1. Introduction

Semidefinite optimization has been successfully applied to deal with many important problems [1–10] since it was proposed in 1963 [11]. Recently, the authors in [10] presented the semidefinite optimization method for obtaining guaranteed bounds on linear functionals defined on solutions of linear differential equations with polynomial coefficients. Instead of directly handling linear differential equations, the approach gets the discussed bounds by solving SDPs based on these equations and related functionals. Their numerical results are very encouraging. The authors in [12] proposed the semidefinite optimization method for estimating bounds on linear functionals of solutions of linear integral and integrodifferential equations with polynomial kernels. The method does not directly solve these equations as successive approximations method, Runge-Kutta one, direct computation one, the Adomian decomposition one, the modified Adomian decomposition one, the variational iterative one, and so forth in the references [13–21]. Numerical results show that the proposed method can get guaranteed bounds on the discussed functionals.

In this paper, we will extend the polynomial kernels in [12] to the generally smooth kernels and propose semidefinite optimization method for providing guaranteed bounds on linear functionals defined on solutions of Fredholm and Volterra integral equations with generally smooth kernels. Firstly, we expand smooth kernel in Fredholm or Volterra integrodifferential equation as a series of Taylor polynomials, and then the Fredholm or Volterra integral equation with the smooth kernel is converted to a series of integral equations with polynomial kernels. Secondly, semidefinite programs (SDPs) are constructed based on these approximative equations and discussed functionals. Thirdly, we apply SeDuMi 1.1R3 [22] to solve these SDPs and get upper and lower bounds series which all converge to the exact value of related functional. Finally, we illustrate the effectiveness of the method by carrying out some numerical experiments.

The rest of this paper is organized as follows. In Section 2, we propose semidefinite optimization method for estimating guaranteed bounds on the linear functionals defined on solution of Volterra integral equation of the second kernel with smooth kernel. In Section 3, four numerical examples
are tested. We end the paper with some conclusions and discussions in the final section.

## 2. Semidefinite Optimization Method

In this section, we propose semidefinite optimization method for estimating guaranteed bounds on linear functionals defined on solutions of Volterra integral equation of the second kind with smooth kernel.

Throughout the work, we suppose that related integral equations make unique solutions exist in the distribution space $\mathcal{D}$, in which the polynomial ring $\mathbb{R}[x]$ is dense.

### Primal Problem

Computing

$$
\int_0^1 x^j \phi(x) \, dx
$$

in which $\phi(x)$ satisfies

$$
\phi(x) = f(x) + \int_0^x K(x, s) \phi(s) \, ds,
$$

where $f(x)$ and the kernel $K(x, s)$ are given in advance, and the latter is an infinitely smooth function in variables $x$ and $s$.

Equation (2) is called Volterra integral equation of the second kind [17].

We expand the kernel $K(x, s)$ as the following Taylor polynomial with orders $n$ at $x = 0$ and $s = 0$:

$$
K(x, s) = K_n(x, s) + R_n(x, s),
$$

where

$$
K_n(x, s) = K(0, 0) + \frac{1}{1!} \left( x \frac{\partial}{\partial x} + s \frac{\partial}{\partial s} \right) K(0, 0) + \frac{1}{2!} \left( x \frac{\partial}{\partial x} + s \frac{\partial}{\partial s} \right)^2 K(0, 0) + \cdots + \frac{1}{n!} \left( x \frac{\partial}{\partial x} + s \frac{\partial}{\partial s} \right)^n K(0, 0),
$$

$$
R_n(x, s) = \frac{1}{(n + 1)!} \left( x \frac{\partial}{\partial x} + s \frac{\partial}{\partial s} \right)^{n+1} K(\theta x, \theta s), \quad 0 \leq \theta \leq 1,
$$

$$
\left( x \frac{\partial}{\partial x} + s \frac{\partial}{\partial s} \right)^i K(0, 0) = \sum_{r=0}^{i} C_i^r \left( \frac{\partial}{\partial x} \right)^{i-r} \left( \frac{\partial}{\partial s} \right)^r K(0, 0),
$$

Therefore, (2) can be approximated by the following integral equation:

$$
\phi(x) = f(x) + \int_0^x K_n(x, s) \phi(s) \, ds,
$$

in which $K_n(x, s)$ is of the form (4).

For simplicity, we rewrite $K_n(x, s)$ in (4) as

$$
K_n(x, s) = \sum_{j=0}^{n} \sum_{j=0}^{n} h_{ij} x^j.
$$

Further, *Primal Problem* can be written as the approximative form.

### Approximative Problem

Compute

$$
\int_0^1 x^j \phi(x),
$$

where $\phi(x)$ satisfies (7), in which $f(x)$ is just the one in (2) and the kernel $K_n(x, s)$ is defined by (8).

In [12], semidefinite optimization method has been proposed for estimating bounds on linear functionals defined on solution of linear integral equation with polynomial kernel. Now we present semidefinite optimization method for providing guaranteed bounds on the linear functional (1) in *Primal Problem*, which is a generalized form of the method proposed in [12].

### Algorithm 1.

**Step 0.** Let $n = 1, N = 1$ and give a tolerance $\epsilon$.

**Step 1.** Convert *Primal Problem* to *Approximative Problem* according to the above analysis.

**Step 2.** Generate linear equality constraints.

Suppose that the solution $\phi(x)$ of (7) is bounded from below; that is, there exists $c$ such that

$$
\phi(x) \geq c, \quad \forall x \in [0, 1].
$$

We define

$$
m_i = \int_0^1 x^i (\phi(x) - c), \quad i = 0, 1, 2, \ldots
$$

which may be called moments even though $\phi(x)$ may not be a probability distribution.

Multiplying (2) by the testing functions $\tau(x) = x^l, l = 0, 1, 2, \ldots$ and integrating it over the interval $[0, 1]$, we can get

$$
\int_0^1 x^j \phi(x) = \int_0^1 x^j f(x) + \int_0^1 x^j \int_0^x K_n(x, s) \phi(s) \, ds \, dx
$$

$$
= \int_0^1 x^j f(x) + \sum_{l=0}^{n} \int_0^1 \left( \int_0^x \left( \sum_{l=0}^{n} h_{ij} x^{i+l} \right) \phi(s) \, ds \right) \, dx
$$

$$
= \int_0^1 x^j f(x) + \sum_{l=0}^{n} \sum_{i=0}^{n} h_{ij} \int_0^1 x^{i+l} \phi(s) \, ds \, dx
$$

$$
\times \left( \int_0^1 s^j \phi(s) \, ds - \int_0^1 s^j x^l \phi(s) \, ds \right).
$$

(12)
By (11), we obtain
\[ \int_0^1 x^i \phi(x) = m_i + \frac{c}{i+1}. \]  
(13)

Substituting (13) into (12), we can get
\[ m_i + \sum_{j=0}^{n} \alpha_j m_j + \sum_{j=0}^{n} \sum_{j=0}^{n} v_{ij} m_{j+l+1} = \beta_i, \]  
(14)
in which
\[ \alpha_j = -\sum_{j=0}^{n} \frac{h_{ij}}{j + l + 1}, \]
\[ v_{ij} = \frac{h_{ij}}{j + l + 1}, \]  
(15)
\[ \beta_i = \frac{c}{l+1} + \int_0^1 f(x). \]

Because the solution \( \phi(x) \) of (2) is in the distribution space \( \mathcal{A} \), in which \( \mathbb{R}[x] \) is dense, (7) can be transformed into the system which consists of the equations as described by (14) where \( l = 0, 1, 2, \ldots \).

**Step 3.** Generate semidefinite constraints.

It is obvious that \( x \in [0, 1] \) is equivalent to \( x \in \{ x | f_1(x) \geq 0, f_2(x) = 1 - x \geq 0 \} \).

Denote
\[ F_M(x) = \left[ 1 \ x \ x^2 \ \cdots \ x^M \right]^T, \]  
(16)
where \( M \) is a nonnegative integer.

By the method in [10], for \( x \in [0, 1] \), we have
\[ \int_0^1 (\phi(x) - c) F_M(x) F_M(x)^T \prod_{j \in \mathcal{S}} f_j(x) \geq 0, \quad \mathcal{S} \subseteq \{ 1, 2 \}. \]  
(17)

We can obtain the following positive semidefinite matrices:
\[ Q_0 \geq 0, \quad Q_1 \geq 0, \]  
(18)
in which
\[ Q_0 = \begin{pmatrix} m_0 & m_1 & \cdots & m_M \\ m_1 & m_2 & \cdots & m_{M+1} \\ \vdots & \vdots & \ddots & \vdots \\ m_M & m_{M+1} & \cdots & m_{2M} \end{pmatrix}, \]
\[ Q_1 = \begin{pmatrix} m_1 & m_2 & \cdots & m_{M+1} \\ m_2 & m_3 & \cdots & m_{M+2} \\ \vdots & \vdots & \ddots & \vdots \\ m_{M+1} & m_{M+2} & \cdots & m_{2(M+1)} \end{pmatrix}, \]  
(19)
where \( M = 2n + N + 1 \) in the three matrices \( Q_0, Q_1, \) and \( Q_2 \), by replacing \( \int_0^1 (\phi(x) - c) x^i \) in (17) with \( m_i \) and setting the four subsets of the set \{ 1, 2 \} to \( \mathcal{S} \) in (17), respectively.

**Step 4.** Construct two SDPs.

Assuming that the testing function with the highest degree is \( x^N \), we get the following two SDPs:
\[
\begin{align*}
\text{max} / \text{min} & \quad m_i + \frac{c}{i+1}, \\
\text{s.t.} & \quad (14), \quad l = 0, 1, \ldots, N, \quad (20) \\
& \quad (18),
\end{align*}
\]
where decision variables are \( m_i, i = 0, 1, 2, \ldots, 2(M + 2) \).

**Step 5.** Apply SeDuMi 1.1R3 to solve the two SDPs.

Denote by \( m_i^{(\max,N,n)} \) the decision variable \( m_i \) obtained by solving the above maximizing programming. \( m_i^{(\min,N,n)} \) has similar meaning.

**Step 6.** Define whether the highest degree \( N \) of the testing function increases or not.

When \( N = 1 \), go to Step 7; or if
\[
\begin{align*}
\left| m_i^{(\max,N,n)} - m_i^{(\max,N-1,n)} \right| \leq \epsilon, & \quad i = 0, 1, \ldots, 2n + N + 1, \\
\left| m_i^{(\min,N,n)} - m_i^{(\min,N-1,n)} \right| \leq \epsilon, & \quad i = 0, 1, \ldots, 2n + N + 1
\end{align*}
\]  
(21)
all hold, go to Step 7, or let \( N := N + 1 \) and go to Step 4.

**Step 7.** Judge whether iteration goes on or not.

When \( n = 1 \), go to Step 2, or if
\[
\begin{align*}
\left| m_i^{(\max,N,n)} - m_i^{(\max,N,n-1)} \right| \leq \epsilon, & \quad i = 0, 1, \ldots, 2n + N + 1, \\
\left| m_i^{(\min,N,n)} - m_i^{(\min,N,n-1)} \right| \leq \epsilon, & \quad i = 0, 1, \ldots, 2n + N + 1
\end{align*}
\]  
(22)
all hold, stop the iteration and output \( m_i^{(\max,N,n)} \) and \( m_i^{(\min,N,n)} \), which are upper and lower bounds of \( \int_0^1 x^i \phi(x) \), respectively; or let \( n := n + 1 \) and go to Step 1.

**Remark 2.** Obviously, \( x \in [0, 1] \) in Algorithm 1 can extend to \( x \in [a, b] \) with \( a < b \). Of course, some necessary modifications must be done.

**Remark 3.** The proposed method is also suitable for other linear integral and integrodifferential equations with smooth kernels.

**Remark 4.** In general, \( c \) in (5) is unknown. But we do not need infimum of \( \phi(x) \) over \([0, 1]\), so we can set a small value to \( c \).

**Remark 5.** The semidefinite constraints (18) in Algorithm 1 only depend on the integral interval \([0, 1]\). The moments \( m_{2n+1}, m_{2n+2}, \ldots, m_3 \) in the semidefinite constraints (18) do not appear in the linear constraints. They are extension moments (see [9] or [10] for details).
Remark 6. In practical applications, for reducing computation amounts of Algorithm 1, we usually set two suitable positive integers to \( n \) and \( N \), respectively.

Remark 7. In some cases, \( K(x, s) \) in (2) can also be expanded as Taylor polynomials in variables \( x \) and \( s \) with different orders, respectively.

### 3. Numerical Experiments

In this section, we give four examples to illustrate the effectiveness of Algorithm 1. For simplicity, the interval \([0, 1]\) is always taken as the integral interval in these examples.

#### 3.1. Volterra Integral Equation of the First Kind with Smooth Kernel

**Example 1.** Computing

\[
\int_{0}^{1} x^j \phi(x),
\]

where \( \phi(x) \), satisfies

\[
\int_{0}^{x} \left( \cos x + e^t \right) \phi(t) dt = \frac{-1}{2} + \frac{1}{2} e^x \cos x + \frac{1}{2} e^x \sin x + \sin x \cos x.
\]  

(24)

The exact solution of (24) is \( \phi(x) = \cos x \).

Multiplying (24) by \( x^i \) and integrating it over the interval \([0, 1]\), we can get

\[
\int_{0}^{1} \left( \int_{0}^{x} x^i \left( \cos x + e^t \right) \phi(t) dt \right) dx = \int_{0}^{1} \left( \frac{-1}{2} + \frac{1}{2} e^x \cos x + \frac{1}{2} e^x \sin x + \sin x \cos x \right) x^i.
\]  

(25)

In this example, \( u(x) \geq 0 \) for all \( x \in [0, 1] \). Zero is set to \( c \) in (11). Then we define

\[
m_i = \int_{0}^{1} x^i \phi(x). \]

(26)

Taylor polynomial with degree 6 of \( \cos x \) at \( x = 0 \) and Taylor polynomial with degree 7 of \( e^t \) at \( t = 0 \) are as follows:

\[
\cos x \approx g_1(x) = a_0 + a_1 x^2 + a_2 x^4 + a_3 x^6,
\]

\[
e^t \approx g_2(t) = b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7,
\]

where \( a_0 = 1, a_1 = -1/2, a_2 = 1/24, a_3 = -1/720, b_0 = 1, b_1 = 1, b_2 = 1/2, b_3 = 1/6, b_4 = 1/24, b_5 = 1/120, b_6 = 1/720, \) and \( b_7 = 1/5040 \), respectively.

**Table 1:** Upper and lower bounds for Example 1 for \( N = 28 \).

</tbody>
</table>

Substituting (27) into (25) and replacing \( \int_{0}^{1} t^i \phi(t) dt \) with \( m_i \), we can obtain

\[
\begin{align*}
&\left( \frac{a_0}{i+1} + \frac{a_1}{i+3} + \frac{a_2}{i+5} + \frac{a_3}{i+7} + \frac{b_0}{i+1} \right) m_0 \\
&+ \frac{b_1}{i+1} m_1 + \frac{b_2}{i+1} m_2 + \frac{b_3}{i+1} m_3 \\
&+ \frac{b_4}{i+1} m_4 + \frac{b_5}{i+1} m_5 + \frac{b_6}{i+1} m_6 + \frac{b_7}{i+1} m_7 \\
&- \left( \frac{a_0}{i+1} + \frac{a_1}{i+1} \right) m_{i+1} - \frac{b_1}{i+1} m_{i+2} \\
&- \left( \frac{b_0}{i+1} + \frac{a_1}{i+3} \right) m_{i+3} - \frac{b_3}{i+1} m_{i+4} \\
&- \left( \frac{b_2}{i+1} + \frac{a_2}{i+5} \right) m_{i+5} - \frac{b_5}{i+1} m_{i+7} \\
&- \frac{b_7}{i+1} m_{i+6} - \frac{b_8}{i+1} m_{i+8} \\
&= \int_{0}^{1} \left( \frac{1}{2} + \frac{1}{2} e^x \cos x + \frac{1}{2} e^x \sin x + \sin x \cos x \right) x^i.
\end{align*}
\]  

(28)

For \( x \in [0, 1] \), we know that the semidefinite constraints are the same as (18).

We construct the following two SDPs:

\[
\begin{align*}
&\text{max} / \text{min} \quad m_i \\
&\text{s.t.} \quad (28) , \quad i = 0, 1, \ldots, N, (29)
\end{align*}
\]  

(18)

Letting \( N = 28 \), we apply SeDuMi 1.1R3 to solve the max/min SDPs. The partial numerical results are reported in Table 1.

In Table 1, UN-Ob, LLFoS, ULFoS, and ELFoS mean decision variables or objective functions in the above two

</table>

SDPs, lower bounds, upper bounds, and exact values on linear functionals defined on solution of (24), respectively. Error means $|ULFoS - ELFoS|$. These signs in Tables 2, 3, 4, and 5 have the same meanings. From Table 1, we can see that for every $m_i, |ULFoS - ELFoS|$ is more than $10^{-3}$, and these errors do not decrease as $N$ increases. Maybe the case is resulted in by accumulative error.

In order to increase the precision of numerical results of Example 1, we first convert (24) to the following equivalent integral equation (30) and then apply Algorithm 1 to estimate (23), where $\phi(x)$ satisfies (30).

Differentiating both sides of (24) with respect to $x$ gives

$$
(\cos x + e^x) \phi(x) = \int_0^x \sin x \phi(t) \, dt
$$

(30)

$$
= \cos x \cdot e^x + \cos^2 x - \sin^2 x.
$$
Use the two polynomials
\[
\cos x + e^x = g_1(x) = a'_0 x + a'_1 x + a'_2 x^3
\]
\[
+ a'_3 x^4 + a'_4 x^5 + a'_5 x^7,
\]
where \(a'_0 = 2, a'_1 = 1, a'_2 = 1/6, a'_3 = 1/12, a'_4 = 1/120, a'_5 = 1/3024, b'_0 = 0.9973, \) and \(b'_1 = -0.1563,\) to approximate \(\cos x + e^x\) and \(\sin x,\) respectively.

Substituting (31) into (30), multiplying its both sides by \(x^j,\) and integrating it over the interval \([0, 1]\), we have
\[
\int_0^1 g_1(x) x^j \phi(x) - \int_0^1 \left( x^j g_2(x) \int_0^1 \phi(t) dt \right) dx
= \int_0^1 \left( \cos x \cdot e^x + \cos^2 x - \sin^2 x \right) x^j.
\]

Let
\[
m_i = \int_0^1 x^j \phi(x).
\]
Substituting (33) into (32) and simplifying it, we get
\[
- \left( \frac{b'_0}{i + 2} + \frac{b'_1}{i + 4} \right) m_0 + a'_0 m_1 + a'_1 m_{i+1}
+ b'_1 m_{i+2} + a'_2 m_{i+3} + b'_1 m_{i+4}
+ a'_3 m_{i+5} + a'_4 m_{i+7}
= \int_0^1 \left( \cos x \cdot e^x + \cos^2 x - \sin^2 x \right) x^j.
\]

According to \(x \in [0, 1],\) we have semidefinite optimization as stated by (18).

We construct the SDPs:
\[
\begin{align*}
\text{max} / \text{min} & \quad m_i \\
\text{s.t.} & \quad (34), \quad i = 0, 1, \ldots, N, \\
& \quad (18).
\end{align*}
\]

Letting \(\epsilon = 10^{-8}\) and \(N = 50,\) we apply SeDuMi 1.1R3 to solve the above SDPs. Some numerical results are listed in Table 2.

From Table 2 we can see that the numerical results are accurate to four decimal points of the related exact values. Numerical results in Table 2 show that the proposed approach can efficiently estimate upper and lower bounds on the linear functionals \(\int_0^1 x^j \phi(x)\) defined on solution of Volterra integral equation of the first kind. If we want to increase precision of the numerical results, we can reach the goal by expanding \(\cos x\) and \(e^x\) in the kernel of (24) as Taylor polynomials with higher degrees. We also solved the max/min programs when \(N = 49.\) Numerical results show that \(|m_i^{(\text{max},50,7)} - m_j^{(\text{max},49,7)}|\) and \(|m_j^{(\text{min},50,7)} - m_j^{(\text{min},49,7)}|, j = 0, 1, \ldots, 40,\) are all less than \(10^{-5}\). So the examples are as follows.

3.2. Volterra Integral Equation of the Second Kind with Smooth Kernel

Example 2. Computing
\[
\int_0^1 x^j \phi(x),
\]
where \(\phi(x)\), satisfies
\[
\phi(x) = \int_0^1 \left( 1 + x e^t \right) \phi(t) dt + 2x - \frac{1}{3} x^3 - x^3 e^x.
\]

The exact solution of the equation is \(\phi(x) = x^2 + 2x.\) Define \(m_i\) as stated by (26). We expand \(e^x\) as follows:
\[
e^x = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4,
\]
where \(a_0 = 1, a_1 = 1, a_2 = 1/2, a_3 = 1/6,\) and \(a_4 = 1/24.\)

Multiplying (37) in which \(xe^x\) is replaced with \(x(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4)\) by \(x^j\) and integrating it over the interval \([0, 1],\) we can get
\[
\begin{align*}
- \left( \frac{1}{i + 1} + \frac{1}{i + 2} \right) m_0 - \frac{a_1}{i + 1} m_1 - \frac{a_2}{i + 1} m_2 \\
- \frac{a_3}{i + 1} m_3 - \frac{a_4}{i + 1} m_4 - \frac{a_5}{i + 1} m_5 \\
- \frac{a_6}{i + 1} m_6 - \frac{a_7}{i + 1} m_7 - \frac{a_8}{i + 1} m_8 - \frac{a_9}{i + 1} m_9 \\
+ \frac{a_0}{i + 2} m_{i+2} + \frac{a_1}{i + 2} m_{i+3} + \frac{a_2}{i + 2} m_{i+4} \\
+ \frac{a_3}{i + 2} m_{i+5} + \frac{a_4}{i + 2} m_{i+6} + \frac{a_5}{i + 2} m_{i+7} \\
+ \frac{a_6}{i + 2} m_{i+8} + \frac{a_7}{i + 2} m_{i+9} \\
= \int_0^1 \left( 2x - \frac{1}{3} x^3 - x^3 e^x \right) x^j.
\end{align*}
\]

Because \(x \in [0, 1],\) we obtain semidefinite constraints as stated by (18).

We construct the following SDPs:
\[
\begin{align*}
\text{max} / \text{min} & \quad m_i \\
\text{s.t.} & \quad (39), \quad i = 0, 1, \ldots, N, \\
& \quad (18).
\end{align*}
\]

Letting \(\epsilon = 10^{-8}\) and \(N = 50,\) we apply SeDuMi 1.1R3 to solve the above SDPs. The partial numerical upper and lower bounds are listed in Table 3.

Numerical results in Table 3 show that the proposed method is very effective for obtaining guaranteed upper and lower bounds whose precision can reach \(10^{-5}.\)
3.3. Fredholm Integral Equation of the Second Kind with Smooth Kernel

Example 3. Computing

\[ \int_0^1 x^i \phi(x), \]  

where \( \phi(x) \), satisfies

\[ \phi(x) = \int_0^1 \left( x^2 \sin t + 4 \cos t \right) \phi(t) \, dt \]
\[ + \frac{1 - \cos 1}{2} x^2 - x - 3 + 2 \sin 1. \]  

The exact solution of (42) is \( \phi(x) = (x^2/2) - x + 1 \)

Chebyshev polynomial with degree 3 of \( \sin t \) at \( t = 0 \) and

Chebyshev polynomial with degree 4 of \( \cos t \) at \( t = 0 \) are as follows:

\[ \sin t \approx 0.9974t - 0.1563t^3, \]
\[ \cos t \approx 1.0005 - 0.5040t^2 + 0.0440t^4. \]

(43)

Define \( m_i \) as (26). Substituting (43) into (42), multiplying (42) by \( x^i \), and integrating it over the interval \([0, 1]\), we have

\[ m_i - \frac{0.9974}{i + 3} m_1 + \frac{0.1563}{i + 3} m_3 - \frac{4.002}{i + 1} m_0 \]
\[ + \frac{2.016}{i + 1} m_2 - \frac{0.176}{i + 1} m_4 \]
\[ = \frac{1 - \cos 1}{2 (i + 3)} - \frac{1}{i + 2} - \frac{3 - 2 \sin 1}{i + 1}. \]  

(44)

For \( x \in [0, 1] \), we get semidefinite constraints as stated by (18).

We construct the following SDPs:

\[ \max / \min m_i \]

s.t. \( (44), \ i = 0, 1, \ldots, N, \)  

\[ (18). \]  

(45)

Letting \( \epsilon = 10^{-8} \) and \( N = 50 \), we apply SeDuMi 1.1R3 to solve the above SDPs and get numerical upper and lower bounds of related functionals which are partially listed in Table 4.

Obviously, the numerical results in Table 4 are accurate to four decimal points of the exact functional values.

3.4. Volterra Integrodifferential Equation with Smooth Kernel

Example 4. Computing

\[ \int_0^1 x^i \phi(x), \]  

where \( \phi(x) \), satisfies

\[ \phi'(x) - \int_0^x (e^x + 2) \phi(t) \, dt = 2 - e^{2x}, \]

with boundary condition \( \phi(0) = 1. \)  

The exact solution of (47) is \( \phi(x) = e^x. \)

Integrating (47) over the interval \([0, 1]\), we get

\[ \phi(x) - \int_0^x (e^x + 2x - e^t - 2t) \phi(t) \, dt = 2x - \frac{e^{2x}}{2} + \frac{3}{2}. \]

(48)

Replace \( e^t \) in the kernel of (48) with (38), and do the similar replacement for \( e^x \) in the kernel. Applying SeDuMi 1.1R3 to solve the corresponding approximative problem which is just Volterra integral equation of the second kind, we get numerical results partially reported in Table 5.

Numerical results in Table 5 show that the semidefinite optimization method can provide guaranteed bounds on linear functionals defined on solution of (47). If we hope to obtain more accurate numerical results, we can expand \( e^t \) and \( e^x \) in the kernel of (47) as Taylor polynomials with higher degrees.

4. Conclusions and Discussions

In this paper, we have presented the semidefinite optimization method for providing guaranteed bounds on linear functionals defined on solutions of linear integral equations with smooth kernels. Four examples show that the proposed approach is effective for estimating bounds on linear integral and integrodifferential equations with smooth kernels. The proposed approach requires that the related integral equation is linear. It cannot be directly applied to solve the nonlinear integral equation. So next work is to improve the proposed method, so that it can handle nonlinear problems.
