This paper studies the indefinite stochastic LQ control problem with quadratic and mixed terminal state equality constraints, which can be transformed into a mathematical programming problem. By means of the Lagrangian multiplier theorem and Riesz representation theorem, the main result given in this paper is the necessary condition for indefinite stochastic LQ control with quadratic and mixed terminal equality constraints. The result shows that the different terminal state constraints will cause the endpoint condition of the differential Riccati equation to be changed. It coincides with the indefinite stochastic LQ problem with linear terminal state constraint, so the result given in this paper can be viewed as the extension of the indefinite stochastic LQ problem with the linear terminal state equality constraint. In order to guarantee the existence and the uniqueness of the linear feedback control, a sufficient condition is also presented in the paper. A numerical example is presented at the end of the paper.

1. Introduction

Linear quadratic (LQ) control is an extremely important class of control problems in both theory and application. It is pioneered by Kalman [1] for deterministic systems and was extended to stochastic systems by Wonham [2]. In recent years, extensive research has been carried out in the so-called indefinite stochastic LQ control, in which the cost weighting matrices are allowed to be indefinite; refer to [3–6] for detailed accounts. A basic assumption in the LQ theory, both for deterministic and stochastic cases, is that the variable is unconstrained except for the differential equations constraint. As far as we know, very few results for constrained deterministic LQ can be found compared with the unconstrained one, not to mention the stochastic LQ control [7]. While in many real applications, constrained LQ control problem (such as nonnegativity and bound constraints for state and control variables) is a well-posed problem, constrained stochastic LQ control problem has a concrete application background, but the conventional LQ approach would collapse in the presence of any constraints. Study on the constrained stochastic LQ control will contribute to both theory and application a lot.

Huang and Zhang [8] studied the indefinite stochastic LQ control problem with linear terminal state equality constraints. Necessary and sufficient conditions for indefinite stochastic LQ control problems were investigated based on the Lagrangian multiplier theorem and Riesz representation theorem. The result showed that the linear feedback optimal control can be obtained by solving systems of algebraic and differential equations. The previous results on unconstrained indefinite stochastic LQ can be viewed as a specified case of the main theorem in that paper.

This paper studied the indefinite stochastic LQ control problem with quadratic terminal equality constraints and mixed constraints, which can be viewed as the extension of [8]. When the terminal state constraint is quadratic, the feasible region defined by the terminal constraint is nonconvex and multiple local minima abound, which makes the problem more complex to locate the optimum consistently. Developing a deeper understanding of the problems, as well as efficient algorithms for solving them, will have a big impact in many applications. Another reason for the study of this problem is that the methods used for solving this type of problem can be used to solve more

general constrained optimal control problems. By means of the Lagrangian multiplier theorem and Riesz representation theorem, the main result in this paper is the necessary condition for indefinite stochastic LQ control with quadratic terminal constraints and mixed terminal constraints. The result showed that the difference of the terminal state constraints will cause the endpoint condition to be changed in the differential equations we obtained for the linear constraint control problem, which coincides with the reality. In order to guarantee the existence and the uniqueness of the linear feedback control, a sufficient condition is also presented in the paper. Numerical example is presented at the end of this paper.

For the convenience, we make use of the following basic notation in this paper. R^n is the n -dimensional real column vector, $x(t) = (x_1(t), \dots, x_n(t))'$ is the n -dimensional state column vector, $u(t) \in R^m$ is the control input vector, $\omega(\cdot)$ is the one-dimensional Brownian motion defined on filtered probability $(\Omega, F, P; F_t)$ with a standard F_t -adapted on $[0, T]$, and $F_t = \sigma(\omega(s) : 0 \leq s \leq t \leq T)$ is an information fluid produced by Brownian motion. $u(t)$ belongs to the admissible control set $U_{ad} = \{u(t) \in R^m, u(t) \in L_F^2(0, T; R^m)\}$ is the adapted stochastic process which satisfies $E \int_0^T |u^2(t)| dt < +\infty$ and the corresponding $x(t)$ satisfies (3), ξ_i is the given F_T measurable, integrable random variable; that is, $E(\xi_i) < +\infty$, and $i = 1, 2, \dots, l + q$ is a known number. $A, C \in L^\infty(0, T; S^{n \times n})$, $Q \in L^\infty(0, T; S^{n \times n})$, $B, D \in L^\infty(0, T; R^{n \times m})$, $R \in L^\infty(0, T; S^{m \times m})$, $R^{m \times m}$ is m row n column matrix, and $S^{n \times n}$ is an $n \times n$ symmetric matrix. $M_l \in R^{l \times n}$ is the terminal state linear constraint coefficient matrix, and $M_q \in R^{q \times n}$ is the terminal state quadratic constraint matrix. Two assumptions are given in this paper.

H_1 : M_l, M_q (the coefficient matrix for terminal linear and quadratic constraints respectively in Problem 1 to Problem 21) are full row rank and the set defined by the terminal state constraints is not empty;

H_2 : $L^\infty(0, T; X) := \{f(t) : f(t) \text{ is an } F_t\text{-adapted, } X\text{-valued measurable process on } [0, T], \text{ and } E \int_0^T \|f(t)\|_X^2 dt < +\infty\}$.

The rest of this paper is organized as follows. Section 2 gives the problem statement and some preliminaries, Section 3 presents the main results of this paper. Numerical example is given in Section 4. Finally, Section 5 concludes this paper.

2. Problem Statement and Preliminaries

Problem 1. We study the following indefinite stochastic LQ control problem:

$$\inf \left\{ J(x_0, u) := E \int_0^T x' Q x + u' R u dt \right\} \quad (1)$$

s.t.

$$\begin{aligned} dx(t) = & (A(t)x(t) + B(t)u(t)) \\ & + (C(t)x(t) + D(t)u(t)) d\omega(t), \end{aligned} \quad (2)$$

$$x(0) = x_0,$$

$$\begin{aligned} m_{11}x_{11}^2(T) + m_{12}x_{12}^2(T) + \dots + m_{1n}x_{1n}^2(T) &= \xi_1, \\ m_{21}x_{21}^2(T) + m_{22}x_{22}^2(T) + \dots + m_{2n}x_{2n}^2(T) &= \xi_2, \end{aligned} \quad (3)$$

$\vdots$

$$m_{q1}x_{q1}^2(T) + m_{q2}x_{q2}^2(T) + \dots + m_{qn}x_{qn}^2(T) = \xi_q.$$

Suppose that the feasible set defined by the quadratic constraint is not empty. We investigate the necessary condition under the linear feedback optimal control

$$u(t) = K(t)x(t), \quad (4)$$

in which $K(t) \in C^{m \times n}[0, T]$. The cost weight matrix in Problem 1 is not necessarily positive, which usually causes Problem 1 to be called indefinite stochastic LQ control problem with terminal constraint. First, we present some definitions and lemmas that will be used and then transform the optimal control Problem 1 into a deterministic control problem.

Definition 2 (Gateaux differential). Let X be a vector space, let Y be a normed space, and let T be a (possibly nonlinear) transformation defined on a domain $D \subseteq X$ with a range $R \subseteq Y$. Given $x \in D \subset X$, and h is an arbitrary vector in X . If the limit

$$\delta T(x; h) = \lim_{\alpha \rightarrow 0} \frac{1}{\alpha} [T(x + \alpha h) - T(x)] \quad (5)$$

exists, then it is called Gateaux differential at x with an increment h . If the limit exists for arbitrary $h \in X$, the transformation T is called Gateaux differentiable at x .

Definition 3 (Frechet differential). Let X and Y be normed linear spaces and let T be a transformation defined on an open domain $D \subset X$ with a range $R \subset Y$. If, for a fixed $x \in D \subset X$, there exist $\delta T(x; h) \in Y$, which is linear and continuous with respect to h such that

$$\lim_{\|h(t)\| \rightarrow 0} \frac{\|T(x + h) - T(x) - \delta T(x; h)\|}{\|h(t)\|} = 0, \quad (6)$$

then T is said to be Frechet differentiable at x , and $\delta T(x; h)$ is said to be the Frechet differential of T at x with an increment h .

Definition 4 (Frechet derivative and continuously Frechet differentiable). Suppose that a transformation T defined on an open domain $D \subset X$ is Frechet differentiable on D . The Frechet differential $\delta T(x; h) = T'(x)h$ for a fixed $x \in D$, where $T'(x)$ is a bounded linear operator from X to Y , one calls $T'(x)$ the derivative of $T(x)$. If the derivative $T'(x)$ is continuous on some open ball S , then T is continuously Frechet differentiable on S .

Definition 5 (regular point of transformation). Let $T(x)$ be a transformation defined on a Banach space X with a range Y ,

which is also a Banach space. $T(x)$ is continuously Frechet differentiable if, for a given $x_0 \in X$, $\delta T(x_0; h)$ is an onto mapping from X onto Y ; then x_0 is called a regular point.

Considering Problem 1 under the linear feedback optimal control, substituting $u(t)$ in Problem 1 with

$$u(t) = K(t)x(t). \quad (7)$$

And taking the place of $u(t)$ in (2), we have

$$dx = (A + BK)xdt + (C + DK)x d\omega. \quad (8)$$

According to the Itô integrals formula for xx' , in which $x(t)$ is the solution of (8), we have

$$d(xx') = [(A + BK)xx' + xx'(A + BK)' + (C + DK)xx'(C + DK)'] dt. \quad (9)$$

Define $E(xx') = X$; it is obvious that X is a symmetric matrix. Integrate both sides of (9) from 0 to t with variable t , then compute the derivatives of both sides of (9) after taking the expectation, then get the following matrix differential equation with the initial condition:

$$\begin{aligned} \dot{X} &= (A + BK)X + X(A + BK)' \\ &\quad + (C + DK)X(C + DK)', \\ X(0) &= X_0 = x_0 x_0'. \end{aligned} \quad (10)$$

Substituting $u(t)$ with $u(t) = K(t)x(t)$ in (1) to

$$\inf \left\{ J(X, K) = \text{tr} \int_0^T [QX(t) + K'(t)RK(t)X(t)] dt \right\}, \quad (11)$$

("tr" is the trace of a matrix, $E(\xi_i) = l_i$, $i = 1, 2, \dots, q$), the quadratic constraints are

$$\text{tr}(Q_1 X(T)) = l_1, \text{tr}(Q_2 X(T)) = l_2, \dots, \text{tr}(Q_q X(T)) = l_q, \quad (12)$$

where $Q_i = \text{diag}[m_{i1}, m_{i2}, \dots, m_{in}]$, $i = 1, 2, \dots, q$, and $L = (l_1, l_2, \dots, l_q)'$. Then Problem 1 can be transformed into the following deterministic optimal control Problem 6.

Problem 6. Consider

$$\inf \left\{ J(X, K) = \text{tr} \int_0^T [QX(t) + K'(t)RK(t)X(t)] dt \right\} \quad (13)$$

s.t.

$$\begin{aligned} \dot{X} &= (A + BK)X + X(A + BK)' \\ &\quad + (C + DK)X(C + DK)', \end{aligned} \quad (14)$$

$$X(0) = X_0 = x_0 x_0', \quad (15)$$

$$\begin{aligned} \text{tr}(Q_1 X(T)) &= l_1, \\ \text{tr}(Q_2 X(T)) &= l_2, \\ &\dots \\ \text{tr}(Q_q X(T)) &= l_q. \end{aligned} \quad (16)$$

Remark 7. It is obvious that if Problem 1 has the optimal linear feedback control $u_*(t) = K_*(t)x(t)$, then $K_*(t)$ must be the solution of Problem 6, while the inverse does not hold.

Take the objective functional $J(X, K)$ as a functional defined on the space $C^{n \times n}[0, T] \times C^{n \times n}[0, T]$, in which $C^{n \times n}[0, T]$ is an $n \times n$ square matrix space, the element in this space is the continuous function defined on $[0, T]$:

$$\begin{aligned} H(X, K)(t) &= X(t) - X(0) \\ &\quad - \int_0^t [(A + BK)X + X(A + BK)' \\ &\quad + (C + DK)X(C + DK)'] dt, \end{aligned} \quad (17)$$

and terminal state constraints (16) defines a transformation $G(X)$ from $C^{n \times n}[0, T]$ to R^q :

$$G(x(T)) = \begin{pmatrix} \text{tr}(Q_1 X(T)) \\ \vdots \\ \text{tr}(Q_q X(T)) \end{pmatrix}. \quad (18)$$

By the virtue of (17)-(18), constraints (14)-(16) can be reformulated as

$$H(X, K)(t) = 0, \quad G(X(T)) = L, \quad \forall t \in [0, T]. \quad (19)$$

Lemma 8. Functional $J(X, K)$, $H(X, K)$, $G(X)$ are continuous Frechet differentiable functionals and have Frechet derivative

$$\delta J_X(X, K; \Delta X) = \text{tr} \int_0^T (Q + K'RK) \Delta X dt, \quad (20)$$

$$\delta J_K(X, K; \Delta K) = \text{tr} \int_0^T (\Delta K'RKX + K'R\Delta KX) dt, \quad (21)$$

$$\begin{aligned} \delta H_X(X, K; \Delta X)(t) &= \Delta X(t) - \int_0^t [(A + BK)\Delta X + \Delta X(A + BK)' \\ &\quad + (C + DK)\Delta X(C + DK)'] dt, \end{aligned} \quad (22)$$

$$\begin{aligned} \delta H_K(X, K; \Delta K)(t) &= - \int_0^t [B\Delta KX + X\Delta K'B' + (C + DK)X(D\Delta K) \\ &\quad + D\Delta KX(C + DK)'] dt, \end{aligned} \quad (23)$$

$$\delta G_X(X; \Delta X(T)) = \begin{pmatrix} \text{tr}(Q_1 \Delta X(T)) \\ \vdots \\ \text{tr}(Q_q \Delta X(T)) \end{pmatrix}. \quad (24)$$

Proof. The proof is mainly based on Definition 2. Apply Definition 2 to the functional constraints (19); the proofs for the first three results are the same to those in [8], and we only need the proof of (24) here:

$$\begin{aligned}\Delta G(X; \Delta X) &= \lim_{\alpha \rightarrow 0} \frac{G(X; X + \alpha \Delta X) - G(X)}{\alpha}, \\ G(X; X + \alpha X) - G(X) &= \begin{pmatrix} \text{tr}(Q_1 X(T) + \alpha \Delta X(T)) \\ \vdots \\ \text{tr}(Q_q X(T) + \alpha \Delta X(T)) \end{pmatrix} - \begin{pmatrix} \text{tr}(Q_1 X(T)) \\ \vdots \\ \text{tr}(Q_q X(T)) \end{pmatrix}, \\ \delta G(X, \Delta X) &= \lim_{\alpha \rightarrow 0} \frac{G(X; X + \Delta X) - G(X)}{\alpha} \\ &= \begin{pmatrix} \text{tr}(Q_1 \Delta X) \\ \vdots \\ \text{tr}(Q_q \Delta X) \end{pmatrix}. \end{aligned} \quad (25)$$

Lemma 9. Constraint (19) satisfies the regular condition; that is,

$$\delta H(X, K; \Delta X, \Delta K), \quad \delta G(X; \Delta X(T)) \quad (26)$$

are onto mapping when

$$\Delta X \times \Delta K \in C^{n \times n} \times C^{m \times n}. \quad (27)$$

Proof. The proof of the onto mapping for $\delta H(X, K; \Delta X, \Delta K)$ has been given in [8]; we only need to prove that $\delta G(X; \Delta X)$ is a onto mapping when ΔX varies. For a given $Y \in R^q$, the following equation has a solution:

$$\begin{pmatrix} \text{tr}(Q_1 \Delta X) \\ \vdots \\ \text{tr}(Q_q \Delta X) \end{pmatrix} = Y. \quad (28)$$

Because the coefficient matrix for quadratic terminal state constraints is full row rank (Assumption H_1), equation

$$\begin{pmatrix} m_{11} & \cdots & m_{1n} \\ \vdots & \vdots & \vdots \\ m_{q1} & \cdots & m_{qn} \end{pmatrix} \begin{pmatrix} \Delta X_{11} \\ \vdots \\ \Delta X_{qn} \end{pmatrix} = Y, \quad (29)$$

exists a solution, which finishes the proof. $\square$

Definition 10 (the well-posedness). The LQ optimal control problem is to minimize the cost functional $J(x_0, u)$ over $u \in U_{\text{ad}}$. Define the optimal value function as $V(x_0) = \inf_{u \in U_{\text{ad}}} J(x_0, u)$. The LQ problem is called well posed if

$$-\infty < V(x_0) < +\infty, \quad \forall x_0 \in R^n. \quad (30)$$

A well-posed problem is called attainable (with respect to x_0) if there is a $u_*(\cdot)$ control that achieves $V(x_0)$.

Theorem 11 (Lagrange multiplier theorem). If the continuously Frechet differentiable real functional f defined on Banach space has a local extremum under the constraint $H(x) = 0$ at the regular point x_0 , $H(x)$ is a mapping from space X to Banach space Z , and then there exists an element $z_0^* \in Z^*$ such that the Lagrangian functional

$$L(x) = f(x) + z_0^* H(x) \quad (31)$$

is stationary at x_0 ; that is,

$$\delta f(x_0; h) + z_0^* \delta H(x_0; h) = 0 \quad (32)$$

for each $h \in X$.

Theorem 12 (Riesz representation theorem). Let $f(x)$ be a bounded linear functional on $X = C[a, b]$, and then there is a bounded variation function v on $[a, b]$ such that, for all $x \in X$,

$$f(x) = \int_a^b x(t) dv(t), \quad (33)$$

where the norm of $f(x)$ is the total variation on $[a, b]$. Conversely, every function of bounded variation on $[a, b]$ defines a bounded linear function on X in this way.

3. Main Results

Lemma 13 (see [9]). If $\alpha(t)$ is continuous in $[t_1, t_2]$ and $\int_{t_1}^{t_2} \alpha(t) dh(t) = 0$ for every $h \in D[t_1, t_2]$ (set of all continuously differentiable functions on $[t_1, t_2]$) with $h(t_1) = h(t_2) = 0$, then $\alpha(t) = 0$ on $[t_1, t_2]$.

Lemma 14 (see [9]). If $\alpha(t)$ is continuous in $[t_1, t_2]$ and $\int_{t_1}^{t_2} \alpha(t) dh(t) = 0$ for every $h \in D[t_1, t_2]$ with $h(t_1) = h(t_2) = 0$, then $\alpha(t) = c$ in $[t_1, t_2]$, where c is a constant.

Lemma 15 (see [9]). If $\alpha(t)$ and $\beta(t)$ are continuous in $[t_1, t_2]$ and

$$\int_{t_1}^{t_2} [\alpha(t) h(t) + \beta(t) h'(t)] dt = 0 \quad (34)$$

for every $h \in D[t_1, t_2]$ with $h(t_1) = h(t_2) = 0$, then β is differentiable and $\dot{\beta}(t) = \alpha(t)$ in $[t_1, t_2]$.

We make use of $NBV^{n \times n}[0, T]$ (nonnegative bounded variation functional on $[0, T]$) to express the matrix space with the element in $[0, T]$. The space is a bounded variation right continuous function that function takes value 0 at the point at the point $t = 0$. Based on the Lagrangian theorem and the Riesz representation theorem, we obtained a necessary condition for Problem 1.

3.1. Necessary Condition

Theorem 16 (necessary condition for indefinite stochastic LQ with quadratic constraints). Suppose the set defined by the terminal state constraint is not empty and the optimal control

Problem 6 exists an optimal feedback control matrix K_* ; then there must exist a symmetric matrix $P \in \text{NBV}^{n \times n}[0, T]$ and a vector $\lambda \in R^q$ such that for all $t \in [0, T]$, P and λ satisfy the following equations:

$$-\dot{P} = (Q + K_*'RK_*) + P(A + BK_*) + (A + BK_*)'P + (C + DK_*)'P(C + DK_*), \quad (35)$$

$$P(T) = \sum_{i=1}^q \lambda_i Q_i, \quad (36)$$

$$K_*'R + PB + (C + DK_*)'PD = 0. \quad (37)$$

Proof. From Remark 7, we know that K_* is the solution of deterministic optimal control Problem 6; take X and K in Problem 6 as the variables. Suppose that (X_*, K_*) is the optimal solution for Problem 6; according to Lemmas 14 and 15, Problem 6 satisfies the conditions of Lagrange multiplier theorem, and then there exists a symmetric matrix $P \in \text{NBV}^{n \times n}[0, T]$ and $\lambda \in R^q$ such that

$$\begin{aligned} & \text{tr} \int_0^T (Q + K_*'RK_*) \Delta X dt \\ & + \text{tr} \int_0^T \left(\Delta X - \int_0^t (A + BK_*) \Delta X + \Delta X (A + BK_*) \right. \\ & \quad \left. + (C + DK_*) \Delta X (C + DK_*)' dt \right) dP \\ & + \lambda' \begin{pmatrix} \text{tr}(Q_1 X) \\ \vdots \\ \text{tr}(Q_q X) \end{pmatrix} = 0, \end{aligned} \quad (38)$$

$$\begin{aligned} & \text{tr} \int_0^T (\Delta K'RK_*X_* + K_*'R\Delta KX_*) dt \\ & - \text{tr} \int_0^T \left(\int_0^t B\Delta KX_* + X_*\Delta K'B' + (C + DK_*)X_* \right. \\ & \quad \left. \times (D\Delta K') + (D\Delta K)X_*(C + DK_*)' dt \right) dP \\ & = 0. \end{aligned} \quad (39)$$

The second parts of (38) and (39) are from Riesz representation theorem. In general, we take that $P(T) = 0$, and then (38) becomes

$$\begin{aligned} & \text{tr} \int_0^T (Q + K_*'RK_*) \Delta X dt + \text{tr} \int_0^T \Delta X dP \\ & + \text{tr} \int_0^T \left(P[(A + BK_*) \Delta X + \Delta X (A + BK_*) \right. \\ & \quad \left. + (C + DK_*) \Delta X (C + DK_*)'] \right) \\ & + \text{tr} (\lambda_1 Q_1 X + \cdots + \lambda_q Q_q X) = 0. \end{aligned} \quad (40)$$

It is obvious that there is no jump in interval $[0, T)$ for function $P(t)$, otherwise we can choose ΔX that makes $\text{tr} \int_0^T \Delta X dP$ be far more than the other parts in the equality. But $P(t)$ has jump at the point $t = T$, and the height is

$$(\lambda_1, \dots, \lambda_q) \begin{pmatrix} \text{tr}(Q_1 X(T)) \\ \vdots \\ \text{tr}(Q_q X(T)) \end{pmatrix}. \quad (41)$$

Because the previous equalities (38) and (39) hold for all continuous functions ΔX , for specified function which has continuous derivative and $\Delta X(T) = 0$, all the previous equalities also hold, and then

$$\begin{aligned} \int_0^T \Delta X dP &= P\Delta X|_0^T - \int_0^T P\Delta \dot{X} dt \\ &= P(T)\Delta X(T) - P(0)\Delta X(0) - \int_0^T P\Delta \dot{X} dt \\ &= P(T)\Delta X(T) - \int_0^T P\Delta \dot{X} dt. \end{aligned} \quad (42)$$

Because $P(T) = 0$, then

$$\int_0^T \Delta X dP = - \int_0^T P\Delta \dot{X} dt, \quad (43)$$

and we have the following from (38)

$$\begin{aligned} & \text{tr} \int_0^T (Q + K_*'RK_*) \Delta X + P(A + BK_*) \Delta X + (A + BK_*)' \\ & \quad \times P\Delta X + (C + DK_*)'P(C + DK_*) \Delta X - P\Delta \dot{X} dt = 0. \end{aligned} \quad (44)$$

According to Lemma 15, we have

$$\begin{aligned} -\dot{P} &= (Q + K_*'RK_*) + P(A + BK_*) \\ & + (A + BK_*)'P + (C + DK_*)'P(C + DK_*). \end{aligned} \quad (45)$$

We take the integral by parts of the second part of (39), and then

$$\begin{aligned} & \text{tr} \int_0^T [K_*'R(\Delta K)X_* + PB(\Delta KX_*) \\ & \quad + (C + DK_*)'PD(\Delta KX_*)] dt = 0. \end{aligned} \quad (46)$$

Based on Lemma 13, we have

$$K_*'R + PB + (C + DK_*)'PD = 0. \quad (47)$$

Change the endpoint conditions $P(T) = 0$ with $P(T) = \lambda_1 Q_1 + \cdots + \lambda_q Q_q$; that is, (36) holds. $\square$

Remark 17. The necessary condition in Theorem 16 (35)–(37) and the constraints (14)–(16) in Problem 6 have $2n$ one order differential equations, $2n$ bound conditions, q terminal state conditions, and m algebra equations, and then we can determine $X_*(t)$, $K_*(t)$, $P(t)$, and λ , respectively.

Remark 18. The result in Theorem 12 is the same as that in [8] except for the terminal conditions.

3.2. Sufficient Condition. We have pointed out that the necessary conditions (14)–(16) and (35)–(37) are not sufficient for the existence and the uniqueness of the solution in Problem 6. In order to guarantee the uniqueness of λ and $P(t)$, the conditions must be strengthened to

$$P + D'PD > 0; \quad (48)$$

that is, the matrix $R + D'PD$ must be positive.

Theorem 19 (sufficient condition for stochastic LQ problem with quadratic constraints). *If (14)–(16), (35)–(37), and (39) exist solutions $X_*(t)$, $K_*(t)$, $P(t)$, and λ , then Problem 6 is well posed and the optimal feedback control is*

$$u_*(t) = -(R + D'PD)^{-1} (B'P + D'PC) x(t); \quad (49)$$

the optimal cost value is

$$V(x_0) = \inf_{u(\cdot) \in U_{ad}} J(x_0, u(t)) = x(0)' P(0) x(0) - \lambda' L. \quad (50)$$

Proof. Suppose that $K_*(t)$, $P(t)$, and λ are the solutions that satisfy (14)–(16), (35)–(37), and (48), and from (37), we have

$$K_*(t) = -(R + D'PD)^{-1} (B'P + D'PC). \quad (51)$$

Substitute $K_*(t)$ in (35), and then

$$\begin{aligned} & \dot{P} + PA + A'P + C'PC + Q \\ & - (PB + C'PD)(R + D'PD)^{-1}(PB + C'PD) = 0, \\ & J(x_0, u(\cdot)) \\ & = E \int_0^T [x'Qx + u'Ru] dt + d(x'Px) - d(x'Px). \end{aligned} \quad (52)$$

Apply Itô's formula again, so

$$\begin{aligned} & = x'(0) P(0) x(0) - E(x'(T) P(T) x(T)) \\ & + E \int_0^T x' (\dot{P} + PA + A'P + C'PC + Q) x \\ & + 2u' (B'P + D'PC) x + u' (R + D'PD) u dt \\ & = x'(0) P(0) x(0) - \lambda' \begin{pmatrix} \text{tr}(Q_1 X(T)) \\ \vdots \\ \text{tr}(Q_q X(T)) \end{pmatrix} \\ & + E \int_0^T x' \left[\dot{P} + PA + A'P + C'PC + Q - (PB + C'PD) \right. \\ & \quad \left. \times (R + D'PD)^{-1} (PB + C'PD)' \right] x dt \\ & + E \int_0^T \left[u + (R + D'PD)^{-1} (B'P + D'PC) x \right]' \end{aligned}$$

$$\begin{aligned} & \times (R + D'PD) \left[u + (R + D'PD)^{-1} \right. \\ & \quad \left. \times (B'P + D'PC) x \right] dt \\ & = x'(0) P(0) x(0) - \lambda' \begin{pmatrix} \text{tr}(Q_1 X(T)) \\ \vdots \\ \text{tr}(Q_q X(T)) \end{pmatrix} \\ & + E \int_0^T \left[u + (R + D'PD)^{-1} (B'P + D'PC) x \right]' \\ & \quad \times (R + D'PD) \left[u + (R + D'PD)^{-1} \right. \\ & \quad \left. \times (B'P + D'PC) x \right] dt, \end{aligned} \quad (53)$$

where the last equality is from (52). It is obvious that linear feedback control (49) has the minimum cost $J(x_0, u(t))$, and the cost value is

$$x'(0) P(0) x(0) - \lambda' \begin{pmatrix} \text{tr}(Q_1 X(T)) \\ \vdots \\ \text{tr}(Q_q X(T)) \end{pmatrix}. \quad (54)$$

□

3.3. Necessary Conditions for Stochastic LQ with Mixed Terminal State Constraint. We study the following indefinite stochastic LQ control problem with mixed constraints.

Problem 20. Consider

$$\inf \left\{ J(x_0, u) := E \int_0^T x'Qx + u'Ru dt \right\} \quad (55)$$

s.t.

$$dx(t) = (A(t)x(t) + B(t)u(t))$$

$$+ (C(t)x(t) + D(t)u(t)) d\omega(t),$$

$$x(0) = x_0,$$

$$m_{1,1}x_{1,1}(T) + m_{1,2}x_{1,2}(T) + \cdots + m_{1,n}x_{1,n}(T) = \xi_1,$$

$$m_{2,1}x_{2,1}(T) + m_{2,2}x_{2,2}(T) + \cdots + m_{2,n}x_{2,n}(T) = \xi_2,$$

$$\dots$$

$$m_{l,1}x_{l,1}(T) + m_{l,2}x_{l,2}(T) + \cdots + m_{l,n}x_{l,n}(T) = \xi_l,$$

$$m_{l+1,1}x_{l+1,1}^2(T) + m_{l+1,2}x_{l+1,2}^2(T) + \cdots + m_{l+1,n}x_{l+1,n}^2(T)$$

$$= \xi_{l+1},$$

$$m_{l+2,1}x_{l+2,1}^2(T) + m_{l+2,2}x_{l+2,2}^2(T) + \cdots + m_{l+2,n}x_{l+2,n}^2(T)$$

$$= \xi_{l+2},$$

...

$$m_{l+q,1}x_{l+q,1}^2(T) + m_{l+q,2}x_{l+q,2}^2(T) + \cdots + m_{l+q,n}x_{l+q,n}^2(T) = \xi_{l+q}. \quad (56)$$

Using the same method as the above, the stochastic LQ control problem with linear and quadratic terminal constraints can be transformed into the following Problem 21.

Problem 21. Consider

$$\inf J(X, K) = \text{tr} \int_0^T [QX(t) + K'(t)RK(t)X(t)] dt \quad (57)$$

s.t.

$$\begin{aligned} \dot{X} &= (A + BK)X + X(A + BK)' \\ &+ (C + DK)X(C + DK)', \\ X(0) &= X_0 = x_0x_0', \\ M_l X(T) M_l' &= N, \\ \text{tr}(Q_1 X(T)) &= l_1, \\ \text{tr}(Q_2 X(T)) &= l_2, \\ &\dots \\ \text{tr}(Q_q X(T)) &= l_q. \end{aligned} \quad (58)$$

Theorem 22 (necessary and sufficient conditions for stochastic LQ problem with mixed constraint). *Suppose that the terminal constraint set defined by the linear and quadratic state constraints is not empty and the optimal control Problem 6 exists the optimal feedback control matrix K_* . Then there must exist a symmetric matrix $P \in \text{NBV}^{n \times n}[0, T]$ and a vector $\lambda \in R^q$, $\mu \in R^{l \times 1}$, for all $t \in [0, T]$, satisfying the following equalities:*

$$\begin{aligned} -\dot{P} &= (Q + K_*'RK_*) + P(A + BK_*) + (A + BK_*)'P \\ &+ (C + DK_*)'P(C + DK_*), \\ P(T) &= \sum_{i=1}^q \lambda_i Q_i + M_l' \mu M_l, \\ K_*'R + PB + (C + DK_*)'PD &= 0. \end{aligned} \quad (59)$$

If (14)–(16), (35)–(37), and (39) exist solutions $X_*(t)$, $K_*(t)$, $P(t)$, and λ , then Problem 6 is well posed and the optimal feedback control is

$$u_*(t) = -(R + D'PD)^{-1} (B'P + D'PC)x(t). \quad (60)$$

The optimal value is

$$\begin{aligned} V(x_0) &= \inf_{u(\cdot) \in U_{ad}} J(x_0, u(t)) \\ &= x_0' P(0) x(0) - \lambda' L_q - \text{tr}(\mu N). \end{aligned} \quad (61)$$

The proof of the theorem is the same as that of Theorem 16 except for the terminal condition.

4. Numerical Examples

Let $A = -1$, $B = 1$, $C = -2$, $D = 0$, $M_q = 1$, $L = e^2$, $X_0 = 2$, $Q = 0$, $R = 1$, and $T = 1$ in Problem 6, according to (35)–(37) in Theorem 16 and the constraint (14)–(16) in Problem 1, and then

$$\begin{aligned} -\dot{P} &= K_*^2 + 2P(K_* - 1) + 4P, \\ P(1) &= \lambda, \\ K_* + P &= 0, \\ X_* &= 2(K_* - 1)X_* + 4X_*, \\ X(0) &= 2, \\ X_*^2(1) &= e^2. \end{aligned} \quad (62)$$

Solve the system equations, and then

$$\begin{aligned} X_*(t) &= \frac{e}{e-1} + \frac{e-2}{e-1}e^{2t}, \quad K_*(t) = \frac{2}{(2/e-1)e^{2t}-1}, \\ P(t) &= \frac{2}{1-(2/e-1)e^{2t}}, \quad \lambda = \frac{2}{e^2-2e+1}. \end{aligned} \quad (63)$$

The optimal control for Problem 6 is $u_*(t) = 2e(e-2)e^{2t}/((2/e-1)e^{2t}-1)$, and the optimal index cost value is

$$J(x_0, u_*(t)) = \frac{2e^2 - 4e}{(e-1)^2}. \quad (64)$$

5. Conclusion

This paper studied a class of indefinite stochastic LQ control problems with quadratic terminal state constraints and mixed terminal state constraints. By means of the Lagrange multiplier theorem and Riesz representation theorem, this paper presented a necessary condition for indefinite stochastic LQ control problems with quadratic terminal state constraints and mixed terminal state constraints. The result shows that the necessary condition for quadratic terminal constraints is the same as for the linear terminal state constraints that is presented in [8] except for the terminal condition. This coincides with the reality. A sufficient condition also was presented for the existence and uniqueness of the optimal linear feedback control. Numerical example verified the main theorem in this paper.
