The generalized Nash equilibrium problem (GNEP) is an extension of the standard Nash equilibrium problem (NEP), in which each player’s strategy set may depend on the rival player’s strategies. In this paper, we present two descent type methods. The algorithms are based on a reformulation of the generalized Nash equilibrium using Nikaido-Isoda function as unconstrained optimization. We prove that our algorithms are globally convergent and the convergence analysis is not based on conditions guaranteeing that every stationary point of the optimization problem is a solution of the GNEP.

1. Introduction

The generalized Nash equilibrium problem (GNEP for short) is an extension of the standard Nash equilibrium problem (NEP for short), in which the strategy set of each player depends on the strategies of all the other players as well as on his own strategy. The GNEP has recently attracted much attention due to its applications in various fields like mathematics, computer science, economics, and engineering [1–11]. For more details, we refer the reader to a recent survey paper by Facchinei and Kanzow [3] and the references therein.

Let us first recall the definition of the GNEP. There are \( N \) players labelled by an integer \( v = 1, \ldots, N \). Each player \( v \) controls the variables \( x^v \in \mathbb{R}^{n_v} \). Let \( x = (x^1 \cdots x^N)^T \) be the vector formed by all these decision variables, where \( n := n_1 + n_2 + \cdots + n_N \). To emphasize the \( v \)th player variable within the vector \( x \), we sometimes write \( x = (x^v, x^{-v})^T \in \mathbb{R}^n \), where \( x^{-v} \) denotes all the other player’s variables. In the games, each player controls the variables \( x^v \) and tries to minimize a cost function \( \theta_v(x^v, x^{-v}) \) subject to the constraint \( (x^v, x^{-v})^T \in X \) with \( x^{-v} \) given as exogenous, where \( X \) is a common strategy set. A vector \( x^* := (x^{v_1}, \ldots, x^{v_N})^T \) is called a solution of the GNEP or a generalized Nash equilibrium, if for each player \( v = 1, \ldots, N \), \( x^v \) solves the following optimization problem with \( x^{v,-v} \) being fixed:

\[
\begin{align*}
\min_{x^v} & \quad \theta_v(x^v, x^{v,-v}), \\
\text{s.t.} & \quad (x^v, x^{v,-v}) \in X.
\end{align*}
\]

If \( X \) is defined as the Cartesian product of certain sets \( X_v \in \mathbb{R}^{n_v} \), that is, \( X = X_1 \times X_2 \times \cdots \times X_N \), then the GNEP reduces to the standard Nash equilibrium problem.

Throughout this paper, we can make the following assumption.

Assumption 1. (a) The set \( X \) is nonempty, closed, and convex. (b) The utility function \( \theta_v \) is continuously differentiable and, as a function of \( x^v \) alone, convex.

A basic tool for both the theoretical and the numerical solution of (generalized) Nash equilibrium problems is the Nikaido-Isoda function defined as

\[
\Psi(x, y) = \sum_{i=1}^{N} \left[ \theta_v(x^v, x^{-v}) - \theta_v(y^v, x^{-v}) \right].
\]

Sometimes also the name Ky-Fan function can be found in the literature, see [12, 13]. In the following, we state a definition which we have taken from [9].

Definition 1. \( x^* \) is a normalized Nash equilibrium of the GNEP if \( \max_x \Psi(x^*, y) = 0 \) holds, where \( \Psi(x, y) \) denotes the Nikaido-Isoda function defined as (2).

In order to overcome the nondifferentiable property of the mapping \( \Psi(x, y) \), von Heusinger and Kanzow [8] used a simple regularization of the Nikaido-Isoda function. For
a parameter $\alpha > 0$, the following regularized Nikaido-Isoda function was considered:

$$
\Psi_{\alpha} (x, y) = \sum_{v=1}^{N} \left[ \theta_{v} (x^{v}, x^{-v}) - \theta_{v} (y^{v}, x^{-v}) \right] - \alpha \frac{\|x - y\|^2}{2}.
$$

(3)

Since under the given Assumption 1, $\Psi_{\alpha}(x, y)$ is strongly concave in $x$, the maximization problem

$$
\max_{y} \Psi_{\alpha} (x, y),
$$

s.t. $y \in X$

has a unique solution for each $x$, denoted by $y_{\alpha}(x)$.

The corresponding value function is then defined by

$$
V_{\alpha} (x) = \max_{y} \Psi_{\alpha} (x, y) = \Psi_{\alpha} (x, y_{\alpha} (x)).
$$

(5)

Let $\beta > \alpha > 0$ be a given parameter. The corresponding value function is then defined by

$$
V_{\beta} (x) = \max_{y} \Psi_{\beta} (x, y) = \Psi_{\beta} (x, y_{\beta} (x)).
$$

(6)

Define

$$
V_{\alpha\beta} (x) = V_{\alpha} (x) - V_{\beta} (x).
$$

(7)

In [8], the following important properties of the function $V_{\alpha\beta}(x)$ have been proved.

**Theorem 2.** The following statements hold:

(a) $V_{\alpha\beta}(x) \geq 0$ for any $x \in \mathbb{R}^{n}$;

(b) $x^{*}$ is a normalized Nash equilibrium of the GNEP if and only if $V_{\alpha\beta}(x^{*}) = 0$;

(c) $V_{\alpha\beta}(x)$ is continuously differentiable on $\mathbb{R}^{n}$ and that

$$
\nabla V_{\alpha\beta} (x) = \nabla V_{\alpha} (x) - \nabla V_{\beta} (x)
$$

$$
= \sum_{v=1}^{N} \left[ \nabla \theta_{v} (y_{\beta}(x)^{v}, x^{-v}) - \nabla \theta_{v} (y_{\alpha}(x)^{v}, x^{-v}) \right] + \left( \begin{array}{c}
\nabla_{x} \theta_{1} (y_{\alpha}(x)^{1}, x^{-1}) - \nabla_{x} \theta_{1} (y_{\beta}(x)^{1}, x^{-1}) \\
\vdots \\
\nabla_{x} \theta_{N} (y_{\alpha}(x)^{N}, x^{-N}) - \nabla_{x} \theta_{N} (y_{\beta}(x)^{N}, x^{-N}) \\
- \alpha (x - y_{\alpha}(x)) + \beta (x - y_{\beta}(x))
\end{array} \right).
$$

(8)

From Theorem 2, we know that the normalized Nash equilibrium of the GNEP is precisely the global minima of the smooth unconstrained optimization problem (see [5]) as

$$
\min_{x \in \mathbb{R}^{n}} V_{\alpha\beta} (x)
$$

with zero optimal value.

In this paper, we develop two new descent methods for finding a normalized Nash equilibrium of the GNEP by solving the optimization problem (9). The key to our methods is a strategy for adjusting $\alpha$ and $\beta$ when a stationary point of $V_{\alpha\beta}(x)$ is not a solution of the GNEP. We will show that our algorithms are globally convergent to a normalized Nash equilibrium under appropriate assumption on the cost function, which is not stronger than the one considered in [8].

The organization of the paper is as follows. In Section 2, we state the main assumption underlying our algorithms and present some examples of the GNEPs satisfying it. In Section 3, we derive some useful properties of the function $V_{\alpha\beta}(x)$. In Section 4, we formally state our algorithms and prove that they are both globally convergent to a normalized Nash equilibrium.

**2. Main Assumption**

In order to construct algorithms and guarantee the convergence of them, we give the following assumption.

**Assumption 2.** For any $\beta > \alpha > 0$ and $x \in \mathbb{R}^{n}$, if $y_{\alpha}(x) \neq y_{\beta}(x)$, we have

$$
\sum_{v=1}^{N} \left( \nabla \theta_{v} (y_{\beta}(x)^{v}, x^{-v}) - \nabla \theta_{v} (y_{\alpha}(x)^{v}, x^{-v}) \right)^{T} (y_{\beta}(x)^{v} - y_{\alpha}(x)^{v})^{v} + (y_{\beta}(x)^{v} - y_{\alpha}(x)^{v})^{v}.
$$

(10)

We next consider three examples which satisfy Assumption 2.

**Example 3.** Let us consider the case in which all the cost functions are separable, that is,

$$
\theta_{v} (x) = f_{v} (x^{v}) + g_{v} (x^{-v}),
$$

(11)

where $f_{v} : \mathbb{R}^{n_{v}} \rightarrow \mathbb{R}$ is convex and $g_{v} : \mathbb{R}^{n-n_{v}} \rightarrow \mathbb{R}$. A simple calculation shows that, for any $y \in \mathbb{R}^{n}$, we have

$$
\sum_{v=1}^{N} \left( \nabla_{x} \theta_{v} (y_{\beta}(x)^{v}, x^{-v}) - \nabla_{x} \theta_{v} (y_{\alpha}(x)^{v}, x^{-v}) \right)^{T} (y_{\beta}(x)^{v} - y_{\alpha}(x)^{v})^{v} + (y_{\beta}(x)^{v} - y_{\alpha}(x)^{v})^{v}.
$$

(12)

Hence Assumption 2 holds.
Example 4. Consider the case where the cost function \( \theta_v(x) \) is quadratic, that is,
\[
\theta_v(x) = \frac{1}{2}(x^v)^T A_{vv} x^v + \sum_{\mu=1, \mu \neq v}^{N} (x^\mu)^T A_{v\mu} x^\mu \tag{13}
\]
for \( v = 1, \ldots, N \). We have
\[
\sum_{v=1}^{N} \left( \nabla_x \theta_v(y^\alpha(x)^v, x^{-v}) - \nabla_x \theta_v(y^\beta(x)^v, x^{-v}) \right)^T \cdot (y^\beta(x)^v - y^\alpha(x)^v)
\]
\[
= \sum_{v=1}^{N} \langle y^\beta(x)^v - y^\alpha(x)^v, A_{vv} (y^\beta(x)^v - y^\alpha(x)^v) \rangle,
\]
\[
\sum_{v=1}^{N} \left( \nabla \theta_v(y^\beta(x)^v, x^{-v}) - \nabla \theta_v(y^\alpha(x)^v, x^{-v}) \right)^T \cdot (y^\beta(x)^v - y^\alpha(x)^v)
\]
\[
\geq 0.
\]
Therefore, if the matrix
\[
\begin{pmatrix}
0 & A_{12} & \cdots & A_{1N} \\
A_{21} & 0 & \cdots & A_{2N} \\
\vdots & \vdots & \ddots & \vdots \\
A_{N1} & A_{N2} & \cdots & 0
\end{pmatrix}
\]
(15)
is positive semidefinite, Assumption 2 is satisfied.

In the following example, we show the relationship between our assumption and the one considered in [8] as follows.

For any \( \beta > \alpha > 0 \), a given \( x \in \mathbb{R}^n \) with \( y^\alpha(x) \neq y^\beta(x) \), the inequality
\[
\sum_{v=1}^{N} \left( \nabla \theta_v(y^\beta(x)^v, x^{-v}) - \nabla \theta_v(y^\alpha(x)^v, x^{-v}) \right)^T \cdot (y^\beta(x)^v - y^\alpha(x)^v) > 0
\]
holds.

Example 5. Consider the GNEP with \( N = 2 \) as
\[
X = \{ x \in \mathbb{R}^n : x^1 \geq 1, x^2 \geq 1, x^1 + x^2 \leq 10 \}
\]
and the cost function \( \theta_1(x) = x^1 x^2 \) and \( \theta_2(x) = -x^1 x^2 \). The point \( x^* = (1,9)^T \) is the unique normalized Nash equilibrium. For any \( y \in \mathbb{R}^2 \), we have
\[
\sum_{v=1}^{N} \left( \nabla \theta_v(y^\beta(x)^v, x^{-v}) - \nabla \theta_v(y^\alpha(x)^v, x^{-v}) \right)^T \cdot (y^\beta(x)^v - y^\alpha(x)^v) = 0,
\]
\[
\sum_{v=1}^{N} \left( \nabla \theta_v(y^\beta(x)^v, x^{-v}) - \nabla \theta_v(y^\alpha(x)^v, x^{-v}) \right)^T \cdot (y^\beta(x)^v - y^\alpha(x)^v) = 0.
\]
Therefore Assumption 2 holds, but (16) does not hold for any \( \beta > \alpha > 0 \).

3. Properties of \( V_{\alpha \beta}(x) \)

Lemma 6. For any \( \beta > \alpha > 0 \) and \( x \in \mathbb{R}^n \), we have
\[
V_{\alpha \beta}(x) \geq \frac{\beta - \alpha}{2} \| x - y^\beta(x) \|^2 + \frac{\alpha}{2} \| y^\alpha(x) - y^\beta(x) \|^2,
\]
(19)
\[
V_{\alpha \beta}(x) \leq \frac{\beta - \alpha}{2} \| x - y^\alpha(x) \|^2 - \frac{\alpha}{2} \| y^\alpha(x) - y^\beta(x) \|^2.
\]
(20)

Proof. Since \( y^\alpha(x) \) satisfies the optimality condition, then
\[
\sum_{v=1}^{N} \left( \nabla \theta_v(y^\beta(x)^v, x^{-v}) - \nabla \theta_v(y^\alpha(x)^v, x^{-v}) \right)^T \cdot (y^\beta(x)^v - y^\alpha(x)^v) \geq 0.
\]
(21)
In a similar way, it follows that \( y^\beta(x) \) satisfies
\[
\sum_{v=1}^{N} \left( \nabla \theta_v(y^\beta(x)^v, x^{-v}) - \nabla \theta_v(y^\beta(x)^v, x^{-v}) \right)^T \cdot (y^\beta(x)^v - y^\alpha(x)^v) \geq 0.
\]
(22)
Since \( \theta_v(x) \) as a function of \( x^v \) alone is convex, we have
\[
\sum_{v=1}^{N} \left[ \theta_v(y^\beta(x)^v, x^{-v}) - \theta_v(y^\alpha(x)^v, x^{-v}) \right] - \alpha (x - y^\alpha(x))^T (y^\beta(x) - y^\alpha(x)) \geq 0,
\]
\[
\sum_{v=1}^{N} \left[ \theta_v(y^\alpha(x)^v, x^{-v}) - \theta_v(y^\beta(x)^v, x^{-v}) \right] - \beta (x - y^\beta(x))^T (y^\alpha(x) - y^\beta(x)) \geq 0
\]
(23)
(24)
respectively. Thus, using the definition of $V_{\alpha\beta}(x)$ and (23), we have

$$V_{\alpha\beta}(x) = \sum_{v=1}^{N} \left[ \theta_v(y_{\alpha}(x)^v, x^{-v}) - \theta_v(y_{\beta}(x)^v, x^{-v}) \right] + \frac{\beta}{2} \| x - y_{\beta}(x) \|^2 - \frac{\alpha}{2} \| x - y_{\alpha}(x) \|^2 \geq \alpha (x - y_{\alpha}(x))^T (y_{\beta}(x) - y_{\alpha}(x))$$

$$+ \frac{\beta}{2} \| x - y_{\beta}(x) \|^2 - \frac{\alpha}{2} \| x - y_{\alpha}(x) \|^2 \geq \alpha (x - y_{\alpha}(x))^T (y_{\beta}(x) - y_{\alpha}(x))$$

$$+ \frac{\beta}{2} \| x - y_{\beta}(x) \|^2 - \frac{\alpha}{2} \| x - y_{\alpha}(x) \|^2 = \alpha (x - y_{\alpha}(x))^T (y_{\beta}(x) - y_{\alpha}(x)) + \frac{\beta}{2} \| x - y_{\beta}(x) \|^2$$

$$- \frac{\alpha}{2} \| x - y_{\beta}(x) + y_{\beta}(x) - y_{\alpha}(x) \|^2 = \frac{\beta - \alpha}{2} \| x - y_{\beta}(x) \|^2 + \frac{\alpha}{2} \| y_{\alpha}(x) - y_{\beta}(x) \|^2. \quad (25)$$

Similarly, using the definition of $V_{\alpha\beta}(x)$ and (24), we have

$$V_{\alpha\beta}(x) \leq \frac{\beta - \alpha}{2} \| x - y_{\alpha}(x) \|^2 - \frac{\beta}{2} \| y_{\alpha}(x) - y_{\beta}(x) \|^2. \quad (26)$$

The proof is complete. \qed

Lemma 7. Assume $X$ is bounded. For any $\beta > \alpha > 0$ and $x \in \mathbb{R}^n$, we have

$$\limsup_{\beta' \to \alpha' \to 0} \frac{V_{\alpha'\beta'}(x)}{\beta' - \alpha'} \leq \frac{V_{\alpha\beta}(x)}{\beta - \alpha}. \quad (27)$$

Proof. We have from (19) that

$$2V_{\alpha\beta}(x) \geq \| x - y_{\beta}(x) \|^2 + \frac{\alpha}{\beta - \alpha} \| y_{\alpha}(x) - y_{\beta}(x) \|^2 \geq \| x - y_{\beta}(x) \|^2. \quad (28)$$

By the definition of $V_{\alpha\beta}(x)$, we have

$$2V_{\alpha'\beta'} \geq \frac{\beta' - \alpha'}{\beta' - \alpha} = \frac{2}{\beta' - \alpha'} \sum_{v=1}^{N} \left[ \theta_v(y_{\beta'}(x)^v, x^{-v}) - \theta_v(y_{\alpha'}(x)^v, x^{-v}) \right]$$

$$- \alpha' \| x - y_{\alpha'}(x) \|^2 + \beta' \| x - y_{\beta'}(x) \|^2. \quad (29)$$

Since $y_{\alpha}(x) \in X, y_{\beta}(x) \in X$ and $X$ is bounded, we get that

$$\limsup_{\beta' \to \alpha' \to 0} \frac{V_{\alpha'\beta'}(x)}{\beta' - \alpha'} \leq \frac{1}{2} \| x - y_{\beta}(x) \|^2 \leq \frac{V_{\alpha\beta}(x)}{\beta - \alpha}. \quad (30)$$

This completes the proof. \qed

Equation (8) and Assumption 2 yield

$$V_{\alpha\beta}(x)^T (y_{\beta}(x) - y_{\alpha}(x))$$

$$= \sum_{v=1}^{N} \left[ \nabla \theta_v(y_{\beta}(x)^v, x^{-v}) - \nabla \theta_v(y_{\alpha}(x)^v, x^{-v}) \right]^T$$

$$\cdot (y_{\beta}(x) - y_{\alpha}(x))$$

$$+ \left( \nabla_2 \theta_1(y_{\beta}(x)^1, x^{-1}) - \nabla_2 \theta_1(y_{\alpha}(x)^1, x^{-1}) \right)^T$$

$$\cdot \left( \nabla_2 \theta_2(y_{\beta}(x)^2, x^{-2}) - \nabla_2 \theta_2(y_{\alpha}(x)^2, x^{-2}) \right)$$

$$\cdot (y_{\beta}(x) - y_{\alpha}(x))$$

$$\leq - \left[ \alpha (x - y_{\alpha}(x)) - \beta (x - y_{\beta}(x)) \right]^T$$

$$\cdot (y_{\beta}(x) - y_{\alpha}(x)) \geq - \left[ \alpha (x - y_{\alpha}(x)) - \beta (x - y_{\beta}(x)) \right]^T$$

$$\cdot (y_{\beta}(x) - y_{\alpha}(x)) =: e_{\alpha\beta}(x) \geq 0, \quad (31)$$

where nonnegativity of $e_{\alpha\beta}(x)$ follows from the inequalities (23) and (24). In particular, either $e_{\alpha\beta}(x)$ is above a tolerance $\epsilon > 0$, in which case $y_{\alpha}(x) - y_{\beta}(x)$ is a direction of sufficient descent for $V_{\alpha\beta}(x)$ at $x$ or else, as we show in the lemma below, and $x$ is an approximate solution of the GNEP with accuracy depending on $\epsilon, \alpha, \beta$. This result will lead to our methods.

Lemma 8. For any $\beta > \alpha > 0$ and $x \in \mathbb{R}^n$, we have

$$\| x - y_{\beta}(x) \| \leq \frac{2V_{\alpha\beta}(x)}{\beta - \alpha}, \quad (32)$$

$$y_{\alpha}(x) \leq V_{\alpha}(x) \leq y_{\beta}(x) + e_{\alpha\beta}(x) + \frac{\alpha}{\beta - \alpha} \| y_{\alpha}(x) - y_{\beta}(x) \|^2, \quad (33)$$

where $y_{\alpha}(x) = \sum_{v=1}^{N} \theta_v(y_{\beta}(x)^v, x^{-v}) - \theta_v(y_{\alpha}(x)^v, x^{-v}) - (\alpha/2)\| x - y_{\beta}(x) \|^2$.

Proof. Inequality (32) follows immediately from (19) in Lemma 6.

The definition of $V_{\alpha}(x)$ implies that

$$V_{\alpha}(x) \geq \sum_{v=1}^{N} \left[ \theta_v(y_{\beta}(x)^v, x^{-v}) - \theta_v(y_{\alpha}(x)^v, x^{-v}) \right]$$

$$- \frac{\alpha}{2} \| x - y_{\beta}(x) \|^2, \quad (34)$$

which proves the first inequality in (33).

Since $e_{\alpha\beta}(x)$ is the sum of the nonnegative quantity $(\sum_{v=1}^{N} [\theta_v(y_{\beta}(x)^v, x^{-v}) - \theta_v(y_{\alpha}(x)^v, x^{-v})]) - \alpha (x - y_{\alpha}(x))^T (y_{\beta}(x) - y_{\alpha}(x)))$ with another nonnegative quantity (see (23) and (24)), we have

$$e_{\alpha}(x) \geq \sum_{v=1}^{N} \left[ \theta_v(y_{\beta}(x)^v, x^{-v}) - \theta_v(y_{\alpha}(x)^v, x^{-v}) \right]$$

$$- \alpha (x - y_{\alpha}(x))^T (y_{\beta}(x) - y_{\alpha}(x)). \quad (35)$$
Thus,
\[
V_α(x) = Y_{αβ}(x) + e_{αβ}(x) + \frac{α}{2}||y_α(x) - y_β(x)||^2,
\]
which is the second inequality in (33). This completes the proof.

4. Two Methods for Solving the GNEP

In this section, we introduce two methods for solving the GNEP, motivated by the D-gap function scheme for solving monotone variational inequalities [14, 15]. We first formally describe our methods below and then analyze their convergence using Lemma 8.

Algorithm 9. Choose an arbitrary initial point \( x^0 \in R^n \), and any \( β_0 > α_0 > 0 \). Choose any sequences of numbers \( ε^k \rightarrow 0, η_k ≥ 0, λ_k ∈ [0,1], k = 1,2, \ldots \), such that
\[
\lim_{k→∞} ε^k = \lim_{k→∞} \frac{η_k}{1 - λ_k} = 0, \sum_{k=1}^{∞} (1 - λ_k) = ∞.
\]

For \( k = 1,2, \ldots \), we iterate the following.

Iteration k. Choose any \( 0 < α_k \leq (1/2)α_{k-1} \). Choose any \( β_k ≥ 2β_{k-1} \) and \( x^k \in R^n \) satisfying
\[
\frac{V_{α_0β_k}(x^k)}{β_k - α_k} \leq η_k + λ_k \frac{V_{α_0β_{k-1}}(x^{k-1})}{β_{k-1} - α_{k-1}}.
\]

Apply a descent method to the unconstrained minimization of the function \( V_{α_0β_k} \), with \( x^k \) as the starting point and using \( y_{α_0} - y_β \) as a safeguard descent direction at \( x \), until the method generates an \( x \in R^n \) satisfying \( e_{α_0β_k}(x) ≤ ε^k \). The resulting \( x \) is denoted by \( x^k \).

Theorem 10. Assume X is bounded. Let \( \{x^k, α_k, β_k, ε_k, η_k, λ_k\}_{k=1,2, \ldots} \) be generated by Algorithm 9. Then \( \{x^k\} \) is bounded; \( β_k → ∞; α_k → 0; \) and every cluster point of \( \{x^k\} \) is a normalized Nash equilibrium of the GNEP.

Proof. Denote \( a^k = V_{α_0β_k}(x^k)/(β_k - α_k) \). By (38), we have \( a^k ≤ η_k + λ_k a^{k-1} \) for \( k = 1,2, \ldots \) and it follows from (37) that \( a^k → 0 \) ([16], Lemma 3). For each \( k ∈ \{1,2, \ldots \} \), we have from Lemma 8 that (32) and (33) hold with \( α = α_k, β = β_k, x = x^k \). This together with \( e_{α_0β_k}(x^k) ≤ ε^k \) and \( ||y_α(x^k) - y_β(x^k)|| ≤ δ(X) \) yields
\[
||x^k - y_β(x^k)|| ≤ √2a^k,
\]
where \( y^k = \sum_{i=1}^{N} [θ_i(x^k, x^k,v) - θ_i(y_β(x^k), x^k,v)] - (α/2)||x^k - y_β(x^k)||^2 \) and \( δ(X) = \text{max}_{x,y \in X} ||x - y|| \).

Since \( a^k → 0 \), the first inequality in (39) implies \( \{x^k\} \) is bounded. Moreover, this also implies \( r^k → 0 \).

Since \( α_k → 0 \), the last two inequalities in (39) yield \( V_{α_k}(x^k) → 0 \). Since for each \( y \in X \), we have \( V_{α_k}(x^k) ≥ Ψ(x,y) - (α_k/2)||x^k - y||^2 \), and this yields \( 0 ≥ Ψ(x^k, y) \) for each cluster point \( x^k \) of \( \{x^k\} \). Thus, each cluster point \( x^k \) is a normalized Nash equilibrium of the GNEP. This completes the proof.

Algorithm II. Choose any \( x^0 \in R^n \), any \( β_0 > α_0 \), and two sequences of nonnegative numbers \( ρ_k, η_k, k = 1,2, \ldots \) such that
\[
η_k + ρ_k > 0 \quad ∀k, \sum_{k=1}^{∞} ρ_k < ∞, \sum_{k=1}^{∞} η_k < ∞.
\]

Choose any continuous function \( φ : R^n → R \), with \( φ(t) = 0 ↔ t = 0 \). For \( k = 1,2, \ldots \), we iterate the following.

Iteration k. Choose any \( 0 < α_k ≤ (1/2)α_{k-1} \) and then choose \( β_k ≥ 2β_{k-1} \) satisfying
\[
\frac{V_{α_0β_k}(x^{k-1})}{β_k - α_k} ≤ (1 + ρ_k) \frac{V_{α_0β_{k-1}}(x^{k-1})}{β_{k-1} - α_{k-1}} + η_k.
\]

Apply a descent method to the unconstrained minimization of the function \( V_{α_0β_k}(x^k) \) with \( x^{k-1} \) as the starting point. We assume the descent method has the property that the amount of descent achieved at \( x \) per step is bounded away from zero whenever \( x \) is bounded and \( ||V_{α_0β_k}(x)|| \) is bounded away from zero. Then, either the method in a finite number of steps generates an \( x \) satisfying
\[
||V_{α_0β_k}(x)|| ≤ φ \left( \frac{V_{α_0β_k}(x)}{β_k - α_k} \right),
\]
which we denote by \( x^k \), or else \( V_{α_0β_k}(x) \) must decrease towards zero, in which case any cluster point of \( x \) solves the GNEP.

Theorem 12. Assume X is bounded. Let \( \{x^k, α_k, β_k, ρ_k, η_k\}_{k=1,2, \ldots} \) be generated by Algorithm II.

(a) Suppose \( x^k \) is obtained for all \( k \). Then, \( \{x^k\} \) is bounded; \( β_k → ∞; α_k → 0; \) and every cluster point of \( \{x^k\} \) is a normalized Nash equilibrium of the GNEP.

(b) Suppose \( x^k \) is not obtained for some \( k \). Then, the descent method generates a bounded sequence of \( x \) with \( V_{α_0β_k}(x) → 0 \) so every cluster point of \( x \) solves the GNEP.

Proof. (a) Since we use a descent method at iteration \( k \) to obtain \( x^{k-1} \), then \( V_{α_0β_k}(x^k) ≤ V_{α_0β_{k-1}}(x^{k-1}) \), so (41) yields
\[
\frac{V_{α_0β_k}(x^k)}{β_k - α_k} ≤ (1 + ρ_k) \frac{V_{α_0β_{k-1}}(x^{k-1})}{β_{k-1} - α_{k-1}} + η_k.
\]

Denote \( a^k = V_{α_0β_k}(x^k)/(β_k - α_k) \). This can then be written as \( a^k ≤ (1 + ρ_k)a^{k-1} + η_k \) for \( k = 1,2, \ldots \). Using \( a^k ≥ 0 \) and (41), it follows that the sequence \( \{a^k\} \) converges to some \( Π ≥ 0 \) ([16], Lemma 2). Since (32) implies
\[
||x^k - y_β(x^k)|| ≤ √2a^k, \quad ∀k
\]
the sequence \( \{x^k\} \) is bounded.
We claim that $\overline{a} = 0$. Suppose the contrary. Then for all $k$ sufficiently large, it holds that $a_k \geq \overline{a}/2$. Then,
\[
\frac{\overline{a}}{2} \leq \sum_{i=1}^{N} \left[ \theta_{\alpha_k} (y_{\beta_k}^\mu (x_k), x_k^{\mu,v}) - \theta_{\alpha_k} (y_{\beta_k}^{\alpha_k} (x_k), x_k^{\alpha_k,v}) \right] + \frac{(\alpha_k/2) \left\| x_k - y_{\alpha_k} (x_k) \right\|^2}{\beta_k - \alpha_k} \tag{45}
\]

Since, by the construction of the algorithm, $\beta_k \to \infty$ and $\alpha_k \to 0$, and $\{x_k\}$ is bounded (as are $y_{\alpha_k} (x_k)$ and $y_{\beta_k} (x_k)$), we get
\[
0 < \frac{\overline{a}}{2} \leq \liminf_{k \to \infty} \left\| x_k - y_{\beta_k} (x_k) \right\|^2. \tag{46}
\]

Then $\lim_{k \to \infty} \left\| x_k - y_{\beta_k} (x_k) \right\| = \infty$, so
\[
\lim_{k \to \infty} \left\| \nabla V_{\alpha_k \beta_k} (x_k) \right\| = \infty. \tag{47}
\]

This, together with $\left\| y_{\alpha_k} (x_k) - y_{\beta_k} (x_k) \right\| \leq \text{diam}(X)$, yields
\[
y_k \leq V_{\alpha_k} (x) \leq y_k + \epsilon_k + \frac{\alpha_k}{2} \text{diam}(X)^2, \tag{49}
\]
\[
\text{where } y_k = \sum_{i=1}^{N} \left[ \theta_{\alpha_k} (x_k^{\mu,v}, x_k^{\mu,v}) - \theta_{\alpha_k} (y_{\beta_k} (x_k^{\mu,v}), x_k^{\mu,v}) \right] - \frac{(\alpha_k/2) \left\| x_k - y_{\beta_k} (x_k) \right\|^2 \text{diam}(X)}{\beta_k - \alpha_k} \text{ and diam}(X) = \max_{x,y \in X} \|x-y\|. \quad \text{Since } a_k \to 0, (44) \text{ implies } \{x_k\} \text{ is bounded. Moreover, (44) implies } y_k \to 0. \quad \text{Also, we have } \| \nabla V_{\alpha_k \beta_k} (x_k) \| \leq \phi(a_k) \to 0, \text{ so } \epsilon_k \to 0.
\]

From the facts that $\alpha_k \to 0$, (49), $y_k \to 0$ and $\epsilon_k \to 0$, we get $V_{\alpha_k} (x_k) \to 0$. Since for each $y \in X$, we have from the definition of $V_{\alpha_k} (x)$ that
\[
V_{\alpha_k} (x_k) \geq \Psi (x, y) - \frac{\alpha_k}{2} \left\| x_k - y \right\|^2, \tag{50}
\]
which yields $0 \geq \Psi (x^{\infty}, y)$ for each cluster point $x^{\infty}$ of $\{x_k\}$. Thus, each cluster point $x^{\infty}$ is a normalized Nash equilibrium of the GNEP.

(b) It is easy to prove that $V_{\alpha_k \beta_k} (x) \to 0$. Hence $x^{\infty}$ is a normalized Nash equilibrium of the GNEP.

The proof is completed. \qed
