We study the well-posedness of a 3D nonlinear stochastic wave equation which derives from the Maxwell system by the Galerkin method. Then we study the approximate controllability of this system by the Hilbert uniqueness method.

1. Introduction

Many physical models are described by wave equations, such as the scalar wave equations, the elastic wave equations, and Maxwell’s equations. Therefore, the well-posedness and controllability of wave equations are both important issues in theories and applications.

The well-posedness of partial differential equations (PDEs) has been studied by many authors; there are some useful methods: the semigroup theory [1–4], the fixed point method [5, 6], the variational method [7], and the regularization method [8]. In this paper, we study the well-posedness of the 3D nonlinear stochastic equation by the Galerkin method. In order to use this method, we have to establish the basis of the $L^2(G)^3$, via the Hilbert-Schmidt theorem.

The controllability of PDEs has been a very active research field since 1960s. From [9], we can know the definitions of exact controllability, null controllability, and approximate controllability. From the definition of controllability, we should consider a final condition problem in PDE rather than an initial condition problem. In fact, the problem of controllability is related to the solution of the backward adjoint problem. The connection of these two problems is the famous Hilbert uniqueness method (HUM), proposed by Lagnese. From [10], we know that “the theoretical basis of HUM is, roughly speaking, the observation that if one has uniqueness of solutions for a linear evolutionary system in a Hilbert space it is possible to introduce a Hilbert space norm $\|\cdot\|_F$ based on the uniqueness property in such a way that the dual system is exactly controllable to the dual space $F'$. The exact controllability problem is thereby transferred to the problem of identifying (or otherwise characterizing) the couple $F, F'$. The latter is essentially a problem in PDEs when the original evolutionary system is a distributed parameter system: can a priori estimates of $\|\cdot\|_F$ be obtained in terms of norms in spaces which are both intrinsic to the given problem and readily identifiable?”

For a detailed discussion of HUM, we can refer to [11]. Through this adjoint problem, one may connect both controllability problems and minimization problems of appropriate functionals. The existence of solutions to these minimization problems is in turn related to certain inequalities, the so-called observability inequalities, for the dynamical system in question, which show that certain observed quantities of the solution uniquely determine the solution of the dynamical system. The observability inequalities are related to continuous dependence questions of the solution on the initial or the final data. In order to get the observation estimates of the adjoint problem, we can use the multiplier method [3] and microlocal analysis.

In a number of applications, the systems in question are subject to stochastic fluctuations arising as a result of either
uncertain forcing (stochastic external forcing) or uncertainty of the governing laws of the system. Noise due to experimental uncertainties, intrinsic randomness of the media, and so forth plays an important role in wave propagation, thus calling for the inclusion of stochastic terms in the wave equations. When a physical state is modeled, external random noise can be a serious disturbance. Apparently this affects controllability of the model. In this paper we discuss controllability of a vector wave equation with random noise. The wave equation with the dissipative term has been extensively studied by many authors (see [12–14]) and the physical background can be found in many works of literature.

In this paper, we consider the nonlinear stochastic wave equation

\[ H_t = \Delta H + W(H, H_t, \nabla H) + (F + f H) \frac{dB}{dt} + U \quad \text{in } Q_T, \]
\[ \nabla \cdot H = 0 \quad \text{in } Q_T, \]
\[ (H(0), H_t(0)) = \xi_0 \quad \text{in } G, \]
\[ H \times n = 0 \quad \text{in } S_T, \]

(1)

where \( H(\cdot, \cdot, \cdot), U(\cdot, \cdot, \cdot), F(\cdot, \cdot, \cdot) : [0, T] \times G \times \Omega \rightarrow \mathbb{R}^3 \) are 3D stochastic processes, \( W(\cdot, \cdot, \cdot) : \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^9 \rightarrow \mathbb{R}^3 \) is a map which meets some conditions, \( f(\cdot, \cdot, \cdot) : [0, T] \times G \times \Omega \rightarrow \mathbb{R}^3 \) is 1D stochastic process, \( \nabla \) is the gradient operator and \( \nabla H = (\nabla H_1, \nabla H_2, \nabla H_3) \in \mathbb{R}^3 \), \( \Delta \) is the Laplace operator, and \( \cdot \) is the divergence operator; \( Q_T, G, S_T, \Omega \) will be defined in Section 2.

System (1) can be derived from the Maxwell system. Indeed, let us consider the classical Maxwell system

\[ E_t - \nabla \times H = 0, \]
\[ H_t + \nabla \times E = 0, \]

(2)

where \( \nabla \times \) is the curl operator. Differentiating the second equation in (2) with respect to \( t \), it follows that

\[ H_t + \nabla \times E_t = 0. \]

(3)

Combining this with the first equation in (2), we can obtain

\[ H_{tt} + \nabla \times [\nabla \times H] = 0. \]

(4)

Noting the identical equation,

\[ \nabla \times [\nabla \times H] = \nabla (\nabla \cdot H) - \Delta H \]

and \( \nabla \cdot H = 0 \), (4) becomes

\[ H_{tt} - \Delta H = 0. \]

(5)

This motivates us to consider (1). This idea can also be found in [5, 6]. For convenience, we write (1) in the following equivalent form:

\[
\begin{align*}
H_{tt} &= -\nabla \times [\nabla \times H] + W(H, H_t, \nabla H) + (F + f H) \frac{dB}{dt} + U \quad \text{in } Q_T, \\
\nabla \cdot H &= 0 \quad \text{in } Q_T, \\
(H(0), H_t(0)) &= \xi_0 \quad \text{in } G, \\
H \times n &= 0 \quad \text{in } S_T.
\end{align*}
\]

(7)

**Question.** Given an initial condition \( \xi_0 \in L^2(\Omega, \mathcal{F}_0, X) \) (where \( X \) is an appropriately chosen Hilbert space) and a final state \( \xi_1 \in L^2(\Omega, \mathcal{F}_T, X) \), can we find an adapted control \( U \) such that the system (1) is driven \( \varepsilon \)-close to the final condition \( \xi_1 \) in the chosen time period?

Theorem 4 is a positive answer to the above question.

For deterministic wave equations, the exact controllability has been extensively investigated for the past few decades (see [11]). References [9, 15] have studied the stochastic wave equations. In this paper, the method we use to deal with our problem is inspired by the idea of these papers.

This paper is organized as follows. In Section 2, we establish the existence and uniqueness theorem for the initial-boundary value problem. In Section 3, the approximate controllability of (1) is stated and proved.

## 2. The Initial-Boundary Value Problem

Throughout this paper, let \( \{B(t)\}_{0 \leq t \leq T} \) be the standard 1D Brownian motions over the stochastic basic (\( \Omega, \mathcal{F}, \{\mathcal{F}_t\}_{0 \leq t \leq T}, P \)), where \( \{\mathcal{F}_t\}_{0 \leq t \leq T} \) is the augmentation of the filtration generated by the Brownian motions \( \{B(t)\}_{0 \leq t \leq T} \) under the probability measure \( P \) (see [5]). \( G \) is always assumed to be a bounded and simply connected domain in \( R^3, \partial G \) is smooth, and \( Q_T = G \times [0, T], S_T = \partial G \times (0, T) \) with \( T > 0 \) and \( n \) is the outward normal vector on \( \partial G \).

Set

\[
\begin{align*}
H(\text{curl}, G) &= \{u(x) \in L^2(G)^3 : \nabla \times u \in L^2(G)^3\}, \\
H_0(\text{curl}, G) &= \{u(x) \in L^2(G)^3 : \nabla \times u \in L^2(G)^3, \\
& \quad \text{and } n \times u = 0 \text{ on } \partial G\}, \\
H(\text{div}, G) &= \{u(x) \in L^2(G)^3 : \nabla \cdot u \in L^2(G)^3\}, \\
H(\text{div} 0, G) &= \{u(x) \in L^2(G)^3 : \nabla \cdot u = 0\}, \\
X &= [H_0(\text{curl}, G) \cap H(\text{div} 0, G)] \times L^2(G)^3, \\
Y &= H_0(\text{curl}, G) \cap H(\text{div} 0, G).
\end{align*}
\]

(8)

The definitions and properties of these spaces can be found in [16, 17]. \((\cdot, \cdot)\) stands for the inner product in \( L^2(G)^3 \).
Definition 1. A stochastic process \( H \) is said to be a solution of (1) if
\[
(\mathcal{H}(t), \mathcal{H}_t(t)) \in \mathcal{L}^2((\Omega;C([0,T],X))
\]
for each \( t \in [0,T] \),
\[
(\mathcal{H}(0), \mathcal{H}_t(0)) = \xi_0 = (\xi_0^1, \xi_0^2);
\]
(9)
\[
(\mathcal{H}_t(t), \Phi) = (\mathcal{H}_t(0), \Phi) + \int_0^t (\nabla \times \mathcal{H}, \nabla \times \Phi) \, ds
\]
\[
+ \int_0^t (W(\mathcal{H},\mathcal{H}_t,\nabla \mathcal{H}), U) \, ds
\]
\[
+ \int_0^t (F + fH, \Phi) \, dB
\]
holds for all \( t \in [0,T] \) and all \( \Phi \in \mathcal{Y} \), for a.s. \( \omega \in \Omega \).

First, we consider the following system:
\[
\mathcal{H}_t = -\nabla \times [\nabla \times \mathcal{H}] + J + F \frac{dB}{dt} \quad \text{in } \Omega_T,
\]
\(
\nabla \cdot \mathcal{H} = 0 \quad \text{in } \Omega_T,
\)
\[
(\mathcal{H}(0), \mathcal{H}_t(0)) = \xi_0 \quad \text{in } G,
\]
\[
\mathcal{H} \times n = 0 \quad \text{in } \Sigma_T.
\]
(10)

By using the Galerkin method in [15], we can obtain the following theorem.

Theorem 2. Let \( 0 < T < +\infty \), let \( F \) and \( J \) be \( \mathcal{L}^2(G) \)-valued predictable processes, and let \( F, J \in \mathcal{L}^2(\Omega;\mathcal{L}^2(\mathcal{Q}_T)) \), \( \xi_0 = (\xi_0^1, \xi_0^2) \in \mathcal{L}^2(\Omega, \mathcal{F}_0; X) \). There is a solution to the system (10). Furthermore, the solution is pathwise unique and
\[
E \left[ \sup_{0 \leq s \leq T} \left( \|H_t(s)\|^2_{L^2(\mathcal{G})}, \|\nabla \times H(s)\|^2_{L^2(\mathcal{G})} \right) \right]
\]
\[
\leq CE \left[ \left| H_t(0) \right|^2_{L^2(\mathcal{G})}, \|\nabla \times H(0)\|^2_{L^2(\mathcal{G})} \right]
\]
\[
+ CE \int_0^t \left( \int_0^t \|J(s)\|^2_{L^2(\mathcal{G})} ds \right) + CE \int_0^t \|f(s)\|^2_{L^2(\mathcal{G})} ds,
\]
(11)
for every \( t \in [0,T] \).

Next, we consider the system (1).

Theorem 3. Assume the following conditions:

(i) \( F \) is an \( \mathcal{L}^2(\mathcal{G}) \)-valued predictable process and \( F \in \mathcal{L}^2(\Omega;\mathcal{L}^2(\mathcal{Q}_T)) \);

(ii) \( F \) is an \( \mathcal{L}^\infty(\mathcal{G}) \)-valued predictable process and for some nonnegative constant \( b : |f(t,x,\omega)| \leq b \), for all \( (t,x) \in [0,T] \times G \), for a.s. \( \omega \in \Omega \);

(iii) \( \xi_0 \in \mathcal{L}^2(\Omega, \mathcal{F}_0; X) \);

(iv) \( W : \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3 \rightarrow \mathbb{R}^3 \) satisfies
\[
|W (x_1, y_1, z_1) - W (x_2, y_2, z_2)|
\]
\[
\leq L \left| |x_1 - x_2| + |y_1 - y_2| + |z_1 - z_2| \right|,
\]
(12)
for all \( (x_1, y_1, z_1) \in \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3, i = 1, 2 \), where \( |\cdot| : \mathbb{R}^3 \rightarrow \mathbb{R}^3 \) is the Euclidian norm and \( L \) is a positive constant;

(v) \( U \) is an \( \mathcal{L}^2(G) \)-valued predictable process and \( U \in \mathcal{L}^2(\Omega;\mathcal{L}^2(\mathcal{Q}_T)) \).

Then there is a solution to problem (1). Furthermore, the solution is pathwise unique.

Proof. We formally write \( (\mathcal{H}_0(t), \mathcal{H}_t(t)) = \xi_0 = (\xi_0^1, \xi_0^2) \in \mathcal{L}^2(\Omega, \mathcal{F}_0; X) \) for all \( t \in [0,T] \).

Let \( \mathcal{H}^{m}(m = 1, 2 \ldots) \) be the solution of the following linear problem:
\[
\mathcal{H}_t = -\nabla \times [\nabla \times \mathcal{H}] + U + W (\mathcal{H}^{m-1}, \mathcal{H}_t^{m-1}, \nabla \mathcal{H}^{m-1})
\]
\[
+ (F + f \mathcal{H}^{m-1}) \frac{dB}{dt} \quad \text{in } \Omega_T,
\]
\[
\nabla \cdot \mathcal{H} = 0 \quad \text{in } \Omega_T,
\]
\[
(\mathcal{H}(0), \mathcal{H}_t(0)) = \xi_0 \quad \text{in } G,
\]
\[
\mathcal{H} \times n = 0 \quad \text{in } \Sigma_T.
\]
(13)

Since \( \xi_0 \) is \( X \)-valued \( \mathcal{F}_0 \)-measurable, \( W(\xi_0^1, \xi_0^2, \nabla \xi_0^2) \) is independent of time and \( \mathcal{L}^2(\mathcal{Q}_T) \)-valued \( \mathcal{F}_0 \)-measurable by (12). Also, \( F + f \xi_0^2 \) is \( \mathcal{L}^2(G) \)-valued \( \mathcal{F}_0 \)-measurable, and
\[
\left\| F + f \xi_0^2 \right\|_{L^2(\mathcal{Q}_T)} \leq \left\| F \right\|_{L^2(\mathcal{Q}_T)} + b|T|^{1/2} \| \xi_0 \|_{L^2(\mathcal{Q}_T)}.
\]
(14)

If \( \mathcal{H}^{m-1}, \mathcal{H}_t^{m-1} \in \mathcal{L}^2(\Omega;C([0,T];X)) \) is adapted to \( \{F_t\}, W(\mathcal{H}^{m-1}, \mathcal{H}_t^{m-1}, \nabla \mathcal{H}^{m-1}) \) is an \( \mathcal{L}^2(G) \)-valued predictable process and
\[
\left\| F + f \mathcal{H}^{m-1} \right\|_{L^2(\mathcal{Q}_T)} \leq \left\| F \right\|_{L^2(\mathcal{Q}_T)} + b|T|^{1/2} \| \mathcal{H}^{m-1} \|_{L^2(\mathcal{Q}_T)}.
\]
(15)

Therefore, we apply Theorem 2 to problem (13) for \( m = 1, 2 \ldots \).
By virtue of (12), we have
\[
\| W (H^m, H_t^m, \nabla H^m) - W (H^{m-1}, H_t^{m-1}, \nabla H^{m-1}) \|_{L^2(\Omega)}^2 \\
\leq C \left( \left\| H^m - H^{m-1} \right\|_{L^2(\Omega)}^2 + \left\| H_t^m - H_t^{m-1} \right\|_{L^2(\Omega)}^2 \\
+ \left\| \nabla H^m - \nabla H^{m-1} \right\|_{L^2(\Omega)}^2 \right)
\]
\[
\leq C \left( \left\| H^m - H^{m-1} \right\|_{L^2(\Omega)}^2 + \left\| H_t^m - H_t^{m-1} \right\|_{L^2(\Omega)}^2 \\
+ \| H^m - H^{m-1} \|_{H^2(\Omega)}^2 \right)
\]
\[
\leq C \left( \left\| H^m - H^{m-1} \right\|_{L^2(\Omega)}^2 + \left\| H_t^m - H_t^{m-1} \right\|_{L^2(\Omega)}^2 \\
+ \left\| \nabla \times H^m - \nabla \times H^{m-1} \right\|_{L^2(\Omega)}^2 \right)
\]
\[
\leq C \left( \left\| H^m - H^{m-1} \right\|_{L^2(\Omega)}^2 + \left\| H_t^m - H_t^{m-1} \right\|_{L^2(\Omega)}^2 \\
+ \left\| \nabla \times H^m - \nabla \times H^{m-1} \right\|_{L^2(\Omega)}^2 \right)
\]
for every \( t \in [0, T] \). In the last step, we have used the fact that
\[
\| u \|_{H^1(\Omega)} \leq C \| \nabla u \|_{L^2(\Omega)}
\]
for every \( u \in Y \).

Let
\[
Q_m (t) = E \left[ \sup_{0 \leq s \leq t} \left\| (H_t^{m+1} - H_t^m) (s) \right\|_{L^2(\Omega)}^2 + \left\| \nabla \times H^{m+1} (s) - \nabla \times H^m (s) \right\|_{L^2(\Omega)}^2 \right],
\]
for every \( t \in [0, T] \) and each \( m = 1, 2 \ldots \).

Then we can derive that, for some positive constant \( C \),
\[
Q_m (t) \leq C \int_0^t Q_{m-1} (s) \, ds,
\]
for all \( t \in [0, T] \) and all \( m \geq 1 \).

By (11) and (14) we can obtain some positive constant \( K > 0 \) such that
\[
Q_0 (t) \leq K, \quad \forall t \in [0, T].
\]

By induction, it follows that
\[
Q_m (t) \leq \frac{K C^m m^m}{m} \quad \forall t \in [0, T];
\]
then
\[
\sum_{k=1}^m \sqrt{Q_k} (T) < +\infty.
\]

Consequently, \( \{(H^m, H_t^m)\} \) is a Cauchy sequence in \( L^2 (\Omega, C([0, T]; X)) \).

Then
\[
(H (t), H_t (t)) \text{ is } X \text{-valued and } \mathcal{T}_t \text{-measurable}
\]
for each \( t \in [0, T] \),
\[
(H (0), H_t (0)) = \xi_0 = (\xi_0^1, \xi_0^2),
\]
\[
(H^m, H_t^m) \longrightarrow (H, H_t) \text{ in } L^2 (\Omega, C([0, T]; X)).
\]
namely, as \( m \to \infty \),
\[
E \sup_{0 \leq t \leq T} \| (H^m, H'^m) - (H, H_1) \|^2_X \to 0. 
\] (27)

From (13), we can get that, for every \( m \geq 1 \),
\[
(H_t^m (t), \Phi) = (H_t^m (0), \Phi) - \int_0^t \left( (\nabla \times H^m, \nabla \times \Phi) + U, \Phi \right) ds \\
+ \int_0^t \left( W \left( H^{m-1}, H'_t, \nabla H^{m-1} \right) + U, \Phi \right) ds \\
+ \int_0^t (F + f H^{m-1}, \Phi) dB 
\] (28)
holds for every \( t \in [0, T] \), every \( \Phi \in Y \), and a.s. \( \omega \in \Omega \).

By the diagonal process and taking limits, we get that
\[
(H_t (t), \Phi) = (H_t (0), \Phi) - \int_0^t \left( (\nabla \times H, \nabla \times \Phi) + U, \Phi \right) ds \\
+ \int_0^t \left( W \left( H, H_t, \nabla H \right) + U, \Phi \right) ds \\
+ \int_0^t (F, \Phi) dB 
\] (29)
holds for every \( t \in [0, T] \), every \( \Phi \in Y \), and a.s. \( \omega \in \Omega \).

In the end, we prove the uniqueness of the solution.

Let \( H_1 \) and \( H_2 \) be two solutions. We define \( W_i = W(H_i, H_i, \nabla H_i) \) and \( f_i = f H_i \) for \( i = 1, 2 \).

Let \( \Phi \) be the solution of the following linear problem:
\[
H_t = -\nabla \times [\nabla \times H] + W_i (F + f_i) dB/dt + U \quad \text{in} \ T, \\
\nabla \cdot H = 0 \quad \text{in} \ T, \\
(H(0), H_t (0)) = \xi_0 \quad \text{in} \ G, \\
H \times n = 0 \quad \text{in} \ S_T. 
\] (30)

By virtue of (11), we see that, for all \( t \in [0, T] \), \( \Phi_1 - \Phi_2 \) satisfies
\[
E \left[ \sup_{0 \leq s \leq T} \left( \left( \Phi_1 - \Phi_2 \right)_t (\cdot, s) \right)_t^2_{L^2(G)^3} \\
+ \left( \left( \nabla \times \Phi_1 - \nabla \times \Phi_2 \right) (\cdot, s) \right)_t^2_{L^2(G)^3} \right] 
\] (31)
\[
\leq CE \int_0^T \left( \| W_1 (\cdot, s) - W_2 (\cdot, s) \|^2_{L^2(G)^3} ds \\
+ E \int_0^T \| f_1 (\cdot, s) - f_2 (\cdot, s) \|^2_{L^2(G)^3} ds \right). 
\]

3. Approximate Controllability of (1)

Now, we can answer the question in Section 1.

Theorem 4. Suppose that assumptions (i)-(iv) of Theorem 3 hold and \( \xi_1 \in L^2(\Omega, \mathcal{F}_T; X) \) is given. For each \( \epsilon > 0 \), there is a control \( U \) that satisfies the following: \( U(t) \) is an \( L^2(G)^3 \)-valued predictable process over \( \{\Omega, \mathcal{F}, \mathcal{F}_T, P\} \), \( U \in L^2(\Omega, \mathcal{F}_T; L^2(Q_T)^3) \) and
\[
E \left( \left( (H(T), H_t (T)) - \xi_1 \right)_t^2_X \right) < \epsilon, 
\] (33)
where \( H \) is the solution of (1).

In the first part we derive fundamental estimates. The proof of Theorem 4 is given in the second part.

By using the method similar to that in [9, 15], we can establish the following lemmas.

Lemma 5. Let \( V \) be the solution of the system
\[
V_t + \nabla \times [\nabla \times V] = 0 \quad \text{in} \ (T - \tau, T) \times G, \\
\nabla \cdot V = 0 \quad \text{in} \ (T - \tau, T) \times G, \\
V \times n = 0 \quad \text{on} \ [T - \tau, T] \times \partial G, \\
(V(T), V_t (T)) = \alpha \in X 
\] (34)
such that \( (V, V_t) \in C([T - \tau, T]; X) \). Then it holds that
\[
\| \alpha \|^2_X \leq C \int_{T - \tau}^T \| V_t (t) \|^2_{L^2(G)^3} dt, 
\] (35)
for every \( 0 < \tau \leq \min(1, T) \), where \( C \) is a positive constant depending only on \( G \).

Lemma 6. Let \( L \) be the solution of the system
\[
L_t + \nabla \times [\nabla \times L] = V_t \quad \text{in} \ (T - \tau, T) \times G, \\
\nabla \cdot L = 0 \quad \text{in} \ (T - \tau, T) \times G, \\
L \times n = 0 \quad \text{on} \ [T - \tau, T] \times \partial G, \\
(L(T - \tau), L_t (T - \tau)) = 0 \quad \text{in} \ G, 
\] (36)
where \( V \) is the solution of the system (34). Let \( \beta = (L(T), L\tau(T)) \in X \). Then it holds that
\[
\int_{T-\tau}^T \int_G |V_t|^2 \, dx \, dt \leq \|\alpha\|_X \|\beta\|_X, \tag{37}
\]
where \( C \) is a positive constant depending only on \( G \) and \( 0 < \tau \leq \min(1, T) \).

Remark 7. The estimates (35) and (37) naturally carry over to the case where \( \alpha \) is an \( X \)-valued random variable.

If \( \alpha \in L^2(\Omega, \mathcal{F}_{T-\tau}; X) \), then \((V, V_t) \in L^2(\Omega, \mathcal{F}_{T-\tau}; C([T-\tau, T]; X)) \) and
\[
E\left(\|\alpha\|_X^2\right) \leq \frac{C}{T} E\left(\int_{T-\tau}^T \|V_t(t)\|_{L^2(G)}^2 \, dt\right). \tag{38}
\]
Also, \( E\left(\int_{T-\tau}^T \|V_t(t)\|_{L^2(G)}^2 \, dt\right) \leq E(\|\alpha\|_X \|\beta\|_X) \).

**Lemma 8.** Consider the following initial-boundary value problem:
\[
\begin{align*}
  u_t + \nabla \times [\nabla \times u] &= F + fu \frac{dB}{dt} \quad \text{in } (T-\tau, T) \times G, \\
  \nabla \cdot u &= 0 \quad \text{in } (T-\tau, T) \times G, \\
  u \times n &= 0 \quad \text{in } [T-\tau, T] \times \partial G, \\
  (u(T-\tau), u_t(T-\tau)) &= 0 \quad \text{in } G.
\end{align*}
\]
Let \( F \in L^2(\Omega, \mathcal{F}_{T-\tau}; L^2((T-\tau, T) \times G)) \) be given and let \( f \) satisfy (ii) of Lemma 6. Then there is a unique solution \( u \in C((T-\tau, T); X) \) and, for almost all \( \omega \in \Omega \), \((u(\omega), u_t(\omega)) \in C([T-\tau, T]; X) \). Furthermore, it holds that
\[
E\left(\sup_{T-\tau \leq t \leq T} \left\|u(t), u_t(t)\right\|_X^2\right) \leq C_T E\left(\int_{T-\tau}^T \int_{G} \left\|F\right\|_{L^2(G)}^2 \, dx \, dt\right), \tag{40}
\]
for every \( 0 < \tau \leq \min(1, T) \), where \( C \) is a positive constant independent of \( F \) and \( \tau \).

Let \( \alpha \in L^2(\Omega, \mathcal{F}_{T-\tau}; X) \) be given and let \( V, U, \) and \( L \) be the solutions of (34), (39), and (36), respectively. Set \( F = V_t \) in (39). We will estimate \( u(T-\tau) - L(T-\tau) \).

**Lemma 9.** Assume that \( 0 < \tau \leq \min(1, T) \). Set \( z = u - L \). Let \( M \) be a positive constant such that \( E(\|\alpha\|_X(L(T), L_t(T))\|_X^2) \leq M^2 \). Then it holds that
\[
E\left(\left\|(z(T), z_t(T))\right\|_X^2\right) \leq C_T M^2, \tag{41}
\]
where \( C \) is a positive constant independent of \( \tau \).

Consider the map
\[
\Lambda : L^2(\Omega, \mathcal{F}_{T-\tau}; X) \rightarrow L^2(\Omega, \mathcal{F}_{T-\tau}; X),
\]
\[
\alpha \mapsto V 
\rightarrow V_t 
\rightarrow L \rightarrow (L(T), L_t(T)) = \Lambda(\alpha) = \beta.
\]
\[
\tag{42}
\]
The following property of \( \Lambda \) is essential for Theorem 4.

**Lemma 10.** For every \( \mathcal{F}_{T-\tau} \)-measurable random variable \( \xi \) with values in \( X \), there exists an \( \alpha^* \in L^2(\Omega, \mathcal{F}_{T-\tau}; X) \) such that
\[
\Lambda(\alpha^*) = \xi. \tag{43}
\]
In fact, Lemma 10 can be obtained from Lemmas 5 and 6 and Lax-Milgram lemma.

The major technical result, essential in our work, is a generalization of the Martingale representation theorem (see [18]) that is summarized in the following lemma from [9, 15].

**Lemma 11.** Given an \( \mathcal{F}_T \)-measurable random variable \( \xi \), for any \( \epsilon > 0 \), there exist \( \tau > 0 \) and an \( \mathcal{F}_{T-\tau} \)-measurable random variable \( \xi_\epsilon \) such that, for some \( \epsilon = \epsilon(\tau) > 0 \), \( E(\|\xi - \xi_\epsilon\|_X^2) < \epsilon \) and \( E(\|\xi_\epsilon\|_X^2) \leq E(\|\xi\|_X^2) \).

**Remark 12.** The proof of Lemma 11 is similar to [15, Lemma 1.2] and [9, Lemma 1].

Now, we can prove our main result.

**Proof of Theorem 4.** The following procedure shows the construction of the approximate control. We use the Hilbert uniqueness method.

(1) Choose an \( \epsilon > 0 \) and a desired final state \( \xi_1 \) for the system (1).

(2) Solve the forward uncontrolled system
\[
\begin{align*}
  u_t + \nabla \times [\nabla \times u] &= (F + fu) \frac{dB}{dt} \quad \text{in } Q_T, \\
  \nabla \cdot u &= 0 \quad \text{in } Q_T, \\
  u \times n &= 0 \quad \text{on } S_T, \\
  (u(0), u_t(0)) &= \xi_0 \quad \text{in } G.
\end{align*}
\]
and find the solution \( u(t); \) set \( \xi_2 = (u(T), u_t(T)) \in L^2(\Omega, \mathcal{F}_T; X) \). This is an \( \mathcal{F}_T \)-measurable random variable.

(3) Find the distance of the uncontrolled solution \( \xi_2 \) from the desired state \( \xi_1 \) and set \( \xi = \xi_1 - \xi_2 \). This is an \( \mathcal{F}_T \)-measurable random variable.

(4) According to Lemma 11, we can approximate \( \xi \) by \( \mathcal{F}_{T-\tau} \)-measurable random variable \( \xi_\epsilon \) such that
\[
E(\|\xi - \xi_\epsilon\|_X^2) < \frac{\epsilon}{4}, \tag{45}
\]
\[
E(\|\xi_\epsilon\|_X^2) \leq E(\|\xi\|_X^2). \tag{46}
\]
We can take \( \tau \) small sufficiently such that
\[
0 < \tau < \min(1, T), \tag{47}
\]
\[
C_T M^2 < \frac{\epsilon}{4}, \tag{48}
\]
where \( C \) is the same as in (41) and \( M^2 = E(\|\xi\|_X^2) \).
From Lemma 10, we can find the solution $\alpha^*$ of the equation $\Lambda(\alpha) = \xi_\alpha$.

Find the solution $V^*$ of (34) with $\alpha = \alpha^*$.

According to Lemma 8, we can obtain the solution $u^*$ of (39) with $F = V^*$.

Extend $u^*$ to $[0, T - \tau]$ such that $u^* = 0$ for $t \in [0, T - \tau]$. Then $(u^*, u_t^*) \in L^2(\Omega, F_{\omega_T}; C([0, T]; X))$ and $(u^*, u_t^*)$ is $F_{\omega_T}$-measurable for each $t \in [0, T]$. Furthermore, $u^*$ is a pathwise unique solution of the following problem:

$$u_{tt}^* + \nabla \times [\nabla \times u^*] = V^*_t \chi_{[T-\tau, T]} + f u^* \frac{dB}{dt} \quad \text{in } Q_T,$$

$$\nabla \cdot u^* = 0 \quad \text{in } Q_T,$$

$$u^* \times n = 0 \quad \text{in } S_T,$$

$$(u^*(0), u_t^*(0)) = 0 \quad \text{in } G,$$

where $\chi_{[T-\tau, T]}$ is the characteristic function of the time interval $(T - \tau, T]$.

Define $U = V^*_t \chi_{[T-\tau, T]} - W(u + u^*, u_t + u_t^*, \nabla u + \nabla u^*)$, where $w$ is the solution of (44).

Now we verify that $U$ is indeed a desired control for system (1). It is obvious that $U$ is an $L^2(G)^3$-valued predictable process over $\Omega, F, F_{\omega_T}, P$ and $U \in L^2(\Omega, F_{\omega_T}; L^2(Q_T))$. We set $H = u + u^*$. Then $H$ is a solution of (1). Furthermore, $$(H(T), H_t(T)) = \xi_2 + (L^* (T), L_t^* (T)) + (z^* (T), z_t^* (T)),$$

where $L^*$ is the solution of (36) with $V_t^*$ being replaced by $V^*_t$ such that $(L^* (T), L_t^* (T)) = \xi_\alpha$, and $z^* = u^* - L^*$. Hence, by virtue of (41), (45)–(48), we have

$$E \left( \| (H(T), H_t(T)) - \xi_1 \|^2_X \right)$$

$$= E \left( \| \xi_2 - \xi_1 + (L^* (T), L_t^* (T)) + (z^* (T), z_t^* (T)) \|^2_X \right)$$

$$= E \left( \| \xi_\alpha - \xi + (z^* (T), z_t^* (T)) \|^2_X \right)$$

$$\leq 2E \left( \| \xi - \xi_\alpha \|^2_X \right) + 2E \| z^* (T), z_t^* (T) \|^2_X < \epsilon.$$  

This completes the proof of Theorem 4.
