The aim of this paper is to introduce a symbolic technique for the computation of the solution to a complete ordinary differential equation with constant coefficients. The symbolic solution is computed via the variation of parameters method and, thus, constructed over the exponential matrix of the linear system associated with the homogeneous equation. This matrix is also symbolically determined. The accuracy of the symbolic solution is tested by comparing it with the exact solution of a test problem.

1. Introduction

Perturbation theories for differential equations containing a small parameter \( \epsilon \) are quite old. The small perturbation theory originated by Sir Isaac Newton has been highly developed by many others, and an extension of this theory to the asymptotic expansion, consisting of a power series expansion in the small parameter, was devised by Poincaré [1]. The main point is that, for the most of the differential equations, it is not possible to obtain an exact solution. In cases where equations contain a small parameter, we can consider it as a perturbation parameter to obtain an asymptotic expansion of the solution. In practice, the work involved in the application of this approach to compute the solution to a differential equation cannot be performed by hand, and algebraic processors result in being a very useful tool.

As explained in Henrard [2], the first symbolic processors were developed to work with Poisson series, that is, multivariate Fourier series whose coefficients are multivariate Laurent series,

\[
\sum_{i_1, \ldots, i_n} \sum_{j_1, \ldots, j_m} C_{i_1, \ldots, i_n, j_1, \ldots, j_m} x_1^{i_1} \cdots x_n^{i_n} y_1^{j_1} \cdots y_m^{j_m} \frac{\cos (j_1 \phi_1 + \cdots + j_m \phi_m)}{\sin (j_1 \phi_1 + \cdots + j_m \phi_m)},
\]

(1)

where \( C_{i_1, \ldots, i_n, j_1, \ldots, j_m} \in \mathbb{R} \), \( i_1, \ldots, i_n, j_1, \ldots, j_m \in \mathbb{Z} \), and \( x_1, \ldots, x_n \) and \( \phi_1, \ldots, \phi_m \) are called polynomial and angular variables, respectively. These processors were applied to problems in nonlinear mechanics or nonlinear differential equation problems, in the field of celestial mechanics. One of the first applications of these processor was concerned with the theory of the Moon. Delaunay invented his perturbation method to treat it and spent 20 years doing algebraic manipulations by hand to apply it to the problem. Deprit et al. [3, 4] prolonged the solution of Delaunay’s work with the help of a special purpose symbolic processor, and Henrard [5] pushed to order 25. This solution was improved by iteration by Chapront-Touze [6], and planetary perturbations were also introduced by Chapront-Touze [7]. At present, the most complete solution, Ephemeride Lunaire Parisien (ELP) contains more than 50 000 periodic terms. But the motion of the Moon is not the only application of algebraic processors. There are many problems where the facilities provided by Poisson series processors can lead rather quickly to very accurate results. As examples, we would like to mention planetary theories, the theory of the rotation of the Earth (see, e.g. Navarro and Ferrándiz [8]), and artificial satellite theories.

In order to achieve better accuracies in the applications of analytical theories, high orders of the approximate solution must be computed, making necessary a continuous maintenance and revision of the existing symbolic manipulation systems, as well as the development of new packages adapted...
to the peculiarities of the problem to be treated. Recently, Navarro [9, 10] developed a symbolic processor to deal with the solution to second order differential equations of the form

\[ \ddot{x} + a_1 \dot{x} + a_0 x = u(t) + \epsilon f(x, \dot{x}), \]  

with initial conditions

\[ x(0) = x_0, \quad \dot{x}(0) = \dot{x}_0, \]  

where \( a_0, a_1, x_0, \) and \( \dot{x}_0 \) are in \( \mathbb{R} \), \( u(t) \) is a quasipolynomial, that is, an object of the form

\[ u(t) = \sum_{n=0}^{M} t^n e^{a_{n,t}} \left( \lambda_{n,t} \cos(\omega_{n,t}) + \mu_{n,t} \sin(\omega_{n,t}) \right), \]  

where \( n_{n,t} \in \mathbb{N}, \lambda_{n,t}, \omega_{n,t}, \) and \( \mu_{n,t} \) are in \( \mathbb{R} \), and \( f(x, \dot{x}) \) admits the expansion

\[ f(x, \dot{x}) = \sum_{x=0}^{M} \sum_{0 \leq y \leq x} f_{x-y} x^{x-y}, \quad f_{x-y} \in \mathbb{R}. \]  

To face this problem, the algebraic processor handles objects called quasipolynomials, and it has resulted in being a useful tool in the computation of the solution to (2) by the application of the asymptotic expansion method. A modification of this processor has been employed to compute periodic solutions in equations of type (2) via the Poincaré–Lindstedt method in Navarro [9, 10]. To that end, the idea is to expand both the solution and the modified frequency with respect to the small parameter, allowing to kill secular terms which appear in the recursive scheme. The elimination of secular terms is performed through a manipulation system which works with modified quasipolynomials, that is, quasipolynomials containing undetermined constants:

\[ u(t) = \sum_{n=0}^{M} \prod_{q=1}^{n} t^{\sigma_q} \times \prod_{q=1}^{n} t_{q}^{\sigma_q} e^{a_{n,t}} \left( \lambda_{n,t} \cos(\omega_{n,t}) + \mu_{n,t} \sin(\omega_{n,t}) \right), \]  

where \( n_{n,t} \in \mathbb{N}, \sigma_q, \lambda_{n,t}, \omega_{n,t}, \) and \( \mu_{n,t} \) are in \( \mathbb{R} \), \( \sigma_q \in \mathbb{Z} \), and \( n, \sigma_q \) are real constants with unknown value.

One year later, Navarro [11] presented a symbolic computation package based on the object-oriented philosophy for manipulating matrices whose elements lie on the set of quasipolynomials of type (4). The kernel of the symbolic processor was developed in C++, defining a class for this new object as well as a set of functions that operate on the data structure: addition, subtraction, differentiation, and integration with respect to \( t \), substitution of an undetermined coefficient by a series, and many others. The goal of this processor is to provide a tool to solve a perturbed \( n \)-order differential equation of the class

\[ x^{(n)} + a_{n-1} x^{(n-1)} + \cdots + a_0 x = u(t) + \epsilon f(x, \dot{x}, \ldots, x^{(n-1)}), \]  

with initial conditions

\[ x(0) = x_{10}, \quad \dot{x}(0) = x_{20}, \ldots, x^{(n-1)}(0) = x_{n0}, \]  

where \( \epsilon \) is a small real parameter, \( a_0, a_1, \ldots, a_{n-1} \in \mathbb{R}, u(t) \) is a quasipolynomial, and \( f \) is such that

\[ f \left( x, \dot{x}, \ldots, x^{(n-1)} \right) = \sum_{0 \leq y_{1}, \ldots, y_{n-1} \leq M} f_{y_{1},\ldots,y_{n-1}} x_{y_{1}}^{(n-1)} \cdots x_{y_{n-1}}^{(n-1)} y_{n}, \]  

with \( M \in \mathbb{N}, y_{1}, \ldots, y_{n} \in \mathbb{N} \), and \( f_{y_{1},\ldots,y_{n-1}} \in \mathbb{R} \).

As a first step, Navarro and Pérez [12] have developed a symbolic technique for the computation of the principal matrix of the linear system associated with a homogeneous ordinary differential equation with constant coefficients of the form

\[ x^{(n)} + a_{n-1} x^{(n-1)} + \cdots + a_1 \dot{x} + a_0 x = 0, \]  

with \( a_0, a_1, \ldots, a_{n-1} \in \mathbb{R} \), with initial conditions

\[ x(0) = x_{10}, \quad \dot{x}(0) = x_{20}, \ldots, x^{(n-1)}(0) = x_{n0}, \]  

being \( x_{10}, \ldots, x_{n0} \in \mathbb{R} \). This method provides a final analytical solution which can be completely computed in a symbolic way.

The second step in the construction of the solution to (7) is to obtain a symbolic procedure for computing the solution to the nonhomogeneous equation

\[ x^{(n)} + a_{n-1} x^{(n-1)} + \cdots + a_1 \dot{x} + a_0 x = u(t), \]  

where, as above, \( u(t) \) is a quasipolynomial.

This new symbolic package can be useful for research and educational purposes in the field of differential equations or dynamical systems. Nowadays there are many open problems which requires massive symbolic computation as, to cite one example, the analytical theory of the resonant motion of Mercury. We would like to stress that the aim of this work is to develop a symbolic tool, not a numeric method, as numeric solutions cannot be used in perturbation methods for differential equations. However, we have performed comparisons between the symbolic solution with a numeric one, just to show the efficiency of the technique.

In next section, we summarize the scheme proposed in [12] to calculate the solution to (10), which is needed to express the solution to the complete problem (12). The technique to construct this solution will be described in Section 3.

## 2. Solution to the Homogeneous Problem

As mentioned, Navarro and Pérez [12] have proposed a symbolic method to compute the solution to (10)

\[ x^{(n)} + a_{n-1} x^{(n-1)} + \cdots + a_1 \dot{x} + a_0 x = 0, \]  

where \( a_0, a_1, \ldots, a_{n-1} \in \mathbb{R} \), with initial conditions

\[ x(0) = x_{10}, \quad \dot{x}(0) = x_{20}, \ldots, x^{(n-1)}(0) = x_{n0}, \]  

being \( x_{10}, \ldots, x_{n0} \in \mathbb{R} \). This method provides a final analytical solution which can be completely computed in a symbolic way.
2.1. Description of the Method. With the aid of the substitutions
\[ x_1 = x, x_2 = \dot{x}, \ldots, x_n = x^{(n-1)}, \]
(15) is transformed into the system of differential equations given by
\[ X(t) = AX(t), \quad X(0) = X_0, \]
(16) where A is the companion matrix,
\[
A = \begin{pmatrix}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
-a_0 & -a_1 & -a_2 & \cdots & -a_{n-1}
\end{pmatrix},
\]
(17)

To compute the exponential of A, the matrix is split into B + C, where
\[
B = \begin{pmatrix}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 0 \\
0 & 0 & 0 & \cdots & 0
\end{pmatrix},
\]
(18)
\[
C = \begin{pmatrix}
0 & 0 & 0 & \cdots & 0 \\
0 & 0 & 0 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 0 \\
-a_0 & -a_1 & -a_2 & \cdots & -a_{n-1}
\end{pmatrix},
\]
(19)

Then, we use the approximation
\[ e^A \approx (e^{B/m} e^{C/m})^m, \]
(20) with \( m \in \mathbb{N} \). This approach to obtain \( e^A \) is of potential interest when the exponentials of matrices B and C can be efficiently computed and requires \( a_{n-1} \) to be nonequal to zero. In our case,
\[
e^{B/m} = \begin{pmatrix}
g_0(m) & g_1(m) & g_2(m) & \cdots & g_{n-1}(m) \\
0 & g_0(m) & g_1(m) & \cdots & g_{n-2}(m) \\
0 & 0 & g_0(m) & \cdots & g_{n-3}(m) \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & g_0(m)
\end{pmatrix},
\]
(21)
\[
e^{C/m} = I - \frac{1}{a_{n-1}} (e^{-a_{n-1}/m} - 1) C
\]
(22)

being, for any \( n \in \mathbb{N} \),
\[ g_n(m) = \frac{1}{n!m^n}, \]
(23) and, for any \( i = 0, \ldots, n-2 \),
\[ \omega_i = \frac{a_i}{a_{n-1}} \left( e^{-a_{n-1}/m} - 1 \right), \quad \omega_{n-1} = e^{-a_{n-1}/m}. \]
(24)

As it is established in Moler and van Loan [13], for a general splitting \( A = B + C, m \) can be determined from
\[ \left\| e^A - \left( e^{B/m} e^{C/m} \right)^m \right\| \leq \frac{1}{2m} \|[B, C]\| e^{\|B|+|C|}. \]
(25)

Thus, with A being the companion matrix, we get that
\[ \left\| e^A - \left( e^{B/m} e^{C/m} \right)^m \right\| \leq \frac{1}{m} e^{1+|a|} \| a \|, \]
(26)
where \( a = (a_0, a_1, \ldots, a_{n-1}) \). Here,
\[ \|x\| = \|x\|_1 = |x_1| + \cdots + |x_n|, \]
(27)
for any \( x = (x_1, \ldots, x_n) \in \mathbb{R}^n \), and \( \|A\| = \max_{k=1:n} \|Ax\|_1 = \max_{i} (|a_{1,i}| + \cdots + |a_{n,i}|) \), for any matrix
\[
A = \begin{pmatrix}
a_{11} & a_{12} & \cdots & a_{1n} \\
a_{21} & a_{22} & \cdots & a_{2n} \\
\vdots & \vdots & \ddots & \vdots \\
a_{n1} & a_{n2} & \cdots & a_{nn}
\end{pmatrix},
\]
(28)

2.2. Adaptation to a Symbolic Formalism. Navarro and P´erez [12, 14] have proposed an adaptation of the method described above in order to compute the matrix \( e^A \) instead of \( e^B \). If we do so, we obtain the principal matrix of (16), whose elements lie on the set of quasipolynomials, and the symbolic processor results in being suitable to work with those matrices. The approach is to compute
\[ e^A = \left( e^{B/m} e^{C/m} \right)^m, \]
(29) taking into account that
\[
e^{B/m} = \begin{pmatrix}
g_0(t, m) & g_1(t, m) & \cdots & g_{n-1}(t, m) \\
0 & g_0(t, m) & \cdots & g_{n-2}(t, m) \\
0 & 0 & \cdots & g_{n-3}(t, m) \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & g_0(t, m)
\end{pmatrix},
\]
(30)
\[
e^{C/m} = I - \frac{1}{a_{n-1}} (e^{-a_{n-1}/m} - 1) C
\]
(31)
\[
e^{C/m} = \begin{pmatrix}
1 & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
a_0(t) & \omega_1(t) & \omega_2(t) & \cdots & \omega_{n-1}(t)
\end{pmatrix},
\]
(32)

being, for any \( n \in \mathbb{N} \),
\[ g_n(t, m) = \frac{t^n}{n!m^n}, \]
(33)
and, for any \( i = 0, \ldots, n-2 \),
\[
\omega_i(t) = \frac{a_i}{a_{n-1}} e^{-a_{n-1} t/m} - 1, \quad \omega_{n-1}(t) = e^{-a_{n-1} t/m}.
\] (30)

Thus, \( e^{A t} \) is a matrix of quasipolynomials that can be completely computed through the symbolic processor developed by Navarro [11]. The procedure for the computation of the exponential matrix is substantially simplified by using the following equation, which avoids the symbolic multiplication of \( e^{B t/m} \) and \( C_z^{i/m} \):
\[
e^{B t/m} e^{C_z^{i/m}} = e^{B t/m} + H(t,m),
\] (31)
where
\[
H(t,m) = \frac{1}{a_{n-1}} f(t,m) \begin{pmatrix} \vdots \\ \vdots \end{pmatrix} \begin{pmatrix} a_0 & a_1 & \cdots & a_{n-1} \end{pmatrix},
\]
\[
f(t,m) = e^{-a_{n-1} t/m} - 1.
\] (32)

This relation can be obtained directly from the multiplication of matrices \( e^{B t/m} \) and \( C_z^{i/m} \) as given in (28).

2.3. Symbolic Expansion of the Exponential Matrix. As it has been stated in Section 2.2, the exponential matrix \( e^{A t} \) can be symbolically calculated through (27) and (31)
\[
e^{A t} = (e^{B t/m} e^{C_z^{i/m}})^m = (e^{B t/m} + H(t,m))^m.
\] (33)

This expression can be calculated symbolically. Let us express \( H(t,m) \) as
\[
H(t,m) = \lambda(t,m) J(t,m),
\] (34)
with
\[
\lambda(t,m) = \frac{1}{a_{n-1}} f(t,m),
\]
\[
J(t,m) = \begin{pmatrix} \vdots \\ \vdots \\ g_0(t,m) \end{pmatrix} \begin{pmatrix} a_0 & a_1 & \cdots & a_{n-1} \end{pmatrix}.
\] (35)

Thus,
\[
(e^{B t/m} + H(t,m))^m = \sum_{k=0}^{m} k^m (t,m) e^{B t/m}, J(t,m))_k m_k,
\] (36)
where \((A, B)_k^m \) is the so-called noncommutative parenthesis, defined as
\[
(A, B)_k^m = \sum_{\sigma} \prod_{j=1}^{m} \left( A^{(1-\sigma(j)/2)B^{(1+\sigma(j)/2)}} \right)_{\sigma(j)},
\] (37)
where \( A \) and \( B \) are two noncommutative \( n \times n \) matrices, \( m, k, c_{ij} \in \mathbb{Z} \cup \{0\} \),
\[
\sigma(m,k) = \begin{cases} 2k + 1, & \text{if } 2k \leq m, \\ 2(m-k+1), & \text{if } 2k > m, \end{cases}
\] (38)
and \( c_{ij} \) is determined by the following properties:
\[
(1) \quad \sum_{j=1}^{\sigma(m,k)} c_{ij} = m \text{ for all } i = 1, 2, \ldots, \binom{m}{2};
\]
\[
(2) \quad \sum_{i=1}^{\lceil \sigma(m,k)/2 \rceil} c_{ij} = m - k \text{ for all } i = 1, 2, \ldots, \binom{m}{3};
\]
(3) \( c_{ij} \neq 0 \) for all \( i = 1, 2, \ldots, \binom{m}{2} \); (4) \( c_{ij} \neq 0 \) and \( c_{(j-2)k) \neq 0 \), then \( c_{(j+1)k} \neq 0 \) for all \( i = 1, 2, \ldots, \binom{m}{4} \) and \( j = 1, 2, \ldots, \sigma(m,k) - 2 \).

In the following, we summarize some expressions which simplify the way in which the matrix \( (e^{B t/m} + H(t,m))^m \) is symbolically computed. First, let us introduce the following matrices:
\[
S_{n-1}(t,m) = \begin{pmatrix} a_0 & a_1 & \cdots & a_{n-1} \end{pmatrix} F(t,m),
\]
\[
F(t,m) = \begin{pmatrix} t^{-1} 0 & 0 & \cdots & 0 \\ (n-1) t^{-2} & (n-2) t^{-2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ (n-1)! t^{-n} & (n-2)! t^{-n} & \cdots & 0 \end{pmatrix}.
\] (39)

Lemma 1. For any \( k \in \mathbb{Z} \) such that \( k > 1 \),
\[
(e^{B t/m})^k = \begin{pmatrix} G_{0,k}(t,m) & G_{1,k}(t,m) & \cdots & G_{n-1,k}(t,m) \\ 0 & G_{0,k}(t,m) & \cdots & G_{n-2,k}(t,m) \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & G_{0,k}(t,m) \end{pmatrix},
\] (40)
with
\[
G_{0,k}(t,m) = k^k g_0(t,m),
\] (41)
for each \( \nu = 0, \ldots, n-1 \), where \( g_\nu(t,m) \) is given by (29).

Lemma 2. For any \( p \in \mathbb{Z} \) such that \( p > 1 \),
\[
(H(t,m))^p = \left( \frac{f(t,m)}{a_{n-1} (n-1)! t^{n-1}} \right)^p (S_{n-1}(t,m))^{p-1} \times F(t,m) (a_0 \ a_1 \ \cdots \ a_{n-1}),
\] (42)
where \( S_{n-1}(t,m) \) and \( F(t,m) \) are given by (39).

Lemma 3. For any \( p, k \in \mathbb{Z} \) such that \( p, k \geq 1 \),
\[
(e^{B t/m})^k (H(t,m))^p = \left( \frac{f(t,m)}{a_{n-1} (n-1)! t^{n-1}} \right)^p (S_{n-1}(t))^{p-1} \times \Omega F(t,m) (a_0 \ a_1 \ \cdots \ a_{n-1}),
\] (43)
where $S_{n-1}(t, m)$ and $F(t, m)$ are given by (39), and

$$
\Omega = \begin{pmatrix}
(k+1)^{n-1} & 0 & \cdots & 0 \\
0 & (k+1)^{n-2} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 1
\end{pmatrix}.
$$

(44)

**Lemma 4.** For any $p, k \in \mathbb{Z}$ such that $p, k \geq 1$,

$$
H^p(t, m) \left(e^{B_t/m}\right)^k = \left(\frac{f(t, m)}{a_{n-1} (n-1)! m^{p-1}}\right)^p
\times (S_{n-1}(t))^{p-1} F(t, m) A(t, m),
$$

where $S_{n-1}(t, m)$ and $F(t, m)$ are given by (39),

$$
A(t, m) = (A_0(t, m) \ A_1(t, m) \cdots \ A_{n-1}(t, m)),
$$

$$
A_{\mu}(t, m) = \sum_{\nu=0}^{\mu} a_{\nu} k^{\nu} g_{\mu-\nu},
$$

(46)

for any $\mu = 0, \ldots, n-1$, and $g_{\nu}$ is given by (29).

For the sake of simplicity, we have omitted the dependence on $m$ and $t$ of $g_{\nu}$.

**3. Solution to the Nonhomogeneous Problem**

The general solution to a nonhomogeneous linear differential equation of order $n$ can be expressed as the sum of the general solution to the corresponding homogeneous, linear differential equation and any solution to the complete equation. The symbolic manipulation system calculates the solution to a nonperturbed differential equation with initial conditions of the form (12)

$$
x^{(n)} + a_{n-1} x^{(n-1)} + \cdots + a_1 \dot{x} + a_0 x = u(t),
$$

(47)

with initial conditions

$$
x(0) = x_20, \ldots, x^{(n-1)}(0) = x_{n0},
$$

(48)

where $a_0, a_1, \ldots, a_{n-1} \in \mathbb{R}$, and $x_20, \ldots, x_{n0} \in \mathbb{R}$, and

$$
u(t) = \sum_{n=0}^{\infty} r^n e^{\alpha t} \left(\lambda_y \cos(\omega_t) + \mu_y \sin(\omega_t)\right),
$$

(49)

being $n_y \in \mathbb{N}$, and $\alpha_y, \omega_y, \lambda_y, \mu_y \in \mathbb{R}$. With the aid of the substitutions

$$
x_1 = x, x_2 = \dot{x}, \ldots, x_n = x^{(n-1)},
$$

(50)

(12) is reduced to the system of differential equations given by

$$
\dot{X}(t) = AX(t) + B(t), \quad X(0) = X_0,
$$

(51)

where

$$
A = \begin{pmatrix}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
-a_0 & -a_1 & -a_2 & \cdots & -a_{n-1}
\end{pmatrix},
$$

$$
B(t) = \begin{pmatrix}
0 \\
\vdots \\
x_1(t) \\
x_2(t) \\
\vdots \\
x_n(t)
\end{pmatrix},
$$

$$
X(t) = \begin{pmatrix}
x_{10} \\
x_{20} \\
x_1(t) \\
x_2(t) \\
\vdots \\
x_n(t)
\end{pmatrix},
$$

(52)

$$
X_0 = \begin{pmatrix}
x_{10} \\
x_{20} \\
\vdots \\
x_{n0}
\end{pmatrix}.
$$

The computation of the solution to the constant coefficients linear part requires the calculation of the exponential of the matrix $A$, $\Phi(t) = e^{At}$:

$$
X(t) = \Phi(t) X_0 + \Phi(t) \int_0^t \exp(At) B(\tau) d\tau.
$$

(53)

**3.1. Symbolic Expansion of the Solution.** In the following, we give a formula for the symbolic expansion of the solution to the complete ordinary differential equation. To that end, let us express the noncommutative parenthesis $(e^{B_t/m}, J(t, m))^m$ as

$$
(e^{B_t/m}, J(t, m))^m = \begin{pmatrix}
p_{r_{11}}^{(m)}(t) & \cdots & p_{r_{1n}}^{(m)}(t) \\
\vdots & \ddots & \vdots \\
p_{r_{n1}}^{(m)}(t) & \cdots & p_{r_{nn}}^{(m)}(t)
\end{pmatrix} = (p_{r_{ij}}^{(m)}(t))_{i,j=1}^n = P(m, k)(t),
$$

(54)

where each $p_{r_{ij}}^{(m)}(t)$ is a polynomial of degree $r_{ij} \leq m(n-1)$ in the indeterminate $t$ with coefficients from $\mathbb{R}$, and $m \neq 0$.

Let us also express

$$
\lambda^k(t, m) = \left(\frac{1}{a_{n-1}} (e^{\alpha_{n-1} t/m} - 1)\right)^k = \sum_{\nu=0}^{k} \alpha_{\nu} e^{\beta_{\nu}},
$$

(55)

being

$$
\alpha_{\nu} = \left(\frac{1}{a_{n-1}}\right)^k \binom{k}{\nu} (-1)^{\nu},
$$

$$
\beta_{\nu} = \frac{a_{n-1}}{m} (k-\nu).
$$

(56)
Thus, taking into account (33), the exponential matrix of $A$ can be arranged as

$$e^{At} = \sum_{k=0}^{m} \left( \phi_k(t) P_{r_1}^{(m,k)}(t) \cdots \phi_k(t) P_{r_m}^{(m,k)}(t) \right)$$

where

$$\phi_k(t) = \sum_{y=0}^{k} \alpha_y e^{\beta_y t}.$$

In order to develop a symbolic expression of the solution to the complete differential equation, let us express $u(t)$ as

$$u(t) = e^{\delta t} (Q_a(t) \cos(\omega t) + T_b(t) \sin(\omega t)),$$

with $a, b \in \mathbb{Z} \cup \{0\}$, $\delta, \omega \in \mathbb{R}$, and $Q_a(t)$ and $T_b(t)$ being real polynomials of degrees $a$ and $b$, respectively, in the indeterminate $t$.

The product $e^{-At} B(\tau)$ can be arranged as follows:

$$e^{-At} B(\tau) = \left( \int_0^t \left( \sum_{k=0}^{m} \left( \sum_{y=0}^{k} \alpha_y e^{\beta_y \tau} \right) P_{r_1}^{(m,k)}(-\tau) \right) u(\tau) d\tau \right).$$

Here, the integrand of each element of the above matrix can be written in the form of a quasipolynomial. Hence, we arrive to the formulæ

$$\int_0^t \left( \sum_{k=0}^{m} \left( \sum_{y=0}^{k} \alpha_y e^{\beta_y \tau} \right) P_{r_1}^{(m,k)}(-\tau) \right) u(\tau) d\tau = \sum_{\alpha_n} \left( \eta_{\alpha_n} C_{\alpha_n \beta_n \gamma_n}(t) + \gamma_{\alpha_n} S_{\alpha_n \beta_n \gamma_n}(t) \right),$$

where $\alpha_n \in \mathbb{Z}^+ \cup \{0\}$, $\beta_n, \gamma_n \in \mathbb{R}$, $j = 1, \ldots, n$, and

$$C_{m,\beta,\gamma}(t) = \int_0^t m e^{\beta t} \cos(\gamma t) dt,$$

$$S_{m,\beta,\gamma}(t) = \int_0^t m e^{\beta t} \sin(\gamma t) dt.$$

These functions are computed recursively through

$$C_{0,\beta,\gamma}(t) = -\frac{\gamma}{\beta^2 + \gamma^2} e^{\beta t} \sin(\gamma t) + \frac{\beta}{\beta^2 + \gamma^2} e^{\beta t} \cos(\gamma t),$$

$$S_{0,\beta,\gamma}(t) = -\frac{\beta}{\beta^2 + \gamma^2} e^{\beta t} \sin(\gamma t) - \frac{\gamma}{\beta^2 + \gamma^2} e^{\beta t} \cos(\gamma t),$$

and, for any $m \geq 1$,

$$C_{m,\beta,\gamma}(t) = t^m C_{0,\beta,\gamma}(t) - m \frac{\gamma}{\beta^2 + \gamma^2} S_{m-1,\beta,\gamma}(t),$$

$$S_{m,\beta,\gamma}(t) = t^m S_{0,\beta,\gamma}(t) - m \frac{\beta}{\beta^2 + \gamma^2} C_{m-1,\beta,\gamma}(t) + m \frac{\gamma}{\beta^2 + \gamma^2} C_{m-1,\beta,\gamma}(t).$$

Thus, (53) can be expressed via a quasipolynomial and, thus, obtained through the designed symbolic system.

### 4. Symbolic and Numeric Results

#### 4.1. On the Form of the Exponential Matrix. The aim of this section is to illustrate the form that the approximation of the exponential matrix adopts. For that purpose, let us consider the differential equation given by

$$x^{(4)} + 4x + 3\ddot{x} + 2\dot{x} + x = 0,$$

with initial conditions

$$x(0) = 1, \quad \dot{x}(0) = 0, \quad \ddot{x}(0) = 0, \quad \dddot{x}(0) = 0.$$

This equation is transformed into the system of differential equations given by

$$\dot{X}(t) = AX(t),$$

where $A$ is the companion matrix

$$A = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -3 & -4 \end{pmatrix}. $$

According to the technique described in Section 2, we split matrix $A$ into $B + C$, where

$$B = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -3 & -4 \end{pmatrix},$$

$$C = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & -2 & -3 & -4 \end{pmatrix}. $$
Equation (36),

$$\left(e^{B t/m} + H(t, m)\right)^m = \sum_{k=0}^{m} \lambda^k(t, m) \left(e^{B t/m}, J(t, m)\right)_k^m,$$

(70)

allows us to compute a symbolic approximation to the solution to the differential equation. In the problem we are discussing, $e^{B t/m}, H(t, m), \lambda(t, m)$, and $J(t, m)$ can be written as

$$e^{B t/m} = \begin{pmatrix} 1 & \frac{t}{m} & \frac{t^2}{(2m)} & \frac{t^3}{(6m)} \\ 0 & 1 & \frac{t}{m} & \frac{t^2}{(2m)} \\ 0 & 0 & 1 & \frac{t}{m} \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

(71)

$$H(t, m) = \lambda(t, m) J(t, m),$$

with

$$\lambda(t, m) = \frac{1}{4} \left(e^{-t/m} - 1\right),$$

$$J(t, m) = \begin{pmatrix} \frac{t^3}{(6m^2)} & \frac{2t^3}{(6m^2)} & \frac{3t^3}{(6m^2)} & \frac{4t^3}{(6m^2)} \\ \frac{t^2}{(2m^2)} & \frac{2t^2}{(2m^2)} & \frac{3t^2}{(2m^2)} & \frac{4t^2}{(2m^2)} \\ \frac{t}{m} & \frac{2t}{m} & \frac{3t}{m} & \frac{4t}{m} \\ 1 & 2 & 3 & 4 \end{pmatrix}.$$  

(72)

Taking, for instance, $m = 3$, we get that

$$e^{A t} = \sum_{k=0}^{3} \lambda^k(t, 3) \left(e^{B t/3}, J(t, 3)\right)_k^3
\phi^3 + \phi \left(\phi^2 B + B \phi^2 + \phi B \phi\right)
+ \phi^2 \left(\phi B^2 + B \phi^2 + B \phi B + \phi B \phi\right) + \phi^3 B^3,$$

(73)

For the sake of simplicity, we have introduced the following notation:

$$\phi = e^{B t/3}, \quad B = J(t, 3).$$

The program proceeds as follows. The first window (Figure 2) allows us introducing the definition of variables, the order of the ODE and its coefficients, and the function of the nonhomogeneous term \(u(t)\).

The next window visualizes the expression of the companion matrix related to the ODE (Figure 3).

Then, matrices \(B\), \(\exp(Bl/m)\), \(C\), and \(\exp( Ct/m)\), which are used in the calculation of the exponential matrix, are
computed by using a value of $m$ satisfying (23). These matrices are presented in Figures 4, 5, 6, and 7.

In Figures 8 and 9, we evaluate the exponential matrix $e^{At}$ in $t = 1$ and for $m = 1000$. The algebraic processor enables us to change these two parameters. We should emphasize that the symbolic solution to the problem is dependent on the value of parameter $m$. We have computed this solution for different values of this parameter ($m = 10, 100, 1000$, and 10000). In Figures 10 and 11, we compare the real solution with symbolic solutions $x(t)$ for these values of $m$. We observe that the symbolic solution gets closer to the real solution as the value of $m$ is increased.

Table 1 shows the numerical evolution of the symbolic approximation $x_s(t)$, computed for $m = 1000$. These values have been obtained by substituting variable $t$ in the symbolic solution by values $0.1, 0.2, \ldots, 1$.

In Figure 12, we compare the symbolic approximation, computed via the symbolic processor, with the exact solution (87). We also compare these two functions with a numeric solution computed through a Runge-Kutta 4th order method with step $h = 0.1$. We see that the solution symbolically computed fits better to the exact solution than the described numerical solution. In Table 2, we show the error on the solution computed using both methods. We observe that error obtained in the symbolic approximation is quite smaller that the numeric one. This fact can be better observed in Figure 13, where we show the difference in absolute value between the exact solution and the symbolic and numeric solutions. Nevertheless, it is not the goal of this paper to develop a numeric tool. The symbolic technique we have developed provides an analytical solution which can be used

5. Conclusions

We have developed a symbolic processor as well as a symbolic technique in order to deal with the solution to a linear ordinary differential equation with constant coefficients of order $n$. The solution to this equation is computed completely in a symbolic way that is, the solution is expressed as a function of $t$. This function can be of great interest to face a perturbed differential equation by means of a perturbation method. The aim of this work is not to develop a numeric method. However, we have compared the symbolic solution obtained via our symbolic processor with a numeric solution computed with a Runge-Kutta method, in order to show how our solution is closer to the exact solution.
