The pricing problem of geometric average Asian option under fractional Brownian motion is studied in this paper. The partial differential equation satisfied by the option’s value is presented on the basis of no-arbitrage principle and fractional formula. Then by solving the partial differential equation, the pricing formula and call-put parity of the geometric average Asian option with dividend payment and transaction costs are obtained. At last, the influences of Hurst index and maturity on option value are discussed by numerical examples.

1. Introduction

Option pricing theory has been an unprecedented development since the classic Black-Scholes option pricing model [1] was proposed. Asian options are a kind of common strong path-dependent options, whose value depends on the average price of the underlying asset during the life of the option. Fusai and Meucci [2] have discretely studied Asian option pricing problem under the Levy process. Vecer [3] has got the unified algorithm of the Asian option value based on the basic theory of stochastic analysis. Večeř and Xu [4] extended the method of removing path correlation to the case in a semimartingale model and obtained the partial differential equation of the option value under the standard Brownian motion.

However, the empirical analysis shows that there is a long-term correlation between the underlying asset prices, so that the geometric Brownian motion is not considered as an ideal tool to describe the process of asset price. Since fractional Brownian motion has the properties of self-similarity, thick tail, and long-term correlation, that fractional Brownian motion has become a good tool to depict the process of underlying asset price. According to the standard Brownian motion, Mandelbrot and Van Ness [5] obtained a stochastic integral form of fractional Brownian motion. Based on the wick product, Duncan et al. [6] introduced fractional Itô integral. Elliott and van der Hoek and others [7] have studied fractional Brownian motion with Hurst parameter belonging to the interval (1/2, 1), and they obtained fractional Girsanov theorem and fractional Itô formula by using wick product.

Because an Itô formula for generalized functionals of a fractional Brownian motion with arbitrary Hurst parameter [8] was obtained by Christian Bender, it brought great convenience to option pricing.

In the reality of the securities market, investors were faced with considerable and nonignorable transaction costs and Leland [8] firstly examined the problems of option pricing and hedging with transaction costs. Due to infinite variation of geometric Brownian motion, transaction costs would become infinite in the continuous time completely hedging strategy. So Leland suggested that no-arbitrage assumption is replaced by Delta hedging strategy under the condition of discrete time occasions and transaction costs. The model was then extended by Hoggard et al. and others [9]. Guasoni [10] studied the standard option with transaction costs under the fractional Brownian motion, but he did not obtain option pricing formula. Then Liu and Chang and others [11] extended the option pricing with transaction costs under fractional Brownian motion and provide an approximate solution of the nonlinear Hoggard-Whalley-Wilmott equation. Wang et al. and others [12–16] have systematically discussed the European option pricing problems with transaction costs and long-range dependence. But these studies are usually aimed at European standard option pricing with transaction costs.
options. To the authors' knowledge, there does not exist systematic research about Asian options under time-varying fractional Brownian motion.

In this paper, Asian option pricing problems with transactions costs and dividends under fractional Brownian motion are studied. Firstly, the partial differential equation satisfied by geometric average Asian option value is obtained on the basis of no-arbitrage principle. Then the analytic expressions of option value and parity formula are presented by solving the partial differential equation. At last, the influences of Hurst exponent and maturity on option value are discussed by numerical examples.

2. Geometric Average Asian Options Pricing Model under Fractional Brownian Motion

**Definition 1** (see [17]). Let \((\Omega, F, P)\) be a complete probability space on which a standard fractional Brownian motion with Hurst exponent \(H (0 < H < 1)\) is continuous, centered Gaussian processes \(\{B_H(t), t \geq 0\}\) with covariance functions \(\text{Cov}(B_H(t), B_H(s)) = (1/2)(|t|^{2H} + |s|^{2H} - |t-s|^{2H}), s, t > 0\).

In 2003, Bender has obtained an Itô formula for generalized functionals of a fractional Brownian motion with arbitrary Hurst parameter [18]. The following lemma is obtained by using the integral Itô formula.

**Lemma 2.** Suppose that stochastic process \(S_t\) satisfied the following equation:

\[
dS_t = \mu S_t dt + \sigma S_t d B_H(t),
\]

where \(\mu\) and \(\sigma\) are, respectively, drift coefficient and diffusion coefficient. Suppose that stochastic process \(f = f(t, J_t, S_t)\); then, for any \(t \in [0, T]\), one has

\[
df = \left( \frac{\partial f}{\partial t} + \mu S_t \frac{\partial f}{\partial S_t} dt + \frac{\partial f}{\partial J_t} dJ_t + H(\sigma S_t)^2 t^{2H-1} \frac{\partial^2 f}{\partial S_t^2} dt \right)
+ \sigma S_t \frac{\partial f}{\partial S_t} d B_H(t),
\]

where \(J_t = \exp(\frac{1}{t} \int_0^t \ln S_u du)\) is geometric average of \(S_t\) between the time period of \([0, t]\).

In this paper, the following basic assumptions were needed.

(i) Underlying asset price, \(S_t\), satisfied the stochastic differential equations

\[
dS_t = (\mu - q_t) S_t dt + \sigma S_t d B_H(t),
\]

where \(\mu\) is the expected return, \(q_t\) denotes dividend yield, \(\sigma\) is volatility, and \(B_H(t)\) is a fractional Brownian motion.

(ii) Risk-free interest rate \(r_t\) is a certain function of time \(t\).

(iii) Transaction costs are proportional to the value of the transaction in the underlying. Let \(k\) denote the transaction cost per unit dollar of transaction, where \(k\) is a constant. To buy or sell \(\gamma_t\) shares of the underlying asset need pay proportional transaction costs \((k|\gamma_t| S_t)\); note that \(\gamma_t > 0\) denotes buying the underlying asset and \(\gamma_t < 0\) denotes selling.

(iv) The expected return of the hedge portfolio equals the risk-free rate \(r_t\).

Let \(V = V(t, J_t, S_t)\) denote the value of the geometric average Asian call at time \(t\), where \(J_t = \exp(\int_0^t \ln S_u du)\) is geometric average of underlying asset in \([0, t]\). Construct a portfolio \(\Pi_t\) long one position of the geometric average Asian call, and sell \(\Delta\) shares of the underlying asset. Then the value of the portfolio at time \(t\) is

\[
\Pi_t = V_t - \Delta S_t.
\]

After the time interval \(\delta t\), the change in the value of the portfolio \(\Pi\) is as follows:

\[
\delta \Pi_t = \delta V_t - \Delta \delta S_t - \Delta t q_t S_t \delta t - \kappa \gamma_t \delta V t_{t+\delta t},
\]

where \(\delta S_t\) denotes the change in the underlying asset \(S_t\) between \([t, t + \delta t]\). Choose \(\Delta_t = \delta V_t/\delta S_t\); then, (5) becomes

\[
\delta \Pi_t = \left( \frac{\partial V}{\partial t} + H \sigma^2 S_t^{2H-1} \frac{\partial^2 V}{\partial S_t^2} dt - \Delta t q_t S_t \right) \delta t + \frac{\partial V}{\partial J_t} \delta J_t - \kappa \gamma_t S_t \delta t,
\]

where

\[
\gamma_t = \Delta_{t+\delta t} - \Delta_t = \frac{\partial V}{\partial S_t} = \frac{\partial \sigma}{\partial S_t} \delta S_t + \frac{\partial \sigma}{\partial J_t} \delta J_t + O(\delta t) \quad \text{(7)}
\]

The mathematical expectation of transaction costs is obtained in the following form:

\[
E(k|\gamma_t| S_t \delta t) = k \left( \frac{\partial^2 V}{\partial S_t^2} \right) S_t E(\delta B_H(t)|S_t \delta t) + O(\delta t) \quad \text{(8)}
\]

\[
= \sqrt{\frac{k \sigma^2}{\pi}} \left| \delta t \right|^H \frac{\partial^2 V}{\partial S_t^2} + O(\delta t).
\]
By assumption (iv), the following relation holds:
\[ E(\delta \Pi_t) = r_t \Pi_t \delta t. \]  
(9)

By (6) and (8), one has
\[ E(\delta \Pi_t) = \left( \frac{\partial V}{\partial t} + H \sigma^2 S^2_t t^{2H-1} \frac{\partial^2 V}{\partial S^2} - \frac{\partial V}{\partial S} q_t S_t \right) \delta t 
+ \frac{\partial V}{\partial J_t} I_t \delta J_t - \sqrt{\frac{2}{\pi}} k \sigma S^2 \frac{\partial V}{\partial S} \right) \delta t + O(\delta t). \]  
(10)

Substituting (10) into (9), the following partial differential equation is obtained:
\[ \frac{\partial V}{\partial t} + H \sigma^2 S^2_t t^{2H-1} \frac{\partial^2 V}{\partial S^2} + (r_t - q_t) S_t \frac{\partial V}{\partial S} + \frac{\partial V}{\partial J_t} I_t \ln(S_t/I_t) 
- \sqrt{\frac{2}{\pi}} k \sigma S^2 \frac{\partial V}{\partial S} \right) r_t V = 0. \]  
(11)

Substituting \( I_t = e^{(1/t) \int_0^t \ln S_{dt}} \) and \( dJ_t/dt = J_t (\ln(S_t/I_t))/t \) into (11), the following equation is obtained:
\[ \frac{\partial V}{\partial t} + H \sigma^2 S^2_t t^{2H-1} \frac{\partial^2 V}{\partial S^2} + (r_t - q_t) S_t \frac{\partial V}{\partial S} + \frac{\partial V}{\partial J_t} I_t \ln(S_t/I_t) 
- \sqrt{\frac{2}{\pi}} k \sigma S^2 \frac{\partial V}{\partial S} \right) r_t V = 0, \]  
(12)

denoting
\[ \tilde{\sigma}^2 = 2\sigma^2 \left( H t^{2H-1} - \sqrt{\frac{2}{\pi}} k \sigma (\delta t)^{H-1} \right). \]  
(13)

Substituting (13) into (12), the following result is obtained.

**Theorem 3.** Suppose that the underlying asset price \( S_t \) satisfies (3); then, the value, \( V(t, I_t, S_t) \), of the geometric average Asian call with strike price \( K \), maturity \( T \), and transaction fee rate \( k \) at time \( t \) is
\[ V(t, I_t, S_t) = \left( \int_0^t e^{r(\theta - \theta')/T - \sigma^2 (\theta' - t)^H (\sigma')^2 / 2T^2} \right)^{1/T} \right) e^{-r(T-t)} \left( \int_{\theta}^{T} \sigma^2 (\theta - t)^H (\sigma')^2 / 2T^2 \right) \frac{N(d_1)}{N(d_2)} + Ke^{-r(T-t)} \left( \int_{\theta}^{T} \sigma^2 (\theta - t)^H (\sigma')^2 / 2T^2 \right) \frac{N(d_2)}{N(d_1)}, \]  
(17)

where
\[ d_1 = \ln(\left( \int_0^t \frac{e^{-r(\theta - \theta')/T - \sigma^2 (\theta' - t)^H (\sigma')^2 / 2T^2}}{K} \right) + r^* (T-t) + \sigma^2 \left( \frac{t^{2H} - t^{2H}}{2} \right)), \]  
\[ d_2 = d_1 - \sigma^2 \frac{T^{2H} - t^{2H}}{2T}, \]  
\[ r^* = \frac{\int_{\theta}^{T} \sigma^2 (\theta - t)^H (\sigma')^2 / 2T^2}{T-t} \]  
\[ \sigma^* = \sigma \left( 1 - \frac{4H (\theta^2 - \theta'^2)}{T(2H + 1)} \right), \]  
\[ N(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-t^2/2} dt. \]  
(18)
Proof. By Theorem 3, the value, \( V(t, J_t, S_t) \), of the geometric average Asian call satisfies the following model:

\[
\frac{\partial V}{\partial t} + \frac{1}{2} \sigma^2 S_t^2 \frac{\partial^2 V}{\partial S_t^2} + \left( r_t - q_t \right) S_t \frac{\partial V}{\partial S_t} + \frac{\partial V}{\partial J_t} \ln \left( \frac{S_t}{J_t} \right) - r_t V = 0,
\]

\( V(T, J_T, S_T) = (J_T - K)^+ \).

Let \( \xi_t = (1/T)[\ln J_t + (T-t) \ln S_t] \), \( V(t, J_t, S_t) = U(t, \xi_t) \); then

\[
\frac{\partial U}{\partial t} = \frac{\ln (J_t/S_t)}{T} \frac{\partial U}{\partial \xi_t} + \frac{\partial U}{\partial S_t} = \frac{T-t}{T} \frac{\partial U}{\partial S_t},
\]

\[
\frac{\partial^2 V}{\partial S_t^2} = \left( \frac{T-t}{T S_t} \right)^2 \frac{\partial^2 U}{\partial S_t^2} + \frac{T-t}{T S_t} \frac{\partial^2 U}{\partial J_t \partial S_t} + \frac{T-t}{T S_t} \frac{\partial^2 U}{\partial J_t \partial \xi_t}.
\]

Combined with the boundary conditions of the call option, \( V(T, J_T, S_T) = (J_T - K)^+ \), the model (19) can be converted to

\[
\frac{\partial U}{\partial t} + \left( r_t - q_t - \frac{\sigma^2}{2} \right) \frac{T-t}{T} \frac{\partial U}{\partial \xi_t} + \frac{\sigma^2}{2} \left( \frac{T-t}{T} \right)^2 \frac{\partial^2 U}{\partial \xi_t^2} - r_t U = 0,
\]

\( U(\xi_T, T) = (e^{\xi_T} - K)^+ \).

Let \( \tau = \gamma(t), \eta_t = \xi_t + \alpha(t) \), \( W(\tau, \eta_t) = U(t, \xi_t) e^{\beta(t)} \) which satisfied the conditions

\[
\alpha(T) = \beta(T) = \gamma(T) = 0,
\]

and then we have

\[
\frac{\partial U}{\partial t} = e^{-\beta(t)} \left( \frac{\partial W}{\partial \tau} \gamma'\left( t \right) - \beta'\left( t \right) W + \frac{\partial W}{\partial \eta_t} \alpha'\left( t \right) \right),
\]

\[
\frac{\partial U}{\partial \eta_t} = e^{-\beta(t)} \frac{\partial W}{\partial \eta_t}, \quad \frac{\partial^2 U}{\partial \eta_t^2} = e^{-\beta(t)} \frac{\partial^2 W}{\partial \eta_t^2}.
\]

Substituting (23) into (21), we can get

\[
y'\left( t \right) \frac{\partial W}{\partial \tau} + \frac{\sigma^2}{2} \left( \frac{T-t}{T} \right)^2 \frac{\partial^2 W}{\partial \eta_t^2} + \left[ \left( r_t - q_t - \frac{\sigma^2}{2} \right) \frac{T-t}{T} + \alpha'\left( t \right) \right] \frac{\partial W}{\partial \eta_t} - \left( r_t + \beta'\left( t \right) \right) W = 0.
\]

Set

\[
\left( r_t - q_t - \frac{\sigma^2}{2} \right) \frac{T-t}{T} + \alpha'\left( t \right) = 0, \quad r_t + \beta'\left( t \right) = 0,
\]

\[
y'\left( t \right) = \frac{\sigma^2}{2} \left( \frac{T-t}{T} \right)^2.
\]

Combining with the terminal conditions \( \alpha(T) = \beta(T) = \gamma(T) = 0 \), we have

\[
\alpha(t) = \int_t^T (r_\theta - q_\theta) \frac{T-\theta}{T} d\theta - \int_t^T \frac{1}{2} \sigma^2 \left( \frac{T-\theta}{T} \right) d\theta = r \ast (T-t),
\]

\[
\beta(t) = \int_t^T r_\phi d\phi,
\]

\[
\gamma(t) = \int_t^T \frac{1}{2} \sigma^2 \left( \frac{T-\theta}{T} \right)^2 d\theta = \frac{\sigma^2}{2} \left( T^{2H} - t^{2H} \right),
\]

where

\[
r^* = \int_t^T (r_\theta - q_\theta) \left( \frac{(T-\theta)T}{T-t} \right) d\theta - \frac{\sigma^2}{2} \left( T^{2H} - t^{2H} \right) + \frac{H \sigma^2 \left( T^{2H+1} - t^{2H+1} \right)}{T (2H+1)} + \frac{1}{2} \text{Le} (H) \sigma^2 \frac{T-t}{T},
\]

\[
\sigma^* = \sigma \left( 1 - \frac{4H \left( T^{2H+1} - t^{2H+1} \right)}{T (2H+1)} \right) \frac{H \left( T^{2H+2} - t^{2H+2} \right)}{T^2 (2H+1) (T^{2H+1} - t^{2H+1})} + \frac{2 \text{Le} (H) \left( T-t \right)^3}{3 \sigma^2 (T^{2H} - t^{2H})} \right)^{1/2}.
\]

Thus the model (21) is converted into the classic heat conduction equation

\[
\frac{\partial W}{\partial \tau} = \frac{\partial^2 W}{\partial \eta_t^2},
\]

\( W(\eta_0, 0) = (e^{\eta_0} - K)^+ \).

Its solution is

\[
W(\eta, \tau) = \frac{1}{2 \sqrt{\pi} \tau} \int_{-\infty}^{\infty} \left( e^{\eta} - K \right)^+ e^{-(\eta - \eta_t)^2/4\tau} d\eta
\]

\[
= \frac{1}{2 \sqrt{\pi} \tau} \int_{\ln K}^{\infty} \left( e^{\eta} - K \right)^+ e^{-(\eta - \eta_t)^2/4\tau} d\eta
\]

\[
= e^{\eta_t + \tau} N \left( \frac{1 + \eta_t - \ln K}{\sqrt{2\tau}} \right) - KN \left( \frac{\eta_t - \ln K}{\sqrt{2\tau}} \right).
\]

After variable reduction, we have

\[
W(\eta, \tau) = \left( \frac{1}{\sqrt{\pi} \tau} \right) e^{-(\eta - \eta_t)^2/2\tau} N \left( d_1 \right)
\]

\[
- KN \left( d_2 \right),
\]

\[
\begin{pmatrix} \xi T + S_t \end{pmatrix} = \left( \frac{1}{\sqrt{\pi} \tau} \right) e^{-(\eta - \eta_t)^2/2\tau} N \left( d_1 \right)
\]

\[
- KN \left( d_2 \right).
\]
where
\[
\frac{2\tau + \eta - \ln K}{\sqrt{2\tau}} = \left( \frac{\left( S_{T-t}^{T-t} \right)^{1/2}}{K} \right) + r^* (T-t) + \sigma^* (t^2H - t^2H) \right) \\
\times \left( \sigma^*(t^2H - t^2H)^{1/2} \right)^{-1} + d_1,
\]
\[
\frac{\eta - \ln K}{\sqrt{2\tau}} = \ln \left[ \frac{\left( S_{T-t}^{T-t} \right)^{1/2}}{K} \right] + r^* (T-t)
\]
\[
\eta^2 - \ln K = \frac{\ln (J_t, S_T - J_t)}{T} = - \left( \frac{J_t, S_T - J_t}{T} \right)^{1/2} e^{r^*(T-t)} - \frac{\sigma^*(T-t)^2}{2} \frac{\bar{W} - \bar{W}|_{t=T}}{d_1} + K e^{-\frac{T-t}{T} N(-d_2)}.
\]

Suppose the underlying asset price satisfies
\[\text{Theorem 7.}
\]

Let \( W(t, J_t, S_t) = U(\xi, t) = W(\eta, t) e^{-\beta(t)} \)
\[
= \left( S_{T-t}^{T-t} \right)^{1/2} e^{r^*(T-t)-\gamma \eta} r^* s(t) (T-t)^{-1/2} \right) \right) N(d_1)
\]
\[
- K e^{-\frac{T-t}{T} \sigma d t} N(d_2).
\]

So the value of geometric average Asian call option at time \( t \) is obtained
\[\text{Theorem 8.}
\]

We let \( \xi_t = (1/T) [t \ln J_t + (T-t) \ln S_t] \); then \( W \) is suitable for the following in \( [\xi_t \in R, 0 \leq t \leq T] \):
\[\text{Proof.}
\]

Taking \( a(T) = 1, b(T) = -K \), the solutions of (38) are
\[\text{The parity formula between call option and put option is}
\]
\[\text{Pricing formula of the geometric average Asian put options can be obtained by Theorems 6 and 7.}
\]

\[\text{Theorem 8.}
\]
Journal of Applied Mathematics

In particular, if \( H = 1/2, k = 0 \), \( r, q, \sigma \) are all constant and price formula (17) is reduced to the following formula [19]:

\[
V(t, J_t, S_t) = \left( J_t S_t^{-1} \right)^{1/T} e^{\left(r^* + \sigma^* (T-t)\right)/T} N\left(d_1\right) - Ke^{-r(T-t)} N\left(d_2\right),
\]

where

\[
d_1 = \frac{\ln \left( \left( J_t S_t^{-1} \right)^{1/T} / K \right) + \left(r^* + \sigma^* \right) (T-t)}{\sigma^* \sqrt{T-t}},
\]

\[
d_2 = d_1 - \sigma^* \sqrt{T-t},
\]

\[
r^* = \left(r - q - \frac{\sigma^*}{2}\right) T - t, \quad \sigma^* = \frac{\sigma \left(T - t\right)}{\sqrt{3T}}.
\]

The following results are consequences of the above theorems.

Corollary 9. If risk-free interest rate \( r \), dividend yield \( q \), and volatility \( \sigma \) are all constant, then the price formulas of geometric average Asian call and put option with strike price \( K \), maturity \( T \), and transaction fee rate \( k \) under fractional Brownian motion at time \( t \) are, respectively,

\[
V_C(t, J_t, S_t) = \left( J_t S_t^{-1} \right)^{1/T} e^{\left(r^* + \sigma^* (T-t)\right)/T} N\left(d_1\right) - Ke^{-r(T-t)} N\left(d_2\right),
\]

\[
V_P(t, J_t, S_t) = -\left( J_t S_t^{-1} \right)^{1/T} e^{\left(r^* + \sigma^* (T-t)\right)/T} N\left(-d_1\right) + Ke^{-r(T-t)} N\left(-d_2\right),
\]

where

\[
r^* = \left(r - q - \frac{\sigma^*}{2}\right) T - t - \frac{\sigma^*}{2} \frac{T^2}{T} - t^2,
\]

\[
\sigma^* = \frac{\sigma \left(T - t\right)}{\sqrt{3T}}.
\]

The rest of symbols are the same as Theorem 6.

Corollary 10. If risk-free interest rate \( r \), and dividend yield \( q \), are the functions of time \( t \) and volatility \( \sigma \) is constant, then the price formula \( V(t, J_t, S_t) \) with respect to geometric average Asian call option with strike price \( K \), maturity \( T \), and transaction fee rate \( k \) under standard Brownian motion at time \( t \) is

\[
V(t, J_t, S_t) = \left( J_t S_t^{-1} \right)^{1/T} e^{\left(r^* + \sigma^* (T-t)\right)/T} \int_t^T r^{\theta dt} N\left(d_1\right) - Ke^{-r(T-t)} N\left(d_2\right),
\]

where

\[
d_1 = \frac{\ln \left( \left( J_t S_t^{-1} \right)^{1/T} / K \right) + \left(r^* + \sigma^* \right) (T-t)}{\sigma^* \sqrt{T-t}},
\]

\[
d_2 = d_1 - \sigma^* \sqrt{T-t},
\]

\[
Le \left( \frac{1}{2} \right) = \sqrt{\frac{2k}{\pi \sigma}} (\delta t)^{-1/2},
\]

\[
r^* = \int_t^T \left((r_\theta - q_\theta) \frac{(T - \theta) \theta}{T} d\theta \right) \left( \frac{\sigma T - t}{T} \right) - \frac{\sigma^* (T-t)}{4T} + \frac{1}{2} Le \left( \frac{1}{2} \right) \sigma^* \frac{\sigma T - t}{T},
\]

\[
\sigma^* = \frac{\sigma (T-t)}{\sqrt{3T}} \left(1 - 2Le \left( \frac{1}{2} \right) \right).
\]

4. Numerical Example

We discuss the impact of Hurst index and transaction rates on the Asian option value by numerical examples. Assume that the parameter selection is as follows:

\[
S_t = 80, \quad t = 0, \quad T = 1, \quad r = 0.05, \quad q = 0.01, \quad \sigma = 0.4,
\]

\[
K = 80, \quad k = 0.003, \quad \delta t = 0.02.
\]

We calculate the value of the option by using the price formula of (45). The relationships between the value of call option or put option and the underlying asset price with different Hurst index are given in Figures 1 and 2, respectively. From Figures 1 and 2, the relationship between Hurst index and Asian option value is negative. Furthermore, the impact on the call option value decreases with the increase of the underlying asset price, but the impact on the put option value decreases with the decrease of the underlying asset price.

By Figures 3 and 4, we can get the change trend of the value of Asian call and put options with the change of maturity and Hurst index at the same time. The option value increases with the maturity increases, but the value of the call option increases faster than the value of a put option increase.

5. Conclusions

Asian options are popular financial derivatives that play an essential role in financial market. Pricing them efficiently and accurately is very important both in theory and practice. We have investigated geometric average Asian option valuation problems with transaction costs under the fractional Brownian motion. By no-arbitrage principle and fractional Itô's formula, this paper has deduced PDE satisfied by the option's value. Meanwhile, the pricing formula and call-put parity of the geometric average Asian option with transaction costs are derived by solving PDE. At last, the influences of Hurst exponent and maturity on option value are discussed through numerical examples.
