For the tuple set of commuting invertible matrices with coefficients in a given field, the joint determinants are defined as generalizations of the determinant map for the square matrices. We introduce a natural topology on Milnor’s $K$-groups of a topological field as the quotient topology induced by the joint determinant map and investigate the existence of a nontrivial continuous joint determinant by utilizing this topology, generalizing the author’s previous results on the continuous joint determinants for the commuting invertible matrices over $\mathbb{R}$ and $\mathbb{C}$.

1. Introduction

In [1], a joint determinant is introduced as a generalization of the determinant map for invertible matrices. More precisely, for a field $k$, a joint determinant $D (= D_k) (l \geq 1)$ is defined as the map from the set of $l$-tuples of commuting matrices in $\text{GL}_n(k)$ ($n \geq 1$) into some abelian group $(G, +)$ which satisfies the following properties.

(i) Multilinearity: for $l + 1$ commuting matrices $A_1, \ldots, A_l$ and $B$ in $\text{GL}_n(k)$ for some $n \geq 1$, we have $D(A_1, \ldots, A_l, B) = D(A_1, \ldots, A_l) + D(B)$.

(ii) Block diagonal matrices: for commuting matrices $A_1, \ldots, A_l \in \text{GL}_n(k)$ and commuting $B_1, \ldots, B_l \in \text{GL}_n(k)$ for some $m, n \geq 1$, we have

$$D\left(\begin{pmatrix} 0 & \cdots & 0 \\ A_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & B_1 \end{pmatrix}\right) = D(A_1, \ldots, A_l) + D(B_1, \ldots, B_l).$$

(iii) Similar matrices: for commuting matrices $A_1, \ldots, A_l \in \text{GL}_n(k)$ and any $S \in \text{GL}_l(k)$, we have $D(SA_1S^{-1}, \ldots, SA_lS^{-1}) = D(A_1, \ldots, A_l)$.

(iv) Polynomial homotopy: for commuting $A_1(t), \ldots, A_l(t) \in \text{GL}_n(k[t])$, we have $D(A_1(0), \ldots, A_l(0)) = D(A_1(1), \ldots, A_l(1))$.

Using the standard inclusion $\text{GL}_n(k) \hookrightarrow \text{GL}_{n+1}(k)$

$$\begin{pmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{pmatrix} \mapsto \begin{pmatrix} a_{11} & \cdots & a_{1n} & 0 \\ \vdots & \ddots & \vdots & \vdots \\ a_{n1} & \cdots & a_{nn} & 0 \\ 0 & \cdots & 0 & 1 \end{pmatrix},$$

we define $\text{GL}(k)$ as the direct limit of these groups $\text{GL}(k) = \bigcup_{n \to \infty} \text{GL}_n(k)$. Using the above inclusions, we may identify the direct limit $\text{Comm}_l(k)$ of the set of $l$-tuples of commuting matrices in $\text{GL}_n(k)$, $\text{GL}_n(k) = \text{GL}_n(k) \times \cdots \times \text{GL}_n(k)$ over $n$ as a subset of $\text{GL}(k) = \text{GL}(k) \times \cdots \times \text{GL}(k)$. Then, a joint determinant may be thought of as a map from $\text{Comm}_l(k)$ into an abelian group $G$.

The main result in [1] about the joint determinants is that there exists a one-to-one correspondence between the set of joint determinants from $\text{Comm}_l(k)$ into an abelian group $G$ and the set of group homomorphisms from Milnor’s $K$-group $K_l^M(k)$ into $G$. Milnor’s $K$-group is introduced in [2] as the quotient group of the tensor product $k^* \otimes \cdots \otimes k^*$ by the subgroup generated by elements of the form $a_i - a_j$, where $a_i + a_j = 1$ for some $i, j (1 \leq i < j \leq l)$. It is a major object of study in algebraic $K$-theory and appears in numerous literatures. For example, Voevodsky’s proof of
Bloch-Kato conjecture [3] relates Milnor’s $K$-group of a field with its étale cohomology. The element of $K^M_l(k)$ represented by $a_1 \otimes \cdots \otimes a_l$ is typically denoted by a symbol $\{a_1, \ldots, a_l\}$.

To describe the “universal” joint determinant $\text{Comm}_l(k) \to K^M_l(k)$, we need the Goodwillie group $GW_l(k)$ which is defined to be the abelian group generated by $l$-tuples of commuting matrices $(A_1, \ldots, A_l)$ ($A_1, \ldots, A_l \in GL_n(k)$ for each $n \geq 1$), subject to the following 4 kinds of relations.

(i) Identity matrices: $(A_1, \ldots, A_l) = 0$ when $A_i$ for some $i$ is equal to the identity matrix $I_n \in GL_n(k)$.

(ii) Similar matrices: $(A_1, \ldots, A_l) = (S A_1 S^{-1}, \ldots, S A_l S^{-1})$ for commuting $A_1, \ldots, A_l \in GL_n(k)$ and any $S \in GL_n(k)$.

(iii) Direct sum: $(A_1, \ldots, A_l) + (B_1, \ldots, B_l) = \left(\left(\begin{array}{cc} A_1 & 0 \\ 0 & B_1 \end{array}\right), \ldots, \left(\begin{array}{cc} A_l & 0 \\ 0 & B_l \end{array}\right)\right)$ for commuting $A_1, \ldots, A_l \in GL_n(k)$ and commuting $B_1, \ldots, B_l \in GL_m(k)$.

(iv) Polynomial homotopy: $(A_1(0), \ldots, A_l(0)) = (A_1(1), \ldots, A_l(1))$ for commuting matrices $A_1(t), \ldots, A_l(t)$ in $GL_n([k[t]])$, where $k[t]$ is the polynomial ring over $k$ with the indeterminate $t$.

The universal joint determinant map $\Phi_1 : \text{Comm}_l(k) \to K^M_l(k)$ is then the composite of the natural map $\text{Comm}_l(k) \to GW_l(k)$, which sends an $l$-tuple of commuting matrices to a generator of $GW_l(k)$ and the isomorphism $\phi_l : GW_l(k) \to K^M_l(k)$, which is described in the proof of Theorem 6.7 of [1]. From the fact that $\phi$ is an isomorphism follows easily the one-to-one correspondence between the set of joint determinants from $\text{Comm}_l(k)$ into an abelian group $G$ and the set of group homomorphisms from Milnor’s $K$-group $K^M_l(k)$ into $G$.

When $l = 1$, $GW_1(k) = k^*$ and the universal joint determinant is nothing but the traditional determinant map (Proposition 4.4 of [1]).

The definition of joint determinant maps is given in purely algebraic terms and so there are possibilities of very complicated joint determinants; for example, when $k$ is the field $\mathbb{C}$ of complex numbers or $\mathbb{R}$ of real numbers, Milnor’s $K$-groups $K^M_l(k)$ for $l \geq 2$ are known to be uniquely divisible or a direct sum of a cyclic group of order 2 and a uniquely divisible group, respectively [2].

Thus, if we disregard the topological continuity of a joint determinant map, the joint determinants are far from trivial, but if we require a joint determinant to be continuous, then the situation becomes drastically different. It is proven that, for $l \geq 2$, there exists only one nontrivial joint determinant from $\text{Comm}_l(R)$ into $R^*$, which is continuous when restricted to the set of commuting matrices in $GL_n(R)$, for each $n$, with the standard topology (Corollary 7.3 of [1]).

In the present article, we generalize this result to determine all possible continuous joint determinants from $\text{Comm}_l(R)$ or $\text{Comm}_l(C)$ to a topological abelian group $G$. For this purpose, we introduce a natural topology on Milnor’s $K$-groups $K^M_l(k)$ for a topological field $k$ as the quotient topology induced by the joint determinant map and show that, in case of $k = \mathbb{R}$ or $\mathbb{C}$, the natural topology on $K^M_l(k)$ is disjoint union of two indiscrete components or indiscrete topology, respectively. This indicates that, for $k = \mathbb{R}$ or $\mathbb{C}$, the “universal” continuous joint determinant turns out to be $\text{Comm}_l(\mathbb{R}) \to \mathbb{Z}_2$ or $\text{Comm}_l(\mathbb{C}) \to \{1\}$, respectively.

2. A Natural Topology on $K^M_l(k)$

For a topological field $k$, $GL(k) = \bigcup_{n=\infty} GL_n(k)$ is a topological group with the direct limit topology, that is, a subset $U$ of $GL(k)$ is open if and only if $U \cap GL_n(k)$ is open for each $n \geq 1$ (e.g., 3.1 of [4]). The topology on $\text{Comm}_l(k)$ is given by the subspace topology regarding it as a subspace of the product space $GL(k)^l = GL(k) \times \cdots \times GL(k)$. Then it coincides with the direct limit topology if we think of $\text{Comm}_l(k)$ as the direct limit of the subspace of $l$-tuples of commuting matrices in the space $GL_n(k)^l = GL_n(k) \times \cdots \times GL_n(k)$ over $n$.

Definition 1. For a topological field $k$, the topology on Milnor’s $K$-group $K^M_l(k)$ is the quotient topology with respect to the map $\Phi_1 : \text{Comm}_l(k) \to K^M_l(k)$, which is the composite of a natural map $\text{Comm}_l(k) \to GW_l(k)$ followed by the group isomorphism $\phi_l : GW_l(k) \to K^M_l(k)$ which is described in the proof of Theorem 6.7 of [1].

The obvious map $\text{Comm}_l(k) \to GW_l(k)$ is actually surjective by Corollary 4.3 of [1] and so $\Phi_1$ is a surjection.

Theorem 2. $K^M_l(k)$ is a topological group with respect to the topology given in Definition 1.

Proof. By the definition of the Goodwillie group $GW_l(k)$, the group law on $K^M_l(k)$ is given via $\phi_l : GW_l(k) \to K^M_l(k)$ by the direct sum rule: $(A_1, \ldots, A_l) + (B_1, \ldots, B_l) = \left(\left(\begin{array}{cc} A_1 & 0 \\ 0 & B_1 \end{array}\right), \ldots, \left(\begin{array}{cc} A_l & 0 \\ 0 & B_l \end{array}\right)\right)$ for commuting $A_1, \ldots, A_l \in GL_n(k)$ and commuting $B_1, \ldots, B_l \in GL_n(k)$ ($p, q \geq 1$). This addition rule is not expressed by a continuous map $\text{Comm}_l(k) \times \text{Comm}_l(k) \to \text{Comm}_l(k)$, but the following continuous map $\text{Comm}_l(k) \times \text{Comm}_l(k) \to \text{Comm}_l(k)$ actually induces the group operation on $K^M_l(k)$:

\[
\begin{pmatrix}
    a_{11} & a_{12} & a_{13} \\
    a_{21} & a_{22} & a_{23} \\
    a_{31} & a_{32} & a_{33} \\
    \vdots & \vdots & \vdots
\end{pmatrix}
\begin{pmatrix}
    b_{11} & b_{12} & b_{13} \\
    b_{21} & b_{22} & b_{23} \\
    b_{31} & b_{32} & b_{33} \\
    \vdots & \vdots & \vdots
\end{pmatrix}
= 
\begin{pmatrix}
    \ldots & \ldots & \ldots \\
    \ldots & \ldots & \ldots \\
    \ldots & \ldots & \ldots
\end{pmatrix}
\]
To prove that the two elements

\[
\begin{pmatrix}
  a_{11} & 0 & a_{13} & 0 & \cdots \\
  0 & b_{11} & b_{12} & b_{13} & \cdots \\
  a_{21} & a_{22} & a_{23} & 0 & \cdots \\
  0 & b_{21} & 0 & b_{22} & b_{23} & \cdots \\
  a_{31} & a_{32} & a_{33} & 0 & \cdots \\
  0 & b_{31} & 0 & b_{32} & b_{33} & \cdots \\
  \vdots & \vdots & \vdots & \vdots & \ddots
\end{pmatrix}
\]

and

\[
\begin{pmatrix}
  a_{11} & a_{12} & \cdots & 0 & 0 & \cdots \\
  0 & a_{21} & a_{22} & \cdots & 0 & \cdots \\
  \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
  0 & 0 & \cdots & b_{11} & b_{12} & \cdots \\
  0 & 0 & \cdots & b_{21} & b_{22} & \cdots \\
  \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
\end{pmatrix}
\]

of Comm\(_l\)(k) map to the same element under \(\Phi_l\) : Comm\(_l\)(k) \(\rightarrow\) \(K_l^M\)(k), it is enough to verify that an \(l\)-tuple \((A_1, \ldots, A_l)\) of commuting matrices in GL\(_n\)(k)\(^l\) represents the same element in GW\(_l\)(k) which is represented by the \(l\)-tuple of matrices which is obtained by simultaneously changing \(i\)th and \(j\)th rows and also \(i\)th and \(j\)th columns of all \(l\) \(n\times n\) matrices \(A_1, \ldots, A_l\). For notational convenience, we will prove this for 1st and 2nd rows and columns of \(2\times 2\) matrices and the proof is easily generalized to \(n\times n\) matrices. Let us write the \((i, j)\)th entry of the matrix \(A_k\) as \(a_{ij}^k\) \((k = 1, 2, \ldots, l)\). In GW\(_l\)(k), we have

\[
(A_1, \ldots, A_l) = \left( \begin{pmatrix} a_{11} & a_{12} & 0 & 0 \\ a_{21} & a_{22} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \ldots, \begin{pmatrix} d_{11} & d_{12} & 0 & 0 \\ d_{21} & d_{22} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \right).
\]

Using the polynomial homotopy

\[
\begin{pmatrix}
  1 - t^2 & 0 & 0 & t \\
  0 & 1 & 0 & 0 \\
  0 & 0 & 1 & 0 \\
  t^3 - 2t & 0 & 0 & 1 - t^2
\end{pmatrix}
\]

\[
\begin{pmatrix}
  1 - t^2 & 0 & 0 & t \\
  0 & 1 & 0 & 0 \\
  0 & 0 & 1 & 0 \\
  t^3 - 2t & 0 & 0 & 1 - t^2
\end{pmatrix}
\]

\[
\begin{pmatrix}
  1 - t^2 & 0 & 0 & t \\
  0 & 1 & 0 & 0 \\
  0 & 0 & 1 & 0 \\
  t^3 - 2t & 0 & 0 & 1 - t^2
\end{pmatrix}
\]

\[
\begin{pmatrix}
  1 - t^2 & 0 & 0 & t \\
  0 & 1 & 0 & 0 \\
  0 & 0 & 1 & 0 \\
  t^3 - 2t & 0 & 0 & 1 - t^2
\end{pmatrix}
\]
which results in interchanging the 1st and 4th rows with negative sign to the new 4th row and then interchanging 1st and 4th columns with negative sign to the new 4th column, we see that, in GW$_{i}(k)$,

\[
\begin{pmatrix}
  a_{11}^i & a_{12}^i & 0 & 0 \\
  a_{21}^i & a_{22}^i & 0 & 0 \\
  0 & 0 & 1 & 0 \\
  0 & 0 & 0 & 1
\end{pmatrix}
\]

Again, by applying the polynomial homotopy

\[
\begin{pmatrix}
  1 & 0 & 0 & 0 \\
  0 & 1 & -t^2 & t \\
  0 & t^3 - 2t & 1 - t^2 & 0 \\
  0 & 0 & 0 & 1
\end{pmatrix}
\]

which results in interchanging the 2nd and 3rd rows with negative sign to the new 3rd row and then interchanging 2nd and 3rd columns with negative sign to the new 3rd column, we have, in GW$_{i}(k)$,

\[
\begin{pmatrix}
  1 & 0 & 0 & 0 \\
  0 & a_{12}^i & 0 & a_{12}^i \\
  0 & 0 & 1 & 0 \\
  0 & 0 & a_{12}^i & 0 & a_{12}^i
\end{pmatrix}
\]

which is equal to \( \left( \begin{pmatrix} a_{12}^i, a_{21}^i \\ a_{22}^i, a_{11}^i \end{pmatrix}, \ldots, \begin{pmatrix} a_{12}^i, a_{21}^i \\ a_{22}^i, a_{11}^i \end{pmatrix} \right) \) in GW$_{i}(k)$.

3. The Topological Structures of \( K_{i}^{M}(\mathbb{R}) \) and \( K_{i}^{M}(\mathbb{C}) \)

**Theorem 3.** For \( l \geq 2 \), the topological space \( K_{i}^{M}(\mathbb{R}) \) is a disjoint union of two indiscrete open sets.

**Proof.** Note that we have \( K_{i}^{M}(\mathbb{R}) = (\mathbb{Z}/2) \oplus H \), where the first direct factor \( \mathbb{Z}/2 \) is generated by \( \{-1, \ldots, -1\} \) and \( H \) is a uniquely divisible group \([2]\). For \( \{a_{1}, \ldots, a_{l}\} \) where \( a_{i} \) are negative for all \( i = 1, \ldots, l \), we have \( \{a_{1}, \ldots, a_{l}\} = \{-1, a_{2}, \ldots, a_{l}\} + \{-a_{1}, a_{2}, \ldots, a_{l}\} = \{-1, -a_{1}, \ldots, a_{l}\} + \{-a_{1}, a_{2}, \ldots, a_{l}\} = \cdots \) which is equal to the sum of \( \{-1, -1, -1, \ldots, -1\} \) and various symbols of the form \( \{b_{1}, \ldots, b_{j}\} \) where at least one of \( b_{j} \) is positive.

Every element of \( H \) can be written as a sum of symbols of the form \( b_{1}, \ldots, b_{j} \) where at least one of \( b_{j} \) is positive. By writing a positive real number as a square of its square root, we may assume that \( b_{j} \) is positive for every \( i = 1, \ldots, l \) (e.g., \( \{b_{1}, b_{2}\} = \{b_{1}, \sqrt{b_{2}}\} \) in case \( b_{2} > 0 \)).

Let \( U \) be any open set of \( K_{i}^{M}(\mathbb{R}) \) containing the identity element and consider its inverse image \( V = \Phi_{i}^{-1}(U) \) in \( \text{Comm}_{i}(\mathbb{R}) \). Let \( h \in H \) be any element. Then
continuous if Comm

By taking matrices where the determinants of $a_i$ are negative for all $i = 1, \ldots, l$. Similarly, the coset $H + \{-1, -1, \ldots, -1\}$ is also an indiscr
e

try for $k = \mathbb{R}$ and $k = \mathbb{C}$ in the following theorem, which is virtually equivalent to Theorem 3 and Corollary 4.

**Theorem 7.** For $k = \mathbb{R}$ or $k = \mathbb{C}$ and a topological abelian group $G$, let $D : \text{Comm}_l(k) \to G$ be a con
tinuous joint determinant. When $l = 1$, $D$ is a composite of the usual determinant map followed by a canonical epimorphism $K' \to G$ with $G$ equipped with a coarser topology than the quotient topology induced by the epimorphism. When $k = \mathbb{R}$ and $l \geq 2$, $G$ either is an indiscrete space or has an indiscrete subgroup of index 2. If $k = \mathbb{C}$, then $G$ has the indiscrete topology.
