ABSTRACT

This paper discusses the convergence of random Ishikawa iteration scheme to a random fixed point for a certain class of random operators.

Key words: Random fixed point, random Ishikawa iteration, Tricomi's condition, Hilbert space, random operator.

AMS subject classification: 47H10, 47H40.

1. Introduction

In recent years the study of random fixed points have attracted a great amount of attention. Discussions on random fixed points may be found in works such as [1], [2], [6], and [7]. We review the following concepts which are essentials for the purpose of our discussion. Throughout this paper, (T, Σ) denotes a measurable space, and H denotes a separable Hilbert space.

A function $f: T \rightarrow H$ is said to be *measurable* if $f^{-1}(B) \in \Sigma$ for every Borel subset B of H .

Let C be any subset of H . A function $f: T \rightarrow C$ is said to be *measurable* if $f^{-1}(B \cap C) \in \Sigma$ for every Borel subset B of H .

A function $F: T \times H \rightarrow H$ is said to be *H-continuous* if $F(t, \cdot): H \rightarrow H$ is continuous for every $t \in T$.

A function $F: T \times H \rightarrow H$ is said to be a *random operator* if $F(\cdot, x): T \rightarrow H$ is measurable for every $x \in H$.

A measurable function $g: T \rightarrow H$ is said to be a *random fixed point* of $F: T \times H \rightarrow H$ if $F(t, g(t)) = g(t)$ for all $t \in T$.

The Ishikawa iteration scheme was obtained in [5]. We define the random Ishikawa iteration scheme in an analogous manner as follows:

Let $g_0: T \rightarrow H$ be any measurable function. The functions below are iteratively defined as follows:

$$g_{n+1}(t) = \alpha_n F(t, h_n(t)) + (1 - \alpha_n)g_n(t), \quad n \geq 0, \quad t \in T. \quad (1)$$

where

$$h_n(t) = \beta_n F(t, g_n(t)) + (1 - \beta_n)g_n(t), \quad n \geq 0, \quad t \in T. \quad (2)$$

and $\{\alpha_n\}$ and $\{\beta_n\}$ are sequences of real numbers such that

$$0 < \alpha_n, \beta_n < 1 \text{ for all } n \geq 0 \quad (3)$$

$$\lim_{n \rightarrow \infty} \sup \beta_n = M < 1 \quad (4)$$

and

$$\sum_{n=1}^{\infty} \alpha_n \beta_n = \infty. \quad (5)$$

Let $C \subset H$, $k: C \rightarrow C$ is said to satisfy Tricomi's condition in C if $p \in C$ and $k(p) = p$ imply

$$\|k(x) - p\| \leq \|x - p\| \text{ for all } x \in C. \quad (6)$$

The following lemma was proved in [5]:

Lemma: H is a Hilbert space; therefore for any $x, y, z \in H$ and any real λ

$$\|\lambda x + (1 - \lambda)y - z\|^2 = \lambda \|x - z\|^2 + (1 - \lambda) \|y - z\|^2 - \lambda(1 - \lambda) \|x - y\|^2 \quad (7)$$

2. Main Result

Theorem 1: Let H be a separable Hilbert space. $F: T \times H \rightarrow H$ is an H -continuous random operator in which case there exists $f: T \rightarrow H$ (not necessarily measurable) such that

$$\|F(t, x) - f(t)\| \leq \|x - f(t)\| \quad (8)$$

for all $t \in T$ and $x \in H$.

Then, for any measurable function $g_0: T \rightarrow H$, the sequence of functions $\{g_n\}$ defined by the random Ishikawa iteration scheme, if convergent, converges to a random fixed point of F .

Proof: For any $t \in T$,

$$\begin{aligned} & \|g_{n+1}(t) - f(t)\|^2 \\ &= \|\alpha_n F(t, h_n(t)) + (1 - \alpha_n)g_n(t) - f(t)\|^2 \\ &= \alpha_n \|F(t, h_n(t)) - f(t)\|^2 + (1 - \alpha_n) \|g_n(t) - f(t)\|^2 \\ &\quad - \alpha_n(1 - \alpha_n) \|F(t, h_n(t)) - g_n(t)\|^2 \text{ (by (7))} \\ &\leq \alpha_n \|F(t, h_n(t)) - f(t)\|^2 + (1 - \alpha_n) \|g_n(t) - f(t)\|^2 \text{ (by (3))} \\ &\leq \alpha_n \|h_n(t) - f(t)\|^2 + (1 - \alpha_n) \|g_n(t) - f(t)\|^2 \text{ (by (8))} \\ &\leq \|g_n(t) - f(t)\|^2 - \alpha_n \beta_n (1 - \beta_n) \|F(t, g_n(t)) - g_n(t)\|^2 \end{aligned}$$

(by using (2), (7) and (8)).

It further implies that

$$\begin{aligned} & \sum_{n=0}^N \alpha_n \beta_n (1 - \beta_n) \|F(t, g_n(t)) - g_n(t)\|^2 \\ & \leq \|g_0(t) - f(t)\|^2 - \|g_{N+1}(t) - f(t)\|^2 \\ & \leq \|g_0(t) - f(t)\|^2 < \infty. \end{aligned} \quad (9)$$

For M' satisfying $M < M' < 1$, there exists a positive integer m_0 such that $\beta_m < M'$ for all $m \geq m_0$ (by (4)). Therefore, $1 - \beta_m > 1 - M' > 0$ for all $m \geq m_0$, or

$$\sum_{m=m_0}^{\infty} \alpha_m \beta_m (1 - \beta_m) \geq (1 - M') \sum_{m=m_0}^{\infty} \alpha_m \beta_m = \infty \quad (10)$$

(9) and (10) imply,

$$\lim_{n \rightarrow \infty} \inf \|F(t, g_n(t)) - g_n(t)\| = 0 \text{ for all } t \in T. \quad (11)$$

Hence, if $\{g_n(t)\}$ converges, for example to $g(t)$, $F(t, g_n(t))$ also converges to $g(t)$.

Since $F: T \times H \rightarrow H$ is an H -continuous random operator and H is separable, $\{g_n\}$ is a sequence of measurable functions [4]. Therefore, $g = \lim_{n \rightarrow \infty} g_n$ is measurable. Furthermore, F is H -continuous; thus, for all $t \in T$,

$$\begin{aligned} g(t) &= \lim_{n \rightarrow \infty} g_n(t) = \lim_{n \rightarrow \infty} F(t, g_n(t)) \\ &= F(t, \lim_{n \rightarrow \infty} g_n(t)) = F(t, g(t)). \end{aligned}$$

Hence, g is a random fixed point of F .

Therefore, $\{g_n\}$ (if convergent) converges to a random fixed point of F .

Theorem 2: Let $C \subset H$ be a convex and compact subset and $F: T \times C \rightarrow C$ satisfies

- a) F is H -continuous;
- b) there exists $f: T \rightarrow C$ such that $\|F(t, x) - f(t)\| \leq \|x - f(t)\|$ for all $t \in T$ and $x \in C$;
- and
- c) $F(t, \cdot): C \rightarrow C$ satisfies Tricomi's condition in C for every $t \in T$.

Then, for any measurable function $g_0: T \rightarrow C$, the sequence $\{g_n\}$ of measurable functions constructed by the random Ishikawa iteration scheme converges to a random fixed point of F .

Proof: Since C is convex and compact, H is a separable Hilbert space and F is an H -continuous random operator and $\{g_n\}$ is a sequence of measurable functions from C to C . Proceeding exactly as in Theorem 1, we obtain (as in (11))

$$\lim_{n \rightarrow \infty} \inf \|F(t, g_n(t)) - g_n(t)\| = 0.$$

Therefore, for fixed $t \in T$, there exists $\{g_{n_i}(t)\} \subset \{g_n(t)\}$ such that

$$\lim_{i \rightarrow \infty} \|F(t, g_{n_i}(t)) - g_{n_i}(t)\| = 0. \quad (12)$$

Since C is compact, there exists $\{g_{n_{i_k}}(t)\} \subset \{g_{n_i}(t)\}$, such that $\{g_{n_{i_k}}(t)\}$ is convergent.

Let

$$\lim_{k \rightarrow \infty} g_{n_{i_k}}(t) = g(t). \quad (13)$$

From (12) and (13), and since $\{g_{n_{i_k}}(t)\} \subset \{g_{n_i}(t)\}$, we have

$$\lim_{k \rightarrow \infty} F(t, g_{n_{i_k}}(t)) = g(t),$$

or

$$F(t, g(t)) = g(t) \text{ (since } F \text{ is } H\text{-continuous).} \quad (14)$$

Hence, for fixed $t \in T$, $g(t)$ is a fixed point of $F(t, \cdot)$.

For any fixed $t \in T$,

$$\begin{aligned} \|g_{n+1}(t) - g(t)\|^2 &= \|\alpha_n F(t, h_n(t)) + (1 - \alpha_n)g_n(t) - g(t)\|^2 \\ &= \alpha_n \|F(t, h_n(t)) - g(t)\|^2 + (1 - \alpha_n) \|g_n(t) - g(t)\|^2 \end{aligned}$$

$$\begin{aligned}
& -\alpha_n(1-\alpha_n) \|F(t, h_n(t)) - g_n(t)\|^2 \text{ (by (7))} \\
\leq & \alpha_n \|h_n(t) - g(t)\|^2 + (1-\alpha_n) \|g_n(t) - g(t)\|^2 \text{ (by (3) and Tricomi's condition (6))} \\
& = \alpha_n \|\beta_n F(t, g_n(t)) + (1-\beta_n)g_n(t) - g(t)\|^2 + (1-\alpha_n) \|g_n(t) - g(t)\|^2 \\
& = \alpha_n(\beta_n \|F(t, g_n(t)) - g(t)\|^2 + (1-\beta_n) \|g_n(t) - g(t)\|^2 \\
& - \beta_n(1-\beta_n) \|F(t, g_n(t)) - g_n(t)\|^2) + (1-\alpha_n) \|g_n(t) - g(t)\|^2 \text{ (by (7))} \\
& \leq \alpha_n(\beta_n \|g_n(t) - g(t)\|^2 + (1-\beta_n) \|g_n(t) - g(t)\|^2) \\
& + (1-\alpha_n) \|g_n(t) - g(t)\|^2 \text{ (by (3) and Tricomi's condition (6))} \\
& = \alpha_n \|g_n(t) - g(t)\|^2 + (1-\alpha_n) \|g_n(t) - g(t)\|^2 \\
& = \|g_n(t) - g(t)\|^2.
\end{aligned}$$

Therefore, for $t \in T$,

$$\|g_{n+1}(t) - g(t)\| \leq \|g_n(t) - g(t)\|. \quad (15)$$

Since $\{g_{n_{i_k}}(t)\} \rightarrow g(t)$, given $\epsilon > 0$, there exists $n_{i_{k_0}}$ such that

$$\|g_{n_{i_{k_0}}}(t) - g(t)\| < \epsilon.$$

By virtue of (15),

$$\|g_n(t) - g(t)\| < \epsilon \text{ for all } n \geq n_{i_{k_0}}.$$

Therefore, for $t \in T$, $\lim_{n \rightarrow \infty} g_n(t) = g(t)$. Since $\{g_n\}$ is a sequence of measurable functions, g is also measurable. Thus, $g: T \rightarrow C$ is a random fixed point of $F: T \times C \rightarrow C$.
