.
Taking single Laplace transform to initial (24) and boundary conditions (25), we get
\[ f_1(p) = \frac{2}{p^3} - \frac{2}{p} - 2 \frac{p^{\alpha-3}}{p^\alpha - 1} + 2 \frac{p^{\alpha-1}}{p^\alpha - 1} = \frac{2(p^2 - 1)}{p^3(p^\alpha - 1)}. \]
\[ f_2(p) = \frac{1}{p}, \]
\[ g_1(s) = \frac{1}{s^2}, \]
\[ g_2(s) = 0. \]
Taking double Laplace transform of \( h(x,t) \), we have
\[ \tilde{h}(p,s) = -2 \frac{2}{p^3} - \frac{1}{ps} + \frac{1}{ps^2}. \]
Substituting above in (15), we get solution of (23):
\[ u(x,t) = \mathcal{L}^{-1} \left[ \frac{1}{p^\alpha - s^\beta - s - 1} \left[ \frac{p^{\alpha-1}}{s^2} - \frac{1}{p} \right] \right]. \]
Rearranging, we have
\[ u(x,t) = \mathcal{L}^{-1} \left[ \frac{1}{p^\alpha - s^\beta - s - 1} \left[ \frac{p^{\alpha-1}}{s^2} - \frac{1}{p} \right] \right]. \]
Simplifying, we obtain
\[ u(x,t) = t + x^2 - 2 - 2x^2E_{\alpha,3}(x^\alpha) + 2E_{\alpha,1}(x^\alpha), \]
which agrees with the solution already obtained in [18] for \( \gamma = 1 \).
For \( \alpha = 2 \), then \( u(x,t) = t + x^2 \).

**Example 3.** By substituting \( a = 1, b = 1, c = 0, \alpha = 2, \gamma = 1 \), and \( h(x,t) = -2(t^2 - x)(t^{1-\beta}/\Gamma(3 - \beta) + 1) + 2t^2 \) in (9),
\[ \frac{\partial^\beta u(x,t)}{\partial t^\beta} + \frac{\partial u(x,t)}{\partial t} = \frac{\partial^2 u(x,t)}{\partial x^2} + 2t \left( x^2 - x \right) \left( \frac{t^{1-\beta}}{\Gamma(3 - \beta)} + 1 \right) - 2t^2, \]
\[ 1 < \beta \leq 2, x, t \geq 0, \]
subject to the initial and boundary conditions,
\[ u(x,0) = f_1(x) = 0, \]
\[ u_t(x,0) = f_2(x) = 0, \]
\[ u(0,t) = g_1(t) = 0, \]
\[ u_x(0,t) = g_2(t) = -t^2, \]
a time fractional telegraph equation in [24].
Taking single Laplace transform to initial (32) and boundary conditions (33), we get
\[ f_1(p) = f_2(p) = g_1(s) = 0, \]
\[ g_2(s) = -2 \frac{2}{s^3}. \]
Taking double Laplace transform of \( h(x,t) \), we have
\[ \tilde{h}(p,s) = -2 \frac{2}{p^3} - \frac{1}{ps} + \frac{1}{ps^2} + 2 \frac{2}{ps^3}. \]
Substituting above in (15), we get solution of (31):
\[ u(x,t) = \mathcal{L}^{-1} \left[ \frac{1}{(p^2 - s^\beta - s)^2} \right] \left[ \frac{2}{p^3} - \frac{1}{ps} \right]. \]
Simplifying, we obtain
\[ u(x,t) = \mathcal{L}^{-1} \left[ \frac{2}{p^3} - \frac{1}{ps} \right]. \]

**Example 4.** By substituting \( a = 1, b = 1, c = 1, \alpha = 2, \) and \( h(x,t) = 0 \) in (9),
\[ \frac{\partial^\beta u(x,t)}{\partial t^\beta} + \frac{\partial^\gamma u(x,t)}{\partial t^\gamma} + u(x,t) = \frac{\partial^2 u(x,t)}{\partial x^2}, \]
\[ 1 < \beta \leq 2, \frac{1}{2} < \gamma \leq 1, x, t \geq 0, \]
subject to the initial and boundary conditions,
\[ u(x,0) = f_1(x) = 0, \]
\[ u_t(x,0) = f_2(x) = e^x, \]
\[ u(0,t) = g_1(t) = tE_{\beta-\gamma,2}(-t^{\beta-\gamma}), \]
\[ u_x(0,t) = g_2(t) = tE_{\beta-\gamma,2}(-t^{\beta-\gamma}), \]
a homogeneous time fractional telegraph equation in [25].
Taking single Laplace transform to initial (39) and boundary conditions (40), we get
\[ \tilde{f}_1(p) = 0, \]
\[ \tilde{f}_2(p) = \frac{1}{p-1}, \quad (41) \]
\[ \tilde{g}_1(s) = \tilde{g}_2(s) = \frac{s^{\beta+2}}{(s^{\beta-1}+1)}. \]
Substituting above in (15), we get solution of (38):
\[ u(x,t) = L^{-1}_x L^{-1}_t \left[ \frac{1}{(p-1)} \right] \left[ (p^2 - s^\beta - s^{\beta-1} - 1) \left( \frac{s^{n-\beta}}{s+1} \right) \right]. \quad (42) \]
Simplifying, we obtain
\[ u(x,t) = e^x L^{-1}_x L^{-1}_t \left[ \frac{1}{(p-1)} \right] \left[ (p^2 - s^\beta - s^{\beta-1} - 1) \left( \frac{s^{n-\beta}}{s+1} \right) \right], \]
\[ u(x,t) = (\sinh x)^t\Gamma(n+1) \cdot \frac{2}{(s+1)^{n+1}} \cdot \frac{s^{n-\beta}}{s+1} \cdot \eta(t), \quad (50) \]
which agrees with the solution already obtained in [25].

Example 5. By substituting \( a = b = c = 1, \alpha = 2, \) and \( h(x,t) = -\sinh(tn/\Gamma(n+1)) \) in (9),
\[ \frac{\partial^\beta u(x,t)}{\partial t^\beta} + \frac{\partial^{\beta-1}u(x,t)}{\partial t^{\beta-1}} + u(x,t) = 0, \]
\[ \frac{\partial^2 u(x,t)}{\partial x^2} + \sinh x \cdot \frac{t^n}{\Gamma(n+1)}, \quad (44) \]
subject to the initial and boundary conditions,
\[ u(x,0) = f_1(x) = 0, \quad \eta(0) = 1, \]
\[ u_t(x,0) = f_2(x) = 0, \quad \eta_t(0) = 1, \]
\[ u(0,t) = g_1(t) = 0, \quad \eta(0) = 1, \]
\[ u_x(0,t) = g_2(t) = t^{\alpha+1} E_{1,\alpha+1}(-t), \quad (46) \]
a nonhomogeneous time fractional telegraph equation in [25].

Taking single Laplace transform to initial (45) and boundary conditions (46), we get
\[ \tilde{f}_1(p) = \tilde{f}_2(p) = 0, \]
\[ \tilde{g}_1(s) = 0, \quad \eta(s) = \frac{s^{n-\beta}}{s+1}. \]
Taking double Laplace transform of \( h(x,t) \), we have
\[ \tilde{h}(p,s) = \frac{-1}{(p^2 - 1)s^{n-1}}. \quad (48) \]
Substituting above in (15), we get solution of (44):
\[ u(x,t) = L^{-1}_x L^{-1}_t \left[ \frac{1}{(p^2 - 1)(s+1)} \right] \left[ s^{n-\beta} \right] \]
\[ - \frac{1}{(p^2 - 1)s^{n+1}}, \quad (49) \]
Simplifying, we obtain
\[ u(x,t) = (\sinh x)^t\Gamma(n+1) \cdot -\frac{2}{(s+1)^{n+1}} \cdot \frac{s^{n-\beta}}{s+1} \cdot \eta(t), \]
which agrees with the solution already obtained in [25].

Example 6. Consider the following space-fractional-order nonlinear telegraph equation:
\[ \frac{\partial^\alpha u(x,t)}{\partial x^\alpha} = \frac{\partial^2 u(x,t)}{\partial t^2} + \frac{\partial u(x,t)}{\partial t} + u^2(x,t) = e^{-2t} \left( x - x^2 \right)^2 - 2e^{-2t} \frac{x^{\alpha}}{\Gamma(3-\alpha)} \]
\[ 1 < \alpha \leq 2, \quad x, t \geq 0, \quad (51) \]
under the initial conditions,
\[ u(x,0) = -u_t(x,0), \quad (52) \]
and boundary conditions,
\[ u(0,t) = 0, \quad (53) \]
\[ u_x(0,t) = e^{-t}. \]
Applying the double Laplace transform on both sides of (51), we get
\[ p^n \tilde{u}(p,s) - s^{n-1} \tilde{u}(0,s) - \frac{p^{n-1}}{s^{n-1}} \tilde{u}(0,s) \]
\[ = s^2 \tilde{u}(p,s) - s \tilde{u}(0,s) \]
\[ - \tilde{u}(0,s) - 2 \frac{2}{(s+1)^{n+1}} \Gamma(3-\alpha), \quad (54) \]
Furhter, applying single Laplace transform to initial (52) and boundary conditions (53), we get
\[ \tilde{u}(0,s) = 0, \quad \eta(s) = 1, \quad (55) \]
\[ \tilde{u}_x(0,s) = \frac{1}{s+1}. \]
By substituting (55) in (54) and simplifying, we obtain
\[
(p^a - s^2 - s) \tilde{u}(p,s) = \frac{p^a}{p^2 (s+1)} - s \left[ \frac{1}{p^2} - \frac{2}{p^3} \right] + \frac{1}{p^2 - \frac{2}{p^3}} - \frac{2p^a}{(s+1)p^3} + L_x L_t \left[ u^t(x,t) - e^{-2t} (x - x^2)^2 \right],
\]
(56)
\[
(p^a - s^2 - s) \tilde{u}(p,s) = \left[ \frac{p^a}{p^2 (s+1)} - s \right] \left[ \frac{1}{p^2} - \frac{2}{p^3} \right] \left[ \frac{1}{s+1} \right] + \frac{1}{p^{a - 3} - s} L_x L_t \left[ u^t(x,t) - e^{-2t} (x - x^2)^2 \right].
\]
(57)
Applying inverse double Laplace transform of (57), we get
\[
u(x,t) = (x - x^2) e^{-x} + L_x^{-1} L_t^{-1} \left[ \frac{1}{p^a - s^2 - s} \right] \left[ u_0(x,t) \right] + L_x L_t \left[ u^t(x,t) - e^{-2t} (x - x^2)^2 \right],
\]
(58)
Now we apply the Iterative method as in [26];
\[
u(x,t) = \sum_{i=0}^{\infty} u_i(x,t).
\]
(59)
Substituting (59) in (58), we get
\[
\sum_{i=0}^{\infty} u_i(x,t) = (x - x^2) e^{-x} + L_x^{-1} L_t^{-1} \left[ \frac{1}{p^a - s^2 - s} \right] \left[ u_0(x,t) \right] + L_x L_t \left[ \sum_{i=0}^{\infty} u_i(x,t) - e^{-2t} (x - x^2)^2 \right],
\]
(60)
The nonlinear term \( N \) is decomposed as
\[
\left[ \sum_{i=0}^{\infty} u_i(x,t) \right]^2 = [u_0(x,t)]^2 + \sum_{i=1}^{\infty} \left[ \sum_{k=0}^{i-1} u_k(x,t) \right]^2 - \sum_{k=0}^{\infty} [u_k(x,t)]^2.
\]
(61)
Substituting (61) in (60), we get
\[
\sum_{i=0}^{\infty} u_i(x,t) = (x - x^2) e^{-x} + L_x^{-1} L_t^{-1} \left[ \frac{1}{p^a - s^2 - s} \right] \left[ u_0(x,t) \right] + L_x L_t \left[ \sum_{i=0}^{\infty} u_i(x,t) - e^{-2t} (x - x^2)^2 \right] + L_x L_t \left[ \sum_{i=0}^{\infty} \left[ \sum_{k=0}^{i-1} u_k(x,t) \right]^2 - \sum_{k=0}^{\infty} [u_k(x,t)]^2 \right].
\]
(62)
Then we define the recurrence relations as
\[
u_0(x,t) = (x - x^2) e^{-x},
\]
\[
u_1(x,t) = L_x^{-1} L_t^{-1} \left[ \frac{1}{p^a - s^2 - s} \right] \left[ u_0(x,t) \right]^2 - e^{-2t} (x - x^2)^2 \right] = 0,
\]
\[
u_2(x,t) = L_x^{-1} L_t^{-1} \left[ \frac{1}{p^a - s^2 - s} \right] \left[ u_0(x,t) + u_1(x,t) \right]^2 - \left[ u_0(x,t) \right]^2 = 0,
\]
and so on.
Therefore, we obtain the solution of (51) as follows:
\[
u(x,t) = e^{-2t}.
\]
(64)
This is the required exact solution of (51).

5. Conclusion
We have applied double Laplace transform to obtain exact solutions of linear/nonlinear space-time fractional telegraph equations. All of the examples considered show that double Laplace transform method is capable of reducing the volume of computational work as compared to other methods. It may be concluded that DLT technique solves the problems without using Adomian polynomials, Lagrange multiplier value, He's polynomials, and small parameters.
