A generalized gradient projection filter algorithm for inequality constrained optimization is presented. It has three merits. The first is that the amount of computation is lower, since the gradient matrix only needs to be computed once at each iterate. The second is that the paper uses the filter technique instead of any penalty function for constrained programming. The third is that the algorithm is of global convergence and locally superlinear convergence under some mild conditions.

1. Introduction

The optimal problems are often discovered in the field of management, engineering design, traffic transportation, national defence, and so on. The efficient algorithms for these problems are important. We will consider the following nonlinear inequality constrained optimization problem:

\[
\min_{\mathbf{x}} f(\mathbf{x}) \quad \text{s.t.} \quad c_j(\mathbf{x}) \leq 0, \quad j \in I,
\]

where \( I = \{1, 2, \ldots, m\} \) and \( \mathbf{x} \in \mathbb{R}^n \); assume that \( f : \mathbb{R}^n \to \mathbb{R} \) and \( c_j : \mathbb{R}^n \to \mathbb{R} \) are continuously differentiable.

In 2002, Fletcher and Leyffer [1] had proposed a filter method for nonlinear inequality constrained optimization, which did not require any penalty function. The main idea is that a trial point is accepted if it improves either the objective function or the constraint violation. Fletcher et al. [2, 3] and Gonzaga et al. [4] had proved that the method was of global convergence. More recently, this method has been extended by Wächter and Biegler [5, 6] and Chin [7] to line search method and by Su [8] to the SQP method.

In this paper, we modify the method given by Wang et al. [9] and propose a generalized gradient projection filter algorithm for inequality constrained optimization with arbitrary initial point. It is organized as follows. In Section 2, we first review the filter method and some definitions of generalized gradient projection and then introduce an algorithm for problem (1). The convergence and the rate of convergence on the algorithm are discussed in Sections 3 and 4, respectively. In the last section, we shall list the numerical tests.

2. Preliminaries and a Filter Algorithm

Let \( h(x) \) be a violation function; that is,

\[
h(x) = \max \left\{0, c_j(x), j \in I\right\}.
\]

Definition 1. A pair \((h(x_k), f(x_k))\) obtained on iteration \(k\) dominates another pair \((h(x_l), f(x_l))\) if and only if \(h(x_k) \leq h(x_l)\) and \(f(x_k) \leq f(x_l)\) hold.

Definition 2. A filter is a list of pairs \((h(x_k), f(x_k))\) such that no pair dominates any other. A pair \((h(x_k), f(x_k))\) is said to be acceptable for the filter if it is not dominated by any point in the filter.

We use \( F^{(k)} \) to denote the set of iterations indices \( j (j < k) \) such that \((h(x_j), f(x_j))\) is an entry in the current filter. A point \(x\) is said to be “acceptable for the filter” if and only if

\[
h(x) \leq (1 - \alpha^2 \eta) h(x_j) \quad \text{or} \quad f(x) \leq f(x_j) - y h(x_j)
\]

(3)
holds for all $j \in F^{(k)}$, where $\gamma, \eta \in (0,1)$ is close to zero and $\alpha$ is the step size. We may also “update the filter” which means that the pair $(h(x), f(x))$ is added to the list of pairs in the filter, and any pairs in the filter that are dominated by $(h(x), f(x))$ are removed.

However, relying solely on this criterion would result in convergence to a feasible but nonoptimal point. In order to prevent this, we employ the following sufficient reduction criterion.

We denote $\Delta f_k = f(x_k) - f(x_k + \alpha d_k)$ and $\Delta l_k = -\alpha Vf(x_k)^T d_k$ as actual reduction and linear reduction, respectively, at $f(x_k)$. The sufficient reduction condition for $f(x_k)$ takes the form

$$\Delta l_k \geq 0, \quad \Delta f_k \geq \sigma \Delta l_k,$$

where $\sigma \in (0,1/2)$ is a preassigned parameter.

At the current iterate $x_k$, define that $J(x_k) = \{ j \in I : \epsilon \leq c_j(x_k) - h(x_k) \leq 0 \}$, $A_k = (\nabla c_j(x_k), j \in J(x_k))$, and $c_j = (c_j(x_k), j \in J(x_k))^T$, then

$$d_k^0 = -P_k Vf(x_k) - B_k^T \lambda_k^0,$$

$$\lambda_k = -B_k Vf(x_k) + (A_k^T H_k A_k)^{-1} \lambda_k^1 + \lambda_k^2,$$

where $H_k$ is a given symmetric positive definite matrix, $\lambda_k^1 = -B_k Vf(x_k)$, $\lambda_k^2 = (A_k^T H_k A_k)^{-1} \lambda_k^1$, $B_k = (A_k^T H_k A_k)^{-1} A_k^T H_k$, and $P_k = H_k - H_k A_k B_k$.

Let $U_k = (u_k, j \in J(x_k))^T$, where $u_k = \begin{cases} \lambda_k^1, & \lambda_k^1 < 0 \\ 0, & \lambda_k^1 = 0 \end{cases}$. Set

$$d_k^1 = -P_k Vf(x_k) + B_k^T U_k$$

and

$$d_k^2 = -P_k Vf(x_k) + B_k^T \| e \|,$$

where $\epsilon = (1, \ldots, 1)^T$. Then

$$d_k = (1 - \rho_k) d_k^1 + \rho_k d_k^2,$$

where $\rho_k = \max(\rho \in [0,1] : \| Vf(x_k)^T (1 - \rho) d_k^1 + \rho d_k^2 \| \leq \theta \| Vf(x_k)^T d_k^1 \|, \theta \in (1/2, 1))$. We use correction direction $d_k$ if a trial point has been rejected.

The following is the algorithm.

Algorithm

(S0) Given start point $x_0 \in \mathbb{R}^n$, $e_0, e_1 > 0, \mu = h(x_0), \eta, \gamma \in (0,1)$, and $\beta, \sigma \in (0,1/2)$. Initialize the filter $\Phi_0 = [(\mu, +\infty)] \in \mathbb{R}^2$ and $F^{(0)} = \emptyset$. Set $k = 0$.

(S1) Inner loop A:

(S1.1) set $i = 0$ and $e_i = e_0$;

(S1.2) if det($A_k^T A_k$) $\geq e_k$, where $A_k = (\nabla c_j(x_k), j \in J_k)$ and $J_k = \{ j \in I : e_k \leq c_j(x_k) - h(x_k) \leq 0 \}$, then set $f(x_k) = J_k, A_k = A_k, \lambda_k = \lambda_k^1$, and $e_k = e_k$, and go to S2;

(S1.3) let $i = i + 1, e_i = e_{i-1}/2$, and go to S1.2.

(S2) Compute $d_k^0, \lambda_k$ by (5). If $d_k^0 = 0$ and $\lambda_k \geq 0$, then stop.

(S3) Test direction $d_k^0$:

(S3.1) if $\lambda_k \geq \epsilon_1$, and $x_k + d_k^0$ is acceptable for the filter, then go to S3.2; otherwise, go to S4;

(S3.2) if $h(x_k) > 0$, let $x_{k+1} = x_k + d_k^0$, and go to S7; otherwise, go to S3.3;

(S3.3) if $x_k + d_k^0$ satisfies the sufficient reduction condition (4), then let $x_{k+1} = x_k + d_k^0$, and go to S7; otherwise, go to S4.

(S4) Compute $d_k$ by (6) and set $\alpha = 1$.

(S5) Inner loop B:

(S5.1) if $x_k + \alpha d_k$ is acceptable for the filter, go to S5.2; otherwise, go to S5.3;

(S5.2) if $\Delta f_k < \sigma \Delta l_k$, go to S5.3; otherwise, go to S6;

(S5.3) set $\alpha = \alpha \sigma$, and go to S5.1.

(S6) Set $a_k = \alpha$ and $x_{k+1} = x_k + a_k d_k$.

(S7) Update filter $F^{(k)}$ to $F^{(k+1)}$. Update $H_k$ to $H_{k+1}$ by a quasi-Newton method. Set $k = k + 1$, and back to S1.

3. Global Convergence of the Algorithm

In this section, we assume that the following conditions hold.

(A1) $Vf(x), j \in J(x)$ is linearly independent of any $x \in \mathbb{R}^n$.

(A2) For any $k$ and $d$, $a \| d \|^2 \leq d^T H_k^{-1} d \leq b \| d \|^2$ holds, where $0 < a \leq b$ are constants.

(A3) Sequence $\{x_k\}$ generated by the algorithm remains in a closed, bounded subset $\Omega \subset \mathbb{R}^n$.

(A4) $f(x)$ and $c_i(x)$ ($i = 1, 2, \ldots, m$) are twice differentiable in $\Omega$; that is, $M_{\text{max}}^{i} \leq \lambda \| \nabla^2 f(x) \| \leq M_{\text{min}}^{i} \leq \lambda \| \nabla^2 c_i(x) \| \leq M_{\text{c}}^{i}$. Similar to [9], the following theorem and lemma hold.

Theorem 3. If $d_k^0 = 0$ and $\lambda_k \geq 0$ hold, then $x_k$ is a KKT point of (1).

Lemma 4. Consider

$$d_k^0 = 0, \quad \lambda_k \geq 0 \iff d_k^1 = 0.$$

According to [8], the following lemma holds.

Lemma 5. The inner loop A will terminate in finite times.

Lemma 6. If $x_k$ is not a KKT point of problem (1), there must exist $\nabla f(x_k)^T d_k < 0$ and $\nabla c_j(x_k)^T d_k < 0, j \in J(x_k)$.

Proof. Since $x_k$ is not a KKT point, we have either $d_k^0 \neq 0$ or $j \in J(x_k)$ such that $\lambda_k^1 < 0$. Thus

$$\nabla f(x_k)^T d_k \leq \theta \left[ - (d_k^0)^T H_k^{-1} d_k - \sum_{\lambda_k^1 < 0} (\lambda_k^1)^2 \right] < 0$$

(8)
it is easy to get that
\[ f(x_k + ad_k) \leq f(x_k) + \alpha \nabla f(x_k)^T d_k \]
\[ + \frac{1}{2} \alpha^2 M_{\max}^f \|d_k\|^2 \leq f(x_k) \]
\[ = f(x_k) - y h(x_k) , \]
\[ h(x_k + ad_k) \leq \max \left\{ 0, c_j (x_k) + \alpha \nabla c_j (x_k)^T d_k \right\} \]
\[ + \frac{1}{2} \alpha^2 M_{\max}^c \|d_k\|^2 \]
\[ \leq \max \left\{ 0, c_j (x_k) \right\} \]
\[ = (1 - \alpha^2 \eta) \max \left\{ 0, c_j (x_k) \right\} \]
\[ = (1 - \alpha^2 \eta) h(x_k) . \]

It proves that \( x_k + ad_k \) is acceptable for the filter.

Case 2 (\( h(x_k) > 0 \)). Similarly, when
\[ \alpha \leq \min \left\{ \frac{\nabla c_j (x_k)^T d_k}{(1/2) M_{\max}^c \|d_k\|^2 + \eta c_j (x_k)} \right\} , \] (15)
it is easy to learn that
\[ h(x_k + ad_k) \]
\[ \leq \max \left\{ 0, c_j (x_k) + \alpha \nabla c_j (x_k)^T d_k + \frac{1}{2} \alpha^2 M_{\max}^c \|d_k\|^2 \right\} \]
\[ \leq (1 - \alpha^2 \eta) h(x_k) . \] (16)

Since \( x_k \) is acceptable for the filter, so for all \( j \in F^{(k-1)}, h(x_k) \leq h(x_j) \) or \( f(x_k) \leq f(x_j) - y h(x_j) \) holds. From \( x_k + ad_k \) that is not acceptable for the filter, we have
\[ h(x_k + ad_k) > (1 - \alpha^2 \eta) h(x_j) , \] (17)
\[ f(x_k + ad_k) > f(x_j) - y h(x_j) \] (18)
hold. If \( h(x_k) \leq h(x_j) \), then
\[ h(x_k + ad_k) \leq (1 - \alpha^2 \eta) h(x_k) \leq (1 - \alpha^2 \eta) h(x_j) , \] (19)
which contradicts (17). If \( f(x_k) \leq f(x_j) - y h(x_j) \), then when
\[ \alpha \leq -\nabla f(x_k)^T d_k / (1/2) M_{\max}^f \|d_k\|^2 , \]
it is easy to learn that
\[ f(x_k + ad_k) \leq f(x_k) + \alpha \nabla f(x_k)^T d_k \]
\[ + \frac{1}{2} \alpha^2 M_{\max}^f \|d_k\|^2 \leq f(x_k) \] (20)
\[ \leq f(x_j) - y h(x_j) , \]
which contradicts (18).

Based on the above analysis, we can see that the claim holds. □
By the above statement, we can see that the algorithm is implementable. Now we turn on to prove the global convergence of the algorithm.

**Theorem 9.** Let the assumptions hold and $M_{\text{max}}^f > 0$. Suppose $x^\infty$ be the cluster point of $\{x_k\}$ generated by algorithm. There exist two possible cases. (i) The iteration terminates at a KKT point. (ii) Any accumulation point of $\{x_k\}$ is a KKT point.

**Proof.** we only need to prove case (ii). Since $x^\infty$ is the cluster point generated by algorithm, let $\{x_k\}_{k \in K}$ be any thinner subsequences converging to $x^\infty$.

We will first show that $x^\infty$ is a feasible point. Assume that $h(x_k) \to h(x^\infty) > 0$ for $k \in K$. Let $i$ and $j$ be any two adjacent indices in $K$ where $i < j$. If $h(x^\infty) > 0$, then there exists $k' \in K$ such that for all $i \geq k'$ and because $x_j$ is acceptable to the filter, we have

$$f(x_j) \leq f(x_i) - y h(x_i).$$

Since $\{f(x_k)\}_{k \in K}$ is a monotonically decreasing subsequence for $k \geq k'$ and is bounded below, therefore for $i, j \in K$, $i, j \geq k'$, and $i < j$,

$$\sum_{i \neq j \in K} \Delta f_{ij} = \sum_{i, j \in K} (f(x_i) - f(x_j))$$

is bounded above. However, since $f(x_j) \leq f(x_i) - y h(x_i)$, therefore by summing over all indices $i, j \in K$, $i, j \geq k'$, and $i < j$,

$$\sum_{i, j \in K} \Delta f_{ij} \geq \sum_{i \in K} h(x_i) \to +\infty,$$

which contradicts the fact that $\sum_{i \in K} \Delta f_{ij}$ is bounded above. Thus $h(x^\infty) = 0$, hence $x^\infty$ is feasible.

Next we need to show that $x^\infty$ is a KKT point. By the construction of algorithm, there are two cases: one generates the sequence $\{x_k\}$ from $x_{k+1} = x_k + d_k^0$, and the other generates it from $x_{k+1} = x_k + \alpha d_k^0$. We prove that claim according to the two cases.

**Case 1.** Suppose that there are infinite points gotten by $x_{k+1} = x_k + d_k^0$. Since $\Delta f_k \geq \sigma \Delta L_k$, we have

$$f(x_k) - f(x_k + d_k^0) = -\nabla f(x_k)^T d_k^0 - \frac{1}{2} (d_k^0)^T \nabla^2 f(y) d_k^0$$

$$\geq -\sigma \nabla f(x_k)^T d_k^0.$$

Thus $\nabla f(x_k)^T d_k^0 \leq -(1/2) (d_k^0)^T \nabla^2 f(y) d_k^0/(1 - \sigma)$ holds. Since $f$ is bounded below, then

$$+\infty > \sum_{k=0}^\infty f(x_k) - f(x_{k+1}) \geq -\sum_{k=0}^\infty \nabla f(x_k)^T d_k^0$$

$$\geq \sum_{k=0}^\infty \frac{(d_k^0)^T \nabla^2 f(y) d_k^0}{1 - \sigma} \geq \frac{M_{\text{min}}}{2(1 - \sigma)} \sum_{k=0}^\infty \|d_k^0\|^2.$$

Thus $\sum_{k=0}^\infty \|d_k^0\|^2 < +\infty$, which means $\|d_k^0\| \to 0$. Since $x^\infty$ is a feasible point, $x^\infty$ is a KKT point.

**Case 2.** Suppose that there are infinite points gotten by $x_{k+1} = x_k + \alpha d_k^0$. Since $\Delta f_k \geq \sigma \Delta L_k$, we have

$$0 = \lim_{k \to -\infty} f(x_k) - f(x_k + \alpha d_k^0)$$

$$\geq -\lim_{k \to -\infty} \sigma \nabla f(x_k)^T d_k \geq -\lim_{k \to -\infty} \nabla f(x_k)^T d_k \geq 0,$$

which means that $\nabla f(x_k)^T d_k \to 0$. Since

$$\nabla f(x_k)^T d_k \leq \theta \nabla f(x_k)^T d_k^0$$

$$\leq \theta \left[-(d_k^0)^T H_k d_k^0 - \sum_{k \leq 1} (\lambda_{kj}^0)^2 \right] < 0$$

we have $\|d_k^0\| \to 0$ and $\lambda_{kj} \geq 0$, and since $x^\infty$ is a feasible point, $x^\infty$ is a KKT point.

Combined Case 1 and Case 2, we can see that the claim holds. □

**4. The Rate of Convergence**

In this section, we discuss the convergent rate of the algorithm. We need the following strong assumptions.

(A5) The second-order sufficiently conditions hold, that is, $d_i^T \nabla^2 L(x^\infty, \lambda^\infty) d_i$ for all $d \in \ker \nabla c_i(x^\infty) \setminus \{0\}$, where $L(x, \lambda) = f(x) + \lambda^T c(x)$, $c(x) = (c_1(x), \ldots, c_m(x))^T$, $\Delta f(x, \lambda) = \{j \in f(x^\infty) : (\lambda^\infty)^T \lambda_j > 0\}$, and $(x^\infty, \lambda^\infty)$ is the KKT pair of problem (1).

(A6) Consider $\|H_k^{-1} - \nabla^2 L(x^\infty, \lambda^\infty)\| d_k^0 = 0(\|d_k^0\|)$.

**Theorem 10.** Suppose that assumptions (A1)–(A6) hold; then $x_{k+1} = x_k + d_k^0$ for large enough $k$. Therefore the algorithm is superlinearly convergent.

**Proof.** Suppose that $x_k$ is acceptable for the filter; we will show that for large enough $k$, $x_{k+1} = x_k + d_k^0$ is acceptable for the filter and satisfies the sufficient reduction condition.

First we need to prove that $x_{k+1} = x_k + d_k^0$ is acceptable for the filter. If $h(x_k + d_k^0) \leq (1 - \eta) h(x_k)$, then $x_{k+1} = x_k + d_k^0$ is already acceptable for the filter. Else we need to show that $f(x_k + d_k^0) \leq f(x_k) - y h(x_k)$. Let $s_k = f(x_k + d_k^0) - f(x_k) + y h(x_k)$; it holds that

$$s_k \leq \nabla f(x_k)^T d_k^0 + \frac{1}{2} (d_k^0)^T \nabla^2 f(x_k) d_k^0$$

$$+ \frac{\gamma h(x_k + d_k^0)}{1 - \eta} + o(\|d_k^0\|) \leq \nabla f(x_k)^T d_k^0$$

$$+ \frac{1}{2} (d_k^0)^T \nabla^2 f(x_k) d_k^0$$

$$+ \frac{\gamma}{2(1 - \eta)} \sum_{j=1}^m (d_k^0)^T \nabla^2 c_j(x_k) d_k^0 + o(\|d_k^0\|).$$

Thus $\sum_{k=0}^\infty S_k < +\infty$, which means $\|d_k^0\| \to 0$. Since $x^\infty$ is a feasible point, $x^\infty$ is a KKT point.
From \( \nabla f(x_k)^T d_k = \lambda_k^T c_k - (d_k)^T H_k^{-1} d_k \), we have

\[
s_k \leq \lambda_k^T c_k - (d_k)^T H_k^{-1} d_k + \frac{1}{2} (d_k)^T \nabla^2 f(x_k) d_k + \frac{1}{2} \sum_{j=1}^{m} \lambda_j (d_k)^T \nabla^2 c_j (x_k) d_k + o \left( \|d_k\|^2 \right) - \frac{\gamma}{2} \sum_{j=1}^{m} \lambda_j (d_k)^T \nabla^2 c_j (x_k) d_k + o \left( \|d_k\|^2 \right).
\]  

Since \( \lambda_{kj} \geq \epsilon_j \), set \( \epsilon_j = \gamma / (1 - \eta) \), and then

\[
s_k \leq \lambda_k^T c_k - (d_k)^T H_k^{-1} d_k + \frac{1}{2} (d_k)^T \nabla^2 f(x_k) d_k + o \left( \|d_k\|^2 \right) - \frac{\gamma}{2} \sum_{j=1}^{m} \lambda_j (d_k)^T \nabla^2 c_j (x_k) d_k + o \left( \|d_k\|^2 \right).
\]  

According to \( x_k \to x^\infty \), \( \lambda_k \to \lambda^\infty \geq 0 \), and assumptions (A2), (A3), and (A5), then

\[
s_k \leq -\frac{a}{2} \|d_k\|^2 + \frac{1}{2} (d_k)^T (\nabla^2 L(x_k, \lambda_k) - \nabla^2 L(x^\infty, \lambda^\infty)) d_k + o \left( \|d_k\|^2 \right) + o \left( \|d_k\|^2 \right) \leq 0.
\]

Hence, for large enough \( k \), \( x_{k+1} = x_k + d_k \) is acceptable for the filter.

Now we are going to show that when \( k \) is large enough, \( x_{k+1} = x_k + d_k \) satisfies the sufficient reduction condition \( \Delta f_k \geq \sigma \Delta L_k \). Let \( t_k = f(x_k) - f(x_k + d_k) - \sigma \Delta L_k \); then we have

\[
t_k \geq (\sigma - 1) (\lambda_k^T c_k - (d_k)^T H_k^{-1} d_k) - \frac{1}{2} (d_k)^T \nabla^2 f(x_k) d_k - o \left( \|d_k\|^2 \right) - \frac{1}{2} (d_k)^T \nabla^2 L(x_k, \lambda_k) d_k + o \left( \|d_k\|^2 \right).
\]

Since \( c_j(x_k) \to c_j(x^\infty) \leq 0 \) and assumptions (A3), and (A5), then

\[
t_k \geq (\sigma - 1) \lambda_k^T c_k - \frac{1}{2} (d_k)^T H_k^{-1} d_k - \frac{1}{2} (d_k)^T (\nabla^2 L(x_k, \lambda_k) - \nabla^2 L(x^\infty, \lambda^\infty)) d_k - \frac{1}{2} (d_k)^T (\nabla^2 L(x^\infty, \lambda^\infty) - H_k^{-1}) d_k - o \left( \|d_k\|^2 \right)
\]

\[
\geq \frac{a}{2} \left( \frac{1}{2} - \sigma \right) \|d_k\|^2 - o \left( \|d_k\|^2 \right) \geq 0.
\]

Hence, for large enough \( k \), \( x_{k+1} = x_k + d_k \) satisfies the sufficient reduction condition \( \Delta f_k \geq \sigma \Delta L_k \). □

Based on Theorem 10, we can see, when \( k \) is large enough that the algorithm will implement the Newton steps and will not change; thus the algorithm is superlinearly convergent.

### 5. Numerical Test

In this section, we give some numerical results according to our algorithm. We update the matrix \( H_k \) by BFGS formulation and the algorithm parameters are set as \( H_0 = I \in R^{n \times n} \), \( y = 0.1 \), \( \eta = 0.1 \), and \( \sigma = 0.01 \).

**Example 11.** One has

\[
\min \ f(x) = 0.1 \left\{ \frac{0.44 x_1^2}{x_2^2} + \frac{10}{x_1} + \frac{0.592}{x_2} \right\}
\]

s.t. \( -1 + 8.62 \frac{x_2}{x_1} \leq 0 \),

where \( x_0 = (2.5, 2.5) \), \( x^\infty = (1.2867, 0.5305) \), and iterate = 16.

**Example 12 (see [8]).** Consider

\[
\min \ f(x) = x_1^2 + x_2^2 + x_3^2 + x_4^2
\]

s.t. \( 6 - x_1^2 - x_2^2 - x_3^2 - x_4^2 \leq 0 \),

where \( x_0 = (2, 2, 2, 2) \), \( x^\infty = (1.2247, 1.2247, 1.2247, 1.2247) \), and iterate = 14.

**Example 13 (see [10]).** One has

\[
\min \ f(x) = -50 \left( x_1^2 + x_2^2 + x_3^2 + x_4^2 + x_5^2 \right)
\]

s.t. \( 10x_1 - 7.5x_2 - 3.5x_3 - 2.5x_4 - 1.5x_5 - 10x_6 \leq 0 \),

\( 6x_1 + 3x_2 + 3x_3 + 2x_4 + x_5 \leq 6.5 \),

\( 10x_1 + 10x_2 + 5x_3 \leq 20 \),

\( 0 \leq x_i \leq 1 \), \( i = 1, 2, 3, 4, 5 \); \( x_6 \geq 0 \).

The \( x^\infty \) is a minimizer with an objective value \( f^* = -361.5 \). We choose the initial point \( x_0 = (1, 1, 1, 1, 1, 10) \), iterate = 6.
Example 14 (see [11]). Consider

$$\begin{align*}
\min & \quad f(x) = x_1^2 + x_2^2 + x_3^2 + x_4^2 - 5x_1 - 5x_2 - 21x_3 - 7x_4 \\
\text{s.t.} & \quad x_1^2 + x_2^2 + x_3^2 + x_4^2 + x_1 - x_2 + x_3 - x_4 - 8 \leq 0 \\
& \quad x_1^2 + 2x_2^2 + x_3^2 + 2x_4^2 + x_1 - x_4 - 9 \leq 0 \\
& \quad 2x_1^2 + x_2^2 + x_3^2 + 2x_4^2 - x_2 - x_4 - 5 \leq 0.
\end{align*}$$

(37)

We choose the initial point $x_0 = (1, 1, 1, 1)$. $x^{\infty} = (0.2896, 0.9150, 2.1798, 0.6265)$ is a minimizer with an objective value $f^* = -50.1192$, iterate $= 40$.
