By means of the function induced by a logical formula $A$, the concept of truth degree of the logical formula $A$ is introduced in the 3-valued pre-rough logic in this paper. Moreover, similarity degrees among formulas are proposed and a pseudometric is defined on the set of formulas, and hence a possible framework suitable for developing approximate reasoning theory in 3-value logic pre-rough logic is established.

1. Introduction

Rough set theory was proposed by Pawlak [1] in the 1980s of the last century to serve as an approximate description of sets which are unknown and incompletely specified. Its applications [2–8] have been found in fields such as data mining, learning, and approximate reasoning. Theoretical work [9–14] has included investigations of the logical, category-theoretic, topological, and algebraic aspects of rough sets.

It is undoubtedly that set theory and logic systems are strongly coupled in the development of modern logic. Scholars have been trying to build rough logic corresponding to rough set semantics since the birth of rough set theory. The notion of rough logic was initially proposed by Pawlak [9], and this work was followed by Orłowska and Vakarelov in a sequence of papers [15,16]. In [10], a formal logic system PRL corresponding to pre-rough algebra was proposed. In [17], Zhang and Zhu proposed a rough logic system RSL whose schematic is rough sets and extensional regular double Stone algebras.

The symbolic and formalism are characteristics in traditional mathematical logic, and the form reasoning of logic was studied mainly through the strict argument. But numerical computation aims to solve various computing problems by means of some mathematical methods and pays close attention to problem solving as well as to error estimation. Hence, mathematical logic and numerical computation are two branches of mathematics miles apart, and it seems that contact between them will not be built.

However, the contact of mathematical logic and numerical calculation is proposed by Wang and Zhou and how put numerical computation into mathematical logic is made a detailed study in his article that Quantitative Logic [18]. The theory of truth degrees of propositions in 2-valued propositional logic was proposed in [19]. In the following, the theory of truth degrees of Lukasiewicz system and other fuzzy logical systems is studied [20–23].

The basic idea of quantitative logic is to provide a graded approach to propositional logic. For example, $p$ is an atomic formula in 2-valued logic; that is, $p$ can choose two values, true and false. That is, $p$ has two valuations true and false, the valuation's sum is 2, and the number of the valuations which is true is 1, and then the ratio $1/2$ can describe the degree in which the atom formula $p$ is true in all valuations. We can describe each formula $A$ like this. For example, $p \land q$ is four kinds of valuations, and the number of the valuations which is true is 1, so the ratio $1/4$ can describe the degree in which the formula $p \land q$ is true in all valuations. For many-valued logic, we can like this use the ratio to describe the degree of a proposition which is true in all valuations, and we call the ratio the truth degree of a formula.

In the present paper, according to the method mentioned previously, we introduce a definition of truth degrees on 3-valued propositional pre-rough logic. We also study the
theory of truth degree and approximate reasoning theory in 3-valued pre-rough logic deeply.

The paper is organized as follows. After this introduction, in Section 2 we will introduce the basic content of pre-rough algebra and pre-rough logic in [10]. In Section 3, the theory of truth degree in 3-valued propositional pre-rough logic is built. In Section 4, the similarity degree and pseudodistance between two formulas are defined, and the continuity of operators based on pseudometrics is proven. In Section 5, a type of metric approximate reasoning theory in pre-rough logic based on the proposed pseudometrics is established. The final section offers the conclusion.

2. Pre-Rough Algebra and Pre-Rough Logic

Rough set theory begins with information systems (or information tables) and as an abstraction that are proposed. In general, approximation space is a pair \((U, R)\), where \(U\) is a nonempty set (the domain of discourse) and \(R\) is an equivalence relation on \(U\).

Let \((U, R)\) be an approximation space; if \(A \subseteq U\), the lower approximation \(\overline{R}A\) of \(A\) is the union of equivalence classes contained in \(A\), while its upper approximation \(\overline{R}A\) is the union of equivalence classes intersecting \(A\); that is,

\[
\overline{R}A = \bigcup \{[x] \mid [x] \subseteq A\},
\]

\[
\overline{R}A = \bigcup \{[x] \mid [x] \cap X \neq \emptyset\} = \{x \mid x \in U, [x] \cap A \neq \emptyset\},
\]

where \([x]\) denotes the equivalence class.

Then we call \(\overline{R}A(\overline{R}A)\) rough lower (upper) approximation of \(A\). A rough set \(A\) is termed definable in \((U, R)\) if and only if \(\overline{R}A = \overline{R}A\).

**Definition 1** (see [10]). A structure \(\mathcal{S} = (P, \leq, \sqcup, \sqcap, \neg, L, \rightarrow, 0, 1)\) is a pre-rough algebra if and only if

(1) \(P = (P, \leq, \sqcap, \sqcup, \neg, L, \rightarrow, 0, 1)\) is a bounded distributive lattice with least element 0 and largest element 1,

(2) \(\neg \neg a = a\),

(3) \(\neg(a \sqcup b) = \neg a \sqcap \neg b\),

(4) \(L a \leq a\),

(5) \(L(a \sqcap b) = La \sqcap Lb\),

(6) \(LLa = La\),

(7) \(L 1 = 1\),

(8) \(MLa = La\),

(9) \(\neg La \sqcup La = 1\),

(10) \(L(a \sqcup b) = La \sqcup Lb\),

(11) \(L a \leq Lb, Ma \leq Mb\) imply \(a \leq b\),

(12) \(a \rightarrow b = (\neg La \sqcup Lb) \cap (\neg Ma \sqcup Mb)\).

**Example 2.** Let \(\mathcal{S} = ((0, 1/2, 1), \leq, \sqcap, \sqcup, \neg, L, \rightarrow, 0, 1)\), where \(\leq\) is the usual order on real numbers and \(\sqcap\) and \(\sqcup\) are maximum and minimum, respectively: \(\neg 0 = 1, \neg 1/2 = 1/2, \neg 1 = 0, L0 = L(1/2) = 0,\) and \(L1 = 1\). Then it is a pre-rough algebra and is the smallest nontrivial pre-rough algebra.
Definition 4 (see [10]). A valuation \( v \) in pre-rough logic is a map from the set of rough formulas \( F(S) \) to any pre-rough algebra \( \mathcal{S} = (P, \leq, \cap, \cup, \neg, L, \to, 0, 1) \) satisfying, for all \( A, B \in F(S) \),
\[
  v(A \cap B) = v(A) \cap v(B), \quad v(LA) = L(v(A)), \quad v(\neg A) = \neg v(A).
\]
(3)
That is, \( v \) is a \((\neg, \cap, L)\) type homomorphism.

Remark 5. With \((\cup, \to, M)\) being defined by \((\neg, \cap, L)\), \( v \) is also \((\cup, \to, M)\) type homomorphism. That is, \( v(A \cup B) = v(A) \cup v(B), v(A \to B) = v(A) \to v(B), \) and \( v(MA) = M(v(A)) \).

Remark 6. From [10], pre-rough logic is sound and complete relative to the class of all pre-rough algebras. That is, for all \( A \in F(S), \Gamma \vdash A \) if and only if \( \Gamma \vdash A \), where \( \Gamma \) is a theory in pre-rough logic, \( \Gamma \vdash A \) means that \( A \) is a \( \Gamma \)-conclusion (i.e., \( A \) can be deduced from \( \Gamma \cup \{A\} \) within finite steps by using reasoning rules of pre-rough logic), and \( \Gamma \vdash A \) means that \( \Gamma \) entails \( A \) (i.e., \( A \) is satisfied by \( \Gamma \)).

3. The Theory of Truth Degree

Definition 7. Let \( T = \{0, 1/2, 1\} \) and define logical operations on \( T \) as follows: for all \( x, y \in T \), \( x \cap y = \min(x, y), x \cup y = \max(x, y), \) and \( x \to y = \{0, 1/2, 1\}, x \leq y \in \{0, 1/2, 1\} \). Then \( T \) is an algebra of type \((\cap, \cup, L, \to, \neg)\), which is called 3-valued pre-rough logic system, denoted by \( \mathcal{S} \).

A valuation of \( v: F(S) \to T \) is a homomorphism of type \((\neg, \cap, \cup, L, \to, \neg)\), and \( v(\neg A) \) is the valuation of \( A \) with respect to \( v \). The set consisting of all valuations of \( F(S) \) is denoted by \( \Omega_3 \).

Suppose that logic formula \( A(p_1, p_2, \ldots, p_n) \) contains \( n \) atomic formulas in \( F(S) \), and then \( A \) can induce a 3-value function \( f_A(x_1, x_2, \ldots, x_n): L^n \rightarrow L_A \), where \( f_A(x_1, x_2, \ldots, x_n) \) is making \( x_1, x_2, \ldots, x_n \) composed together by operators \( \neg, \cap, \) and \( L \), which is similar to the formula \( A(p_1, p_2, \ldots, p_n) \) that makes \( p_1, p_2, \ldots, p_n \) composed together by operators \( \neg, \cap, \) and \( L \). For example, a formula \( A = p \cap (q \to (r \lor \neg p)) \) can induce the function \( f_A(x_1, x_2, x_3) = x_1 \land (x_2 \to (x_3 \lor \neg x_1)), \) where \( x_1, x_2, \) and \( x_3 \) can be any value in \( L \). In this way, for each \( v \in \Omega_3, v(A) = f_A(v(p_1), v(p_2), \ldots, v(p_n)) \), so for each formula \( A \), we can induce a function \( f_A \) according to \( A \), which is called the induced function of \( A \). From the definition of tautology, we can get that if \( A \) is a tautology if and only if its induced function \( f_A(x_1, x_2, \ldots, x_n) \) is 1 holds for all \((x_1, x_2, \ldots, x_n) \in L_A^n \).

Definition 8. Let \( A(p_1, p_2, \ldots, p_n) \in F(S) \) contains \( n \) atomic formulas in 3-valued pre-rough logic system and let \( f_A(x_1, x_2, \ldots, x_n) \), be the induced function of \( A \), and then \( \tau(A) \) which is the truth degree of \( A \) is defined as
\[
  \tau(A) = \frac{1}{3^n} \left| f_A^{-1}(1) \right|,
\]
where \( \left| f_A^{-1}(1) \right| \) is the number of valuations satisfying \( f_A(v(p_1), v(p_2), \ldots, v(p_n)) = 1 \).

Remark 10. (i) Let \( A = A(p_1, p_2, \ldots, p_n) \in F(S) \), and for all \( v \in \Omega_3 \), we have \( v(MA) = 1 \) if and only if \( v(A) = 1 \), with solving \( \tau(A) \)
\[
  \tau(A) = \frac{1}{3^n} \left| f_A^{-1}(1) \right| = \frac{1}{3^n} \left( \left| f_A^{-1}(\frac{1}{2}) \right| + \left| f_A^{-1}(1) \right| \right).
\]
(5)
(ii) In the same way we can get the following:
\[
  \tau(A) = \frac{1}{3^n} \left| f_A^{-1}(1) \right| = \frac{1}{3^n} \left| f_A^{-1}(1) \right|.
\]
(6)
Remark 11. It is clear that \( 0 \leq \tau(A) = \tau(A) \leq \tau(A) \leq 1 \) holds for every \( A \in F(S) \). Moreover, logically equivalent formulas have the same truth degree.

Proposition 12. Let \( (\overline{\tau}, \overline{\tau}) \) be (upper, lower) truth degree. Then
(i) \( 0 \leq \tau(A) = \tau(A) \leq \tau(A) \leq 1 \),
(ii) \( \overline{\tau}(A) = \overline{\tau}(MA) = \overline{\tau}(LA) \),
(iii) \( \tau(A) = 1 \) if and only if \( A \) is a theorem in pre-rough logic;
\[
  \overline{\tau}(A) = 1 \] if and only if \( MA \) is a theorem in pre-rough logic,
\[
  \tau(A) = 1 \] if and only if \( LA \) is a theorem in pre-rough logic,
(iv) \( \tau(\neg A) = \tau(\neg A) = 1 - \tau(A) \),
(v) \( \overline{\tau}(MA) = \overline{\tau}(MA) \).
if \( \Gamma \vdash MA \to MB \), then \( \overline{\tau}(A) \leq \overline{\tau}(B), \)
if \( \Gamma \vdash LA \to LB \), then \( \overline{\tau}(A) \leq \overline{\tau}(B), \)
if \( \Gamma \vdash A \to B \), then \( \overline{\tau}(A) \leq \overline{\tau}(B), \overline{\tau}(A) \leq \overline{\tau}(B), \) and
\[
  \overline{\tau}(A) \leq \overline{\tau}(B),
\]
(vi) $\tau(\text{A} \cup B) = \tau(\text{A}) + \tau(B) - \tau(\text{A} \cap B)$,
$\tau(\text{A} \cup B) = \tau(\text{A}) \vee \tau(B) - \tau(\text{A} \cap B)$,
$\tau(\text{A} \cup B) = \tau(\text{A}) \wedge \tau(B) - \tau(\text{A} \cap B)$.

**Theorem 13** (truth degree of MP rules). Let $A, B, C \in F(S)$.

(i) If $\tau(A) \geq \alpha, \tau(A \rightarrow B) \geq \beta$, then $\tau(B) \geq \alpha + \beta - 1$.

(ii) If $\tau(\text{A}) \geq \alpha, \tau(\text{A} \rightarrow \text{B}) \geq \beta$, then $\tau(\text{B}) \geq \alpha + \beta - 1$.

(iii) If $\tau(A) \geq \alpha, \tau(A \rightarrow B) \geq \beta$, then $\tau(B) \geq \alpha + \beta - 1$.

**Proof.** (i) $\tau(A) = (1/3^n) \times |f^{-1}_A(1)| \geq \alpha$, and then $|f^{-1}_A(1)| \geq 3^n \cdot \alpha$.

If $\tau(A \rightarrow B) = (1/3^n) \times |f^{-1}_{A \rightarrow B}(1)| \geq \beta$, and then $|f^{-1}_{A \rightarrow B}(1)| \geq 3^n \cdot \beta$.

Let $X, Y = A \rightarrow B$.

Because $|f^{-1}_{X \cap Y}(1)| = |f^{-1}_X(1)| + |f^{-1}_Y(1)| - |f^{-1}_{X \cap Y}(1)| \geq 3^n \cdot \alpha + 3^n \cdot \beta - 3^n$.

So we should prove $|f^{-1}_{X \cap Y}(1)| \leq |f^{-1}_B(1)|$, with $X \cap Y = v(A \cap (A \rightarrow B)) = v(A \cap (\neg MA \cup MB) \cap (\neg LA \cup LB))$.

In order to make $v(X \cap Y) = 1$ hold, then $v(A \cap (\neg MA \cup MB) \cap (\neg LA \cup LB)) = 1$ should hold. That means, $v(A) = 1, v(MA \cup MB) = 1$, and $v(\neg LA \cup LB) = 1$ should hold. So it must be $\tau(\text{A}) = 1$ and $\tau(\text{B}) = 1$.

So, if $\tau(A \cap B) = 1$, then $\tau(A) = 1$ and $\tau(\text{B}) = 1$; from the above analysis we have $v(X) = 1$; that is, $|f^{-1}_A(1)| = |f^{-1}_{X \cap Y}(1)|$.

With $\tau(A \cap B \rightarrow B$ being in pre-rough logic, so we have $f^{-1}_{X \cap Y}(1) \leq f^{-1}_B(1)$; hence $|f^{-1}_{X \cap Y}(1)| \leq |f^{-1}_B(1)|$, and we get $|f^{-1}_B(1)| \geq 3^n \cdot \alpha + 3^n \cdot \beta - 3^n$, so $\tau(B) = |f^{-1}_B(1)|/3^n \geq \alpha + \beta - 1$ holds.

(ii) $\tau(\text{A} \rightarrow B) = \tau(M \rightarrow (A \rightarrow B)) = (1/3^n) \times |f^{-1}_{x(M \rightarrow A \rightarrow B)}(1)| = (1/3^n) \times |f^{-1}_{M \rightarrow A \rightarrow B}(1)| \geq 3^n \cdot \alpha$, and then $|f^{-1}_{M \rightarrow A \rightarrow B}(1)| \geq 3^n \cdot \alpha$.

Let $X = MA \cup Y = A \rightarrow B$.

Because $|f^{-1}_{M \rightarrow A \rightarrow B}(1)| = |f^{-1}_{M \rightarrow A}(1)| + |f^{-1}_{A \rightarrow B}(1)| - |f^{-1}_{M \rightarrow A \cap B}(1)| \geq 3^n \cdot \alpha + 3^n \cdot \beta - 3^n$.

So we should prove $|f^{-1}_{M \rightarrow A \cap B}(1)| \leq |f^{-1}_{M \rightarrow A}(1)|$.

With $A \cap B \rightarrow B$ in pre-rough logic, so we have $f^{-1}_{M \rightarrow A \cap B}(1) \leq f^{-1}_{M \rightarrow A}(1)$; hence $|f^{-1}_{M \rightarrow A \cap B}(1)| \leq |f^{-1}_{M \rightarrow A}(1)|$, and we get $|f^{-1}_{M \rightarrow A}(1)| \geq 3^n \cdot \alpha + 3^n \cdot \beta - 3^n$, so $\tau(MA \cup A \rightarrow B) = |f^{-1}_{M \rightarrow A}(1)|/3^n \geq \alpha + \beta - 1$ holds.

Corollary 14. Let $A, B, C \in F(S)$.

(i) If $\tau(A) = 1, \tau(A \rightarrow B) = 1$, then $\tau(B) = 1$.

(ii) If $\tau(A) = 1, \tau(A \rightarrow B) = 1$, then $\tau(B) = 1$.

(iii) If $\tau(A) = 1, \tau(A \rightarrow B) = 1$, then $\tau(B) = 1$.

**Theorem 15** (truth degree of HS rules). Let $A, B, C \in F(S)$.

(i) If $\tau(A \rightarrow B) \geq \alpha, \tau(B \rightarrow C) \geq \beta$, then $\tau(A \rightarrow C) \geq \alpha + \beta - 1$.

(ii) If $\tau(A \rightarrow B) \geq \alpha, \tau(B \rightarrow C) \geq \beta$, then $\tau(A \rightarrow C) \geq \alpha + \beta - 1$.

(iii) If $\tau(A \rightarrow B) \geq \alpha, \tau(B \rightarrow C) \geq \beta$, then $\tau(A \rightarrow C) \geq \alpha + \beta - 1$.

**Proof.** (i) $\tau(A \rightarrow B) = (1/3^n) \times |f^{-1}_{A \rightarrow B}(1)| \geq \alpha$, so $|f^{-1}_B(1)| \geq 3^n \cdot \alpha$.

\(\tau(B \rightarrow C) = (1/3^n) \times |f^{-1}_{B \rightarrow C}(1)| \geq \beta\), so $|f^{-1}_{B \rightarrow C}(1)| \geq 3^n \cdot \beta$.

So we should prove $|f^{-1}_{A \rightarrow B}(1)| \leq |f^{-1}_{B \rightarrow C}(1)|$.

Let $E = f^{-1}_{A \rightarrow B} = \{v \in \Omega_i | v(\neg MA \cup MB) \cap (\neg LA \cup LB) = 1\}$, $F = f^{-1}_{B \rightarrow C} = \{v \in \Omega_i | v(\neg MB \cup MC) \cap (\neg LA \cup LC) = 1\}$, and $G = f^{-1}_{A \rightarrow C} = \{v \in \Omega_i | v(\neg MA \cup MC) \cap (\neg LA \cup LC) = 1\}$.

Let $E \subseteq E, F \subseteq F, G \subseteq G, (i = 1, 2), E_1 = \{v \in \Omega_1 | v(\neg MA \cup MB) = 1\}, F_1 = \{v \in \Omega_1 | v(\neg MB \cup MC) = 1\}, F_2 = \{v \in \Omega_2 | v(\neg LA \cup LC) = 1\}, G_1 = \{v \in \Omega_2 | v(\neg MA \cup MC) = 1\}, G_2 = \{v \in \Omega_2 | v(\neg LA \cup LC) = 1\}$.

Let $E \in F \cap F$, then $x \in E, F \subseteq F$ in the following two cases.

Case 1. Let $x \in \{v \in \Omega_1 | v(\neg LB) = 1\}$, and then we can get $x \in \{v \in \Omega_1 | v(MB) = 1\}$, with $x \in E_1$, so $x \in \{v \in \Omega_1 | v(\neg MC) = 1\}$, that is, $x \in G_1$; with $x \in F_1$, $x \in \{v \in \Omega_1 | v(\neg LA) = 1\}$, that is, $x \in G_2$. Hence $x \in G_1 \cap G_2 = G$.

Case 2. Let $x \notin \{v \in \Omega_1 | v(\neg LB) = 1\}$, in this case we prove $E \cap F \subseteq F$ in the following two cases.

(1) If $x \in \{v \in \Omega_1 | v(MB) = 1\}$, with $x \in E_1$, so $x \in \{v \in \Omega_1 | v(\neg MC) = 1\}$, that is, $x \in G_1$; with $x \in E_2$, $x \in \{v \in \Omega_1 | v(\neg LA) = 1\}$, that is, $x \in G_2$. Hence $x \in G_1 \cap G_2 = G$.

(2) If $x \notin \{v \in \Omega_1 | v(MB) = 1\}$, with $x \in E_2$, so $x \in \{v \in \Omega_1 | v(\neg MA) = 1\}$, that is, $x \in G_1$; with $x \in E_2$, $x \in G_2$. Hence $x \in G_1 \cap G_2 = G$.

So we have $E \cap F \subseteq G \Rightarrow |E \cap F| \leq |G|$.

With $|E| + |F| = |E \cup F| + |E \cap F|$ and $|E \cup F| \leq 3^n$, we can get
\[|E| + |F| = |E \cup F| + |E \cap F| \leq 3^n + |G|.
\]
Corollary 16. Let $A, B, C \in F(S)$. If $\tau(A \rightarrow B) = 1$, then $\tau(A \rightarrow C) = 1$.

4. Similarity Degree and a Pseudometric among Formulas

Definition 17. Suppose that $A, B \in F(S)$. Let

$$\xi(A, B) = \tau((A \rightarrow B) \cap (B \rightarrow A)),$$

(8)

$$\xi(A, B) = \tau((MA \rightarrow MB) \cap (MB \rightarrow MA)),$$

(9)

$$\xi(A, B) = \tau((LA \rightarrow LB) \cap (LB \rightarrow LA)).$$

(10)

Then one calls $\xi(A, B)$ the upper, lower similarity degree between $A$ and $B$.

Example 18. Let $A = p, B = q$, where $p, q$ are different atomic formulas, and calculate $\xi(A, B), \xi(A, B), \xi(A, B)$.

Solution 1. Consider

$$\xi(A, B) = \xi(p, q) = \tau((p \rightarrow q) \cap (p \rightarrow q))$$

$$= \frac{1}{3^2} \cdot \left| f^{-1}_{\xi(p, q) \cap (q \rightarrow p)}(1) \right|.$$ 

(11)

With $f^{-1}_{\xi(p, q) \cap (q \rightarrow p)}(1) = \{(0, 0), (1/2, 1/2), (1, 1)\}$, so $\xi(A, B) = 3/3^2 = 1/3$. Consider

$$\xi(A, B) = \xi(p, q) = \tau((Mp \rightarrow Mq) \cap (Mq \rightarrow Mp))$$

$$= \frac{1}{3^2} \cdot \left| f^{-1}_{\xi(Mp \rightarrow Mq) \cap (Mq \rightarrow Mp)}(1) \right|.$$ 

(12)

With $f^{-1}_{\xi(Mp \rightarrow Mq) \cap (Mq \rightarrow Mp)}(1) = \{(0, 0), (1/2, 1/2), (1, 1)\}$, so $\xi(A, B) = 5/3^2 = 5/9$. Similarly, we can obtain $\xi(A, B) = 5/9$.

Proposition 19. Suppose that $A, B, C \in F(S)$, and then

(i) $\xi(A, B) = \xi(MA \rightarrow MB), \xi(A, B) = \xi(LA \rightarrow LB),$

(ii) $\xi(A, B) = 1$ if and only if $\vdash A \rightarrow B$,

$$\xi(A, B) = 1$$ if and only if $\vdash MA \rightarrow MB$,

$$\xi(A, B) = 1$$ if and only if $\vdash LA \rightarrow LB$,

(iii) $\xi(A, B) + \xi(B, C) \leq \xi(A, C) + 1$,

$$\xi(A, B) + \xi(B, C) \leq \xi(A, C) + 1,$$

$$\xi(A, B) + \xi(B, C) \leq \xi(A, C) + 1,$$

(iv) $\xi(A, B) = 0$ if and only if $\vdash MA \rightarrow MB$,

$$\xi(A, B) = 0$$ if and only if $\vdash LA \rightarrow LB$,

(v) $\xi(A, B) = \xi(B, A), \xi(A, B) = \xi(B, A), \xi(A, B) = \xi(B, A)$.

Proof. The proof of (i), (ii), and (v) is obvious; we only give the proof of (iii) and (iv).

(iii) In general, assume that $A, B, C$ have the same atomic formulas $p_1, \ldots, p_n$. Then $E \cap F \subseteq G$, we have $|E| + |F| = |E \cup F| + |E \cap F| \leq 3^n + |G|$, that is,

$$|f^{-1}_E \cap (A \rightarrow B) + |f^{-1}_E \cap (B \rightarrow C)| \leq 3^n + |G|.$$ 

(13)

Hence, $\xi(A, B) + \xi(B, C) \leq \xi(A, C) + 1$.

The proof of the other inequalities can be obtained in a similar way.

(iv) From (9), we can get $\overline{\xi}(A, B) = 0$ if and only if $\vdash MA \rightarrow MB$.

Definition 20. Suppose that $A, B \in F(S)$, and $A$ and $B$ are said to be similar if $\overline{\xi}(A, B) = 1$.

Definition 20 gives a similarity relation in $F(S)$, and we can easily get the following corollary from Proposition 19.

Corollary 21. The similarity relation among formulas is an equivalent relation.

Proposition 22. Suppose that $A, B, A', B' \in F(S)$ and $\xi(A, A') \geq \alpha, \xi(B, B') \geq \beta$, and then

$$\xi(A \rightarrow B, A' \rightarrow B') \geq \alpha + \beta - 1.$$ 

(14)

Proof. Let $C = (A' \rightarrow A) \rightarrow ((A \rightarrow B) \rightarrow (A' \rightarrow B))$, which is a tautology in 3-valued pre-rough logic and hence $\tau(C) = 1$. Moreover, $\tau(A' \rightarrow A) \geq \xi(A, A') \geq \alpha$, and hence it follows from Theorem 13(i) that $\tau(A \rightarrow B) \rightarrow (A' \rightarrow B) \geq \alpha + 1 - 1 = \alpha$. Similarly, $\tau(A' \rightarrow B) \rightarrow (A \rightarrow B) \geq \alpha$. It follows that $\overline{\xi}(A \rightarrow B, A' \rightarrow B) \geq \alpha$. On the other hand, it
can be proved from \( \xi(B, B') \geq \beta \) that \( \xi(A' \rightarrow B, A' \rightarrow B') \geq \beta \). From Proposition 19(iii) \( \xi(A \rightarrow B, A' \rightarrow B') \geq \alpha + \beta - 1 \) holds.

**Definition 23.** Define three nonnegative functions \( \rho, \overline{\rho}, \rho : F(S) \times F(S) \rightarrow [0, 1] \) as follows: for all \( A, B \in F(S) \),

\[
\rho(A, B) = 1 - \xi(A, B), \\
\overline{\rho}(A, B) = 1 - \overline{\xi}(A, B), \\
\rho(A, B) = 1 - \xi(A, B).
\]

Then \( \rho, \overline{\rho}, \rho \) is called the pseudometrics on the set of rough formulas in pre-rough logic.

**Proposition 24.** Let \( \rho, \overline{\rho}, \rho \) be the three nonnegative functions defined in the above definition, and then for all \( A, B \in F(S) \)

\[
(1) \quad \rho(A, A) = \overline{\rho}(A, A) = \rho(A, A) = 0.
\]

\[
(2) \quad \rho(A, B) = \rho(B, A), \\
\overline{\rho}(A, B) = \overline{\rho}(B, A), \\
\rho(A, B) = \rho(B, A).
\]

\[
(3) \quad \rho(A, C) \leq \rho(A, B) + \rho(B, C), \\
\overline{\rho}(A, C) \leq \overline{\rho}(A, B) + \overline{\rho}(B, C), \\
\rho(A, C) \leq \rho(A, B) + \rho(B, C).
\]

**Theorem 25.** The operators \( \neg, \land, \lor \) are continuous on \( F(S), \rho \).

**Proof.** Suppose that \( A, B \in F(S), \varepsilon > 0 \), and \( \rho(A, B) < \varepsilon \), and then \( \rho(\neg A, \neg B) = 1 - \xi(\neg A, \neg B) = 1 - \tau((\neg A \rightarrow \neg B) \cap \neg (\neg B \rightarrow \neg A)) = 1 - \tau((\neg A \rightarrow \neg B) \cap \neg (\neg B \rightarrow \neg A)) = 1 - \xi(A, B) = \rho(A, B) < \varepsilon \). Hence \( \neg : F(S) \rightarrow F(S) \) is continuous.

Similarly, suppose that \( A, B \in F(S), \varepsilon > 0 \), and \( \rho(A, B) < \varepsilon \), then \( \rho(LA, LB) = 1 - \xi(LA, LB) = 1 - \tau((LA \rightarrow LB) \cap (LB \rightarrow LA)) = 1 - \tau((A \rightarrow B) \cap (B \rightarrow A)) = 1 - \xi(A, B) \leq \rho(A, B) \leq \varepsilon \). Hence \( L : F(S) \rightarrow F(S) \) is continuous.

**5. Approximate Reasoning in 3-Valued Propositional Pre-Rough Logic**

**Definition 27.** Let \( \Gamma \subset F(S) \), for all \( A \in F(S), \varepsilon > 0 \), if \( \rho(A, D(\Gamma)) = \inf\{\rho(A, B) : B \in D(\Gamma)\} < \varepsilon \), then \( \rho(A, D(\Gamma)) = \inf\{\rho(A, B) : B \in D(\Gamma)\} < \varepsilon \). Then we call \( \Gamma \) an approximate rough (upper, lower) consequence of \( \Gamma \) with I-type error less than \( \varepsilon \), respectively. Denoted by \( A \in D(\Gamma), A \in \overline{D}(\Gamma), \) and \( A \in D(\Gamma) \) each other.

**Definition 28.** Let \( \Gamma \subset F(S) \), for all \( A \in F(S), \varepsilon > 0 \), if \( 1 - \sup\{\tau(B \rightarrow A) : B \in D(\Gamma)\} < \varepsilon \), then we call \( \Gamma \) an approximate rough (upper, lower) consequence of \( \Gamma \) with II-type error less than \( \varepsilon \), respectively. Denoted by \( A \in D(\Gamma), A \in \overline{D}(\Gamma) \) each other.

**Definition 29.** Let \( \Gamma \subset F(S) \), for all \( A \in F(S), \varepsilon > 0 \), if \( \inf\{\tau(B \rightarrow A) : B \in D(\Gamma)\} < \varepsilon \), then we call \( \Gamma \) an approximate rough (upper, lower) consequence of \( \Gamma \) with III-type error less than \( \varepsilon \), respectively. Denoted by \( A \in D(\Gamma), A \in \overline{D}(\Gamma) \) each other, and \( H \) is Hausdorff distance.

Where \( (X, \rho) \) is a metric space, \( U \) and \( V \) are nonempty subsets on \( X \).

Let \( \rho(x, v) = \inf\{\rho(x, y) : y \in V\}, \overline{\rho}(x, v) = \inf\{\overline{\rho}(x, y) : y \in V\} \), \( H^*(U, V) = \sup\{\rho(x, v) : x \in U\}, H^*(U, V) = \sup\{\rho(x, v) : x \in U\} \),

\[
H^*(U, V) = \sup\{\rho(x, v) : x \in U\}, H(U, V, U) = \max(H^*(U, V), H^*(V, U)), \overline{H}^*(U, V) = \max(H^*(U, V), H^*(V, U)), \overline{H}(U, V) = \max(H^*(U, V), H^*(V, U)).
\]

**Theorem 30.** Let \( \Gamma \subset F(S), \) for all \( A \in F(S), \varepsilon > 0 \), and then

\[
(i) \quad A \in D(\Gamma) \text{ if and only if } A \in \overline{D}(\Gamma), \\
(ii) \quad A \in D(\Gamma) \text{ if and only if } A \in \overline{D}(\Gamma), \\
(iii) \quad A \in D(\Gamma) \text{ if and only if } A \in \overline{D}(\Gamma).
\]

**Proof.** (i) Let \( A \in D(\Gamma) \), and then we can get \( \rho(A, D(\Gamma)) = \inf\{\rho(A, B) : B \in D(\Gamma)\} < \varepsilon \), for \( \rho(A, D(\Gamma)) = \inf\{\rho(A, B) : B \in D(\Gamma)\} \leq \inf\{\rho(A, A \cup B) : B \in D(\Gamma)\} = \inf\{1 - \xi(A, A \cup B) : B \in D(\Gamma)\} = \inf\{1 - \tau((A \rightarrow A) \cap (A \rightarrow B))\} = 1 - \sup\{\tau(B \rightarrow A) : B \in D(\Gamma)\} < \varepsilon \), so \( A \in D(\Gamma) \).

Let \( A \in D(\Gamma) \), and then we can get \( 1 - \sup\{\tau(B \rightarrow A) : B \in D(\Gamma)\} < \varepsilon \), namely \( \sup\{\tau(B \rightarrow A) : B \in D(\Gamma)\} > 1 - \varepsilon \).

For \( \sup\{\tau(B \rightarrow A) : B \in D(\Gamma)\} \geq \sup\{\tau(B \rightarrow A) \cap (A \rightarrow B) : B \in D(\Gamma)\} > 1 - \varepsilon \), so \( A \in D(\Gamma) \).
In conclusion, $A \in D^1_\varepsilon(\Gamma)$ if and only if $A \in D^3_\varepsilon(\Gamma)$ is established.

The proof of (ii) and (iii) can be in a similar way as that of (i).

**Theorem 31.** Let $\Gamma \subseteq F(S)$, for all $A \in F(S)$, $\varepsilon > 0$, and then

(i) if $A \in D^3_\varepsilon(\Gamma)$, then $A \in D^1_\varepsilon(\Gamma)$;

(ii) if $A \nsubseteq D^3_\varepsilon(\Gamma)$, then $A \nsubseteq D^1_\varepsilon(\Gamma)$;

(iii) if $A \in D^3_\varepsilon(\Gamma)$, then $A \in D^1_\varepsilon(\Gamma)$.

**Proof.** (i) Let $A \in D^3_\varepsilon(\Gamma)$, and we can get inf $\{H(D(\Gamma), D(\Sigma)) | \Sigma \subseteq F(S), \Sigma \vdash A \} = \varepsilon$, so there exists $\Sigma \subseteq F(S)$ makes $\Sigma \vdash A$ and $H(D(\Gamma), D(\Sigma)) = \varepsilon$ hold. At the same time $A \in D(\Sigma)$, $\rho(A, D(\Gamma)) \leq H(D(\Gamma), D(\Sigma)) = \varepsilon$.

Hence we can get $A \in D^1_\varepsilon(\Gamma)$.

The proof of (ii) and (iii) can be in a similar way as that of (i).

**6. Conclusion**

Through the basic method of quantitative logic, the theory of truth degree in 3-valued pre-rough logic is studied in this paper. Moreover, similarity degrees among formulas are proposed and a pseudometric is defined thereon the set of formulas, and hence a possible framework suitable for developing approximate reasoning theory in 3-valued pre-rough logic is established.

It is worthy to notice that the results obtained in the present paper are based on the assumption that the probabilities involved are evenly distributed, while it may happen in real life that some propositions are considered more important than others and hence should be endowed with higher probabilities. Therefore, how to combine the method of probability logic is an attractive research topic, and we can find paper [21, 22] have give a possible way combine fuzzy logic and probability logic.
