We study the numerical solution of Helmholtz equation with Dirichlet boundary condition. Based on the potential theory, the problem can be converted into a boundary integral equation. We propose the mechanical quadrature method (MQM) using specific quadrature rule to deal with weakly singular integrals. Denote by h_m the mesh width of a curved edge Γ_m ($m = 1, \dots, d$) of polygons. Then, the multivariate asymptotic error expansion of MQM accompanied with $O(h_m^3)$ for all mesh widths h_m is obtained. Hence, once discrete equations with coarse meshes are solved in parallel, the higher accuracy order of numerical approximations can be at least $O(h_{\max}^5)$ by splitting extrapolation algorithm (SEA). A numerical example is provided to support our theoretical analysis.

1. Introduction

We consider Helmholtz equation with Dirichlet boundary condition:

$$\Delta u(x) + \alpha^2 u(x) = 0, \quad x \in \Omega, \quad (1)$$

$$u_m(x) = g_m(x), \quad x \in \Gamma_m \left(\Gamma = \bigcup_{m=1}^d \Gamma_m \right),$$

where $\Omega \subset \mathbb{R}^2$ is a polygonal domain with the curved boundary $\Gamma = \bigcup_{m=1}^d \Gamma_m$, $d > 1$, and the angles between Γ_m and Γ_{m+1} are in $(0, 2\pi]$, and the function $g_m(x) = g(x)|_{\Gamma_m}$ is known on Γ_m .

By the potential theory, the solutions of (1) can be represented as a single-layer potential

$$u(y) = \int_{\Gamma} \Phi(y, x) v(x) ds_x, \quad y = (y_1, y_2) \in \Omega, \quad (2)$$

where $x = (x_1, x_2)$ and $\Phi(y, x)$ is the foundation solution of Helmholtz equation, which is given by

$$\Phi(y, x) = \frac{i}{4} H_0^{(1)}(\alpha |x - y|). \quad (3)$$

And $H_0^{(1)} = J_0 + iN_0$ is the Hankel functions of order zero and of the first kind, where

$$J_0(z) = \sum_{n=0}^{\infty} \frac{(-1)^n}{(n!)^2} \left(\frac{z}{2} \right)^{2n} \quad (4)$$

for the Bessel function of order zero and

$$N_0(z) = \frac{2}{\pi} \left(\ln \frac{z}{2} + \gamma \right) J_0(z) + \frac{2}{\pi} \sum_{n=1}^{\infty} \left(\sum_{m=1}^n \frac{1}{m} \right) \frac{(-1)^{n+1}}{(n!)^2} \left(\frac{z}{2} \right)^{2n} \quad (5)$$

for the Neumann function of order zero. And $\gamma = 0.57721 \dots$ is Euler constant.

In what follows, in order to analyze properties of the kernel, we decompose the kernel

$$\Phi(x, y) = k_1(x, y) + k_2(x, y), \quad (6)$$

where $k_1(x, y) = -1/2\pi \ln |x - y|$ is logarithmic singular function and $k_2(x, y) = i/4 - 1/2\pi(\ln(\alpha/2) + \gamma) + O(|x - y| \ln |x - y|)$ is a smooth function. $v(x)$ is the solution of the following equation:

$$g(y) = \int_{\Gamma} \Phi(y, x) v(x) ds_x, \quad y = (y_1, y_2) \in \Gamma. \quad (7)$$

Equation (7) is weakly singular BIE system of the first kind, whose solution exists and is unique as $C_T \neq 1$ [1], where C_T is the logarithmic capacity (i.e., the transfinite diameter). Once $v(x)$ is solved from (7), the function $u(y)$ ($y \in \Omega$) can be calculated by (2).

Galerkin and collocation methods [2, 3] are used to solve (7). However, the discrete matrix is full and each element has to calculate the weakly singular integral for collocation methods or the double weakly singular integral for Galerkin methods, which implies that the work calculating discrete matrix is so large as greatly to exceed to solve the discrete equations. When the numerical methods are applied, the accuracy of numerical solutions is lower at singular points [4] and the corresponding numerical results become unreliable, because the condition numbers are very large.

In the paper, MQM is proposed to calculate weakly singular integrals by Sidi quadrature rules [5], which makes the calculation of the discrete matrix becomes very simple and straightforward without any singular integrals. The convergence theory of approximations is given by estimating eigenvalues of the discrete matrix and using Anselone's collectively compact convergent theory [6], which shows that the method retains the optimal convergence order $O(h_{\max}^3)$ and possesses the optimal condition number $O(h_{\min}^{-1})$. Since MQM possesses the multivariate asymptotic expansion of errors, we can construct SEA to obtain the convergence order $O(h_{\max}^5)$. Once discrete equations on some coarse meshes are solved in parallel, the accuracy of numerical solutions can be greatly improved by SEA.

This paper is organized as follows. Section 2 includes the singularity analysis of the integral kernels and the solution. In Section 3, the MQM is described. In Section 4, we can obtain multiparameter asymptotic expansion of errors and SEA is described. In Section 5, a numerical example is provided to verify the theoretical results.

2. The Integral Kernels and the Solution of Singularity Analysis

Define boundary integral operators on Γ_m :

$$(K_{qm}v_m)(y) = -\frac{1}{2\pi} \int_{\Gamma_m} \Phi(x, y) v_m(x) ds_x, \quad (8)$$

$$y \in \Gamma_q, \quad m, q = 1, \dots, d.$$

Then (7) can be converted into a matrix operator equation

$$KV = G, \quad (9)$$

where $K = [K_{qm}]_{q,m=1}^d$, $V = (v_1(x), \dots, v_d(x))^T$, and $G = (g_1(y), \dots, g_d(y))^T$.

Assume that Γ_m can be described by the parameter mapping:

$$x_m(s) = (x_{1m}(s), x_{2m}(s)) : [0, 1] \longrightarrow \Gamma_m, \quad 0 \leq s \leq 1, \quad (10)$$

with $|x'_m(s)| = [(x'_{1m}(s))^2 + (x'_{2m}(s))^2]^{1/2} > 0$, $m = 1, \dots, d$. Using Sidi periodic transformation [7]

$$\psi_p(\tau) = \frac{\vartheta_p(\tau)}{\vartheta_p(1)} : [0, 1] \longrightarrow [0, 1], \quad p \in N, \quad (11)$$

where $\vartheta_p(\tau) = \int_0^\tau (\sin(\pi\rho))^p d\rho$, then operator (8) is also converted into integral operator on $[0, 1]$:

$$(\bar{B}_{q0}\bar{v}_q)(t) = -\frac{1}{2\pi} \int_0^1 \ln |2e^{-1/2} \sin(\pi(t-\tau))| \bar{v}_q(\tau) d\tau,$$

$$(\bar{B}_{0q}\bar{v}_q)(t) = -\frac{1}{2\pi} \int_0^1 \left(\ln \left| \frac{\bar{x}_q(t) - \bar{x}_q(\tau)}{2e^{-1/2} \sin(\pi(t-\tau))} \right| - \frac{\pi i}{2} + \ln \frac{\alpha}{2} + \gamma \right) \bar{v}_q(\tau) d\tau,$$

$$(\bar{K}_{qm}\bar{v}_m)(t) = \int_0^1 \Phi(\bar{x}_q(t), \bar{x}_m(\tau)) \bar{v}_m(\tau) d\tau, \quad q \neq m, \quad (12)$$

where $\bar{x}_q(t) = x_q(\psi_p(t))$ and $\bar{v}_m(\tau) = v_m(\psi_p(\tau))|x'_m(\psi_p(\tau))| \psi'_p$. Then (9) can be rewritten as

$$(\bar{B}_0 + \bar{B}_1 + \bar{K})\bar{V} = \bar{G}, \quad (13)$$

where $\bar{B}_0 = \text{diag}(\bar{B}_{10}, \dots, \bar{B}_{d0})$, $\bar{B}_1 = \text{diag}(\bar{B}_{01}, \dots, \bar{B}_{0d})$, $\bar{K} = [\bar{K}_{qm}]_{q,m=1}^d$, $\bar{V} = (\bar{v}_1(\tau), \dots, \bar{v}_d(\tau))^T$, $\bar{G} = (\bar{G}_1(t), \dots, \bar{G}_d(t))^T$, and $\bar{G}_m(t) = g_m(\psi_p(t))$.

Let $b_{q0}(t, \tau)$, $b_{0q}(t, \tau)$, and $k_{qm}(t, \tau)$ be the kernels of the integral operators $\bar{B}_{q0}$, $\bar{B}_{0q}$, and $\bar{K}_{qm}$, respectively. Then, the following results hold.

- (1) $b_{q0}(t, \tau)$ is a logarithmic singular function on $t \in [0, 1]$ and $\tau \in [0, 1]$.
- (2) $b_{0q}(t, \tau)$ is a continuous function on $t \in [0, 1]$ and $\tau \in [0, 1]$.
- (3) For $\Gamma_q \cap \Gamma_m = \emptyset$ ($|q - m| \neq 1$ or $d - 1$), $k_{qm}(t, \tau)$ is a continuous function on $t \in [0, 1]$ and $\tau \in [0, 1]$.
- (4) The solution $\bar{v}_q(t)$ is a smooth function under (11).

Lemma 1. If $\Gamma_q \cap \Gamma_m \neq \emptyset$ ($|q - m| = 1$ or $d - 1$) and $p \geq 2$, then $\bar{k}_{qm}(t, \tau) = \sin^p(\pi t) k_{qm}(t, \tau)$ and $(\partial n / \partial t^n) \bar{k}(t, \tau)$ ($n = 1, 2$) are continuous on $[0, 1]^2$.

Proof. Without loss of generality, we assume that the origin $(0, 0) = \Gamma_m \cap \Gamma_q$ of coordinates is a vertex with an interior angle θ_{m+1} . By (6), k_{qm} can be expressed by

$$k_{qm}(t, \tau) = -\frac{1}{2\pi} \ln [a_0^2(t) + a_1(\tau)^2 - 2a_0(t) a_1(\tau) \cos \theta_{m+1}] + k_2(x_q, x_m), \quad (14)$$

where $a_0(t) = |x_q(\psi_p(t))|$ and $a_1(\tau) = |x_m(\psi_p(\tau))|$. We assume that $a_0(0) = a_1(0) = 0$; namely, k_{qm} has the

logarithmic singularity at points $(0, 0)$ and is continuously differentiable in $[0, 1]^2 \setminus (0, 0)$. Consider

$$k_{qm}(t, \tau) = -\frac{1}{2\pi} \ln(a_0^2(t) + a_1(\tau)^2) - \frac{1}{2\pi} \times \ln \left[1 - \frac{2a_0(t) a_1(\tau) \cos \theta_{m+1}}{a_0^2(t) + a_1(\tau)^2} \right] + k_2(x_q, x_m). \quad (15)$$

We have

$$\left| \frac{2a_0(t) a_1(\tau) \cos \theta_{m+1}}{a_0^2(t) + a_1(\tau)^2} \right| \leq |\cos \theta_{m+1}| < 1. \quad (16)$$

So the singularity of $k_{qm}(t, \tau)$ occurs in $(1/2\pi) \ln(a_0^2(t) + a_1(\tau)^2)$. In order to remove the singularity, we define

$$\zeta(t, \tau) = \frac{\sin^p(\pi\tau)}{\psi_p(1)} \ln(a_0^2(t) + a_1(\tau)^2). \quad (17)$$

Since ψ'_p have p order zero, we have the error estimate

$$|\zeta(t, \tau)| = o(\varepsilon^p) |\ln \varepsilon| \rightarrow 0, \quad \text{as } \varepsilon \rightarrow 0, \quad (18)$$

which shows that $\zeta(t, \tau)$ is bounded and continuous on $(C^2[0, 1])^2$ when $\varepsilon/2 \leq t, \tau \leq \varepsilon$ for any $\varepsilon > 0$.

Similarly, we can prove $(\partial/\partial t)\zeta(t, \tau)$ and $(\partial^2/\partial t^2)\zeta(t, \tau)$ are continuous on $(C[0, 1])^2$, which can be obtained by

$$\left| \frac{\partial}{\partial t} \zeta(t, \tau) \right| \leq \left| \frac{\sin^p(\pi\tau)}{\psi_p(1)} \frac{2a_0(t) |x'_{m+1}(\psi_p(t))| |\psi'_p(t)|}{a_0^2(t) + a_1^2(\tau)} \right| \quad (19)$$

$$= O(\varepsilon^p), \quad \forall t, \tau \in \left[\frac{\varepsilon}{2}, \varepsilon \right],$$

and $(\partial^2/\partial t^2)\zeta(t, \tau) = O(\varepsilon^{p-1})$. As above, $(\partial^n/\partial t^n)\zeta(t, \tau)$ ($n = 0, 1, \dots, p$) are continuous on $(C[0, 1])^2$. We can prove that $(\partial^n/\partial t^n)k_{qm}(t, \tau)$ ($n = 0, 1, \dots, p$) are also continuous on $(C[0, 1])^2$. The proof of Lemma 1 is completed. $\square$

3. Mechanical Quadrature Method

Let $h_m = 1/n_m$ ($n_m \in N, m = 1, \dots, d$) be mesh widths and let $t_{mj} = (j-1/2)h_m$ ($j = 1, \dots, n_m$) be nodes. Since an integral operator W is continuous, by the trapezoidal or the midpoint rule [8], we can construct Nyström approximate operator W^h for the integral operator W , defined by

$$(W^h \bar{v}_m)(t) = h_m \sum_{j=1}^{n_m} w(t, t_{mj}) \bar{v}_m(t_{mj}), \quad (20)$$

and the error

$$(W^h \bar{v}_m)(t) - (W \bar{v}_m)(t) = O(h_m^{2l}), \quad l \in N. \quad (21)$$

Since $\bar{B}_{q0}$ has the singularities on $[0, 1]$, by Sidi quadrature formula [5], we get the following approximations $\bar{B}_{q0}^h$ of integral operator $\bar{B}_{q0}$:

$$\begin{aligned} (\bar{B}_{q0}^h \bar{v}_m)(t) &= -\frac{1}{2\pi} h_m \sum_{j=1, t \neq t_{mj}}^{n_m} \ln |2e^{-1/2} \sin \pi(t - t_{mj})| \\ &\times \bar{v}_m(t_{mj}) - \frac{h_m}{2\pi} \ln \left| 2\pi e^{-1/2} \frac{h_m}{(2\pi)} \right| \bar{v}_m(t), \end{aligned} \quad (22)$$

and the error

$$\begin{aligned} &(\bar{B}_{q0}^h \bar{v}_m)(t) - (\bar{B}_{q0} \bar{v}_m)(t) \\ &= -\frac{2}{\pi} \sum_{\mu=1}^{2l-1} \frac{\zeta'(-2\mu)}{(2\mu)!} [\bar{v}_m(t)]^{2\mu} h_m^{2\mu+1} + O(h_m^{2l}), \end{aligned} \quad (23)$$

where $\zeta'(t)$ is the derivative of the Riemann zeta function.

Then, we can get the approximate equation of (13):

$$(\bar{B}_0^h + \bar{B}_1^h + \bar{K}^h) \bar{V}^h = \bar{G}^h, \quad (24)$$

where $\bar{V}^h = (\bar{V}_1^h, \dots, \bar{V}_d^h)$, $\bar{V}_m^h = (\bar{v}_m(t_1), \dots, \bar{v}_m(t_{n_m}))$, $\bar{B}_0^h = \text{diag}(\bar{B}_{10}^h, \dots, \bar{B}_{d0}^h)$, $\bar{B}_{q0}^h = [b_{q0}(t_j, \tau_i)]_{j,i=1}^{n_q}$, $\bar{B}_1^h = \text{diag}(\bar{B}_{01}^h, \dots, \bar{B}_{0d}^h)$, $\bar{B}_{0q}^h = [b_{0q}(t_j, \tau_i)]_{j,i=1}^{n_q}$, $\bar{K}^h = [\bar{K}_{qm}^h]_{q,m=1}^d$, $\bar{K}_{qm}^h = [k_{qm}(t_j, \tau_i)]_{j,i=1}^{n_q n_m}$, $\bar{G}^h = (\bar{G}_1^h, \dots, \bar{G}_d^h)^T$, and $\bar{G}_q^h = (g_q(t_1), \dots, g_q(t_{n_q}))$. Obviously, (24) is a system of linear equations with $n(= \sum_{m=1}^d n_m)$ unknowns. Once $\bar{V}^h$ is solved by (24), the solution $u(y)$ ($y \in \Omega$) can be computed by

$$u^h(y) = \sum_{m=1}^d h_m \sum_{j=1}^{n_m} \Phi(y, x(t_{mj})) \bar{v}_m(t_{mj}). \quad (25)$$

$\bar{B}_{q0}^h$ is symmetric circular matrix and has the form of

$$\begin{aligned} \bar{B}_{q0}^h &= \text{circulate} \left(-\frac{h_m}{2\pi} \ln \left| 2e^{-1/2} \frac{h_m}{\pi} \right|, \dots, \right. \\ &\quad \left. -\frac{h_m}{2\pi} \ln \left| 2e^{-1/2} \sin(\pi(n_m - 1)h_m) \right| \right). \end{aligned} \quad (26)$$

Lemma 2 (see [9]). (1) There exists a positive $c_1 > 0$ so that the eigenvalues λ_β ($\beta = 1, \dots, n_m$) of $\bar{B}_{q0}^h$ satisfy $c_1 > \lambda_\beta > 1/(2\pi n_m)$. (2) The condition number of $\bar{B}_{q0}^h$ is $O(n_m)$. (3) $\bar{B}_{q0}^h$ is invertible, and $(\bar{B}_{q0}^h)^{-1}$ is uniformly bounded with the spectral norm $\|(\bar{B}_{q0}^h)^{-1}\| = O(n_m)$.

Based on Lemma 2, we immediately get the following corollary.

Corollary 3. (1) $\bar{B}_0^h$ is invertible, and $(\bar{B}_0^h)^{-1}$ is uniformly bounded with the spectral norm $\|(\bar{B}_0^h)^{-1}\| = O(n_0)$. (2) The condition number of $\bar{B}_0^h$ is $O(n_0)$, where $n_0 = \max_{m=1}^d n_m$.

From Corollary 3, we know that (24) is equivalent to

$$\left(E^h + (\bar{B}_0^h)^{-1}(\bar{B}_1^h + \bar{K}^h)\right)\bar{V}^h = (\bar{B}_0^h)^{-1}G^h, \quad (27)$$

where E^h denotes the unit matrix.

Now we give the following definitions to discuss the approximate convergence in (27).

Define a subspace $C_0[0, 1] = \{v(t) \in C[0, 1] : v(t)/\sin^2(\pi t) \in C[0, 1]\}$ of the space $C[0, 1]$ with a norm $\|v\|^* = \max_{0 \leq t \leq 1} |v(t)/\sin^2(\pi t)|$. Let $S_m^h \subset C_0[0, 1]$ be a piecewise linear function subspace with base points $\{t_i\}_{i=0}^{n_m-1}$, and let $e_j(t)$ $j = 0, \dots, n_m - 1$ be base function satisfying $e_j(t_i) = \delta_{ji}$. Define a prolongation operator $P^{h_m} : \mathfrak{R}^{n_m} \rightarrow S^{h_m}$ satisfying

$$P^{h_m}\omega = \sum_{j=0}^{n_m-1} \omega_m e_j(t), \quad \forall \omega = (\omega_{m1}, \dots, \omega_{mn_m}) \in \mathfrak{R}^{n_m}. \quad (28)$$

Define a restricted operator $R^{h_m} : C_0[0, 1] \rightarrow \mathfrak{R}^{n_m}$ satisfying

$$R^{h_m}v_m = (v_m(t_{m1}), \dots, v_m(t_{mn_m})) \in \mathfrak{R}^{n_m}, \quad (29)$$

$$\forall v_m \in C_0[0, 1].$$

Replacing $(\bar{B}_0^h)^{-1}(\bar{B}_1^h + \bar{K}^h) = P^h(\bar{B}_0^h)^{-1}R^h(\bar{B}_1^h + \bar{K}^h)$, $\bar{V}^h = P^h\bar{V}^h$, and $\bar{G} = P^h\bar{G}^h$, we construct an operator equation

$$\left(E^h + (\bar{B}_0^h)^{-1}(\bar{B}_1^h + \bar{K}^h)\right)\bar{V}^h = (\bar{B}_0^h)^{-1}\bar{G}^h, \quad (30)$$

where $P^h = \text{diag}(P_1, \dots, P_d)$ and $R^h = \text{diag}(R_1, \dots, R_d)$. Obviously, if $\bar{V}^h$ is the solution of (30), then $R^h\bar{V}^h$ must be the solution of (27); conversely, if $\bar{V}^h$ is the solution of (27), then $P^h\bar{V}^h$ must be the solution of (30). In order to prove the convergence of MQM, we give the following lemma.

Lemma 4 (see [9]). *The operator sequence $\{P_q(\bar{B}_{q0}^h)^{-1}R_q\bar{B}_{q0} : C^2[0, 1] \rightarrow C[0, 1]\}$ is uniformly bounded and convergent to the embedding operator I .*

Corollary 5. *Let the Nyström approximation W^h be defined by (20). (1) For $\Gamma_q \cap \Gamma_m = \emptyset$, one has*

$$P_m(\bar{B}_{m0})^{-1}R_mW^h \xrightarrow{c.c} (\bar{B}_{m0})^{-1}W, \quad \text{in } C[0, 1] \rightarrow C[0, 1]. \quad (31)$$

(2) For $\Gamma_q \cap \Gamma_m \neq \emptyset$, one has

$$P_m(\bar{B}_{m0})^{-1}R_m\bar{K}_{qm}^h \xrightarrow{c.c} (\bar{B}_{m0})^{-1}\bar{K}_{qm}, \quad (32)$$

$$\text{in } C[0, 1] \rightarrow C[0, 1],$$

where $\bar{K}_{qm}^h$ is the Nyström approximation of integral operator $\bar{K}_{qm}$ with the kernel $\bar{k}_{qm}(t, \tau) = \sin^p(\pi t)k_{qm}(t, \tau)$ and $\xrightarrow{c.c}$ denotes the collectively compact convergence.

Theorem 6. *Let $\Gamma = \cup_{m=1}^d \Gamma_m$ with $C_T \neq 1$ and Γ_m ($m = 1, \dots, d$) be smooth curve. The operator sequence $\{P^h(\bar{B}_0^h)^{-1}R^h(\bar{B}_1^h + \bar{K}^h)\}$ is collectively convergent to $(\bar{B}_0)^{-1}(\bar{B}_1 + \bar{K})$ in $V = C_0[0, 1]^d$:*

$$P^h(\bar{B}_0^h)^{-1}R^h(\bar{B}_1^h + \bar{K}^h) \xrightarrow{c.c} (\bar{B}_0)^{-1}(\bar{B}_1 + \bar{K}). \quad (33)$$

Proof. Let $\Theta = \{v : \|v\| \leq 1, v \in V\}$ be a unit ball. $H = \{h^1, h^2, \dots\}$ is the grid step sequence, where $h^n = \{h_1^{(n)}, h_2^{(n)}, \dots, h_d^{(n)}\}$ with $n \rightarrow \infty$, $\max_{1 \leq m \leq d} h_m^{(n)} \rightarrow 0$. We arbitrarily take a sequence $\{Z_h\}_{h \in H}$ in space Θ , where $Z_h = (Z_{h1}, Z_{h2}, \dots, Z_{hd})^T$ with $\|Z_{hm}/\sin^2(\pi t)\|_\infty \leq 1, m = 1, \dots, d$. We firstly consider the first component of $P^h(\bar{B}_0^h)^{-1}R^h(\bar{B}_1^h + \bar{K}^h)Z_h$:

$$\sum_{m=1}^d P_1(\bar{B}_{10}^h)^{-1}R_1(\bar{B}_{01}^h + \bar{K}_{1m}^h)Z_{hm}. \quad (34)$$

For $\Gamma_m \cap \Gamma_1 = \emptyset$, by Corollary 5, $P_1(\bar{B}_{10}^h)^{-1}R_1(\bar{B}_{01}^h + \bar{K}_{1m}^h) \xrightarrow{c.c} \bar{B}_{10}^{-1}(\bar{B}_{01} + \bar{K}_{1m})$ in $C[0, 1]$, and there exists a convergent subsequence in $\{P_1(\bar{B}_{10}^h)^{-1}R_1(\bar{B}_{01}^h + \bar{K}_{1m}^h)Z_{hm}\}$. For $\Gamma_m \cap \Gamma_1 \neq \emptyset$, we have

$$\begin{aligned} & \left\| P_1(\bar{B}_{10}^h)^{-1}R_1\bar{K}_{1m}^h Z_{hm} \right\|_{0,0} \\ &= \left\| P_1(\bar{B}_{10}^h)^{-1}R_1\bar{K}_{1m}^h \left(\frac{Z_{hm}}{\sin^2(\pi t)} \right) \right\|_{0,0} \\ &\leq \left\| P_1(\bar{B}_{10}^h)^{-1}R_1\bar{B}_{10} \right\|_{0,2} \left\| \bar{B}_{10}^{-1}\bar{K}_{1m} \right\|_{2,0} \left\| \frac{Z_{hm}}{\sin^2(\pi t)} \right\|_\infty. \end{aligned} \quad (35)$$

By Lemma 4, there exists a convergent subsequence in $\{P_1(\bar{B}_{10}^h)^{-1}R_1(\bar{B}_{01}^h + \bar{K}_{1m}^h)Z_{hm}\}$. Based on the above two cases it is proved that there exists an infinite subsequence $H^{(1)} \subset H$ such that the first component converges. Similarly, it can be concluded that there exists an infinite subsequence $H^{(d)} \subset H^{(d-1)} \subset \dots \subset H^{(1)} \subset H$ such that $P^h(\bar{B}_0^h)^{-1}R^h(\bar{B}_1^h + \bar{K}^h)Z_h$ converges. Therefore, $P^h(\bar{B}_0^h)^{-1}R^h(\bar{B}_1^h + \bar{K}^h)$ is collectively compact convergent sequence, and $P^h(\bar{B}_0^h)^{-1}R^h(\bar{B}_1^h + \bar{K}^h) \xrightarrow{P} (\bar{B}_0)^{-1}(\bar{B}_1 + \bar{K})$, where $\xrightarrow{P}$ shows the point convergence. We complete the proof. $\square$

For the stability of MQM, we have the following corollary.

Corollary 7. *Let $\Gamma = \cup_{m=1}^d \Gamma_m$ with $C_\Gamma \neq 1$, let Γ_m ($m = 1, \dots, d$) be smooth curve, let $\bar{B}_0^h, \bar{B}_1^h$, and $\bar{K}^h$ be the discrete matrices defined by (20) and (22), respectively, and let λ_i ($i =$*

$1, \dots, n$) be the eigenvalues of discrete matrix $M^h = \bar{B}_0^h + \bar{B}_1^h + \bar{K}^h$. Then, there exists the bound of condition number

$$\text{Cond}(M^h) = \frac{\max_{1 \leq i \leq n} |\lambda_i(M^h)|}{\max_{1 \leq i \leq n} |\lambda_i(M^h)|} = O(h_{\min}^{-1}), \quad (36)$$

where $h_{\min} = \min_{m=1}^d h_m$, $h_m = 1/n_m$, is the mesh step size of a curved edge Γ_m .

4. Multiparameter Asymptotic Expansion of Errors and SEA

In this section, we derive the multivariate asymptotic expansion of solution errors and describe SEA. We first provide the main result.

Theorem 8. Let $\Gamma = \cup_{m=1}^d \Gamma_m$ with $C_\Gamma \neq 1$. There exists a vector function $\Phi = (\phi_1, \dots, \phi_d)^T$ independent of $h = (h_1, \dots, h_d)$ such that the following multiparameter asymptotic expansion holds at nodes:

$$\bar{V}^h - \bar{V} = \text{diag}(h_1^3, \dots, h_d^3) \Phi + o(h_0^3), \quad h_0 = \max_{1 \leq m \leq d} h_m, \quad (37)$$

where $\bar{V}^h \in S^d$, $\bar{V} \in C^3[0, 1]$.

Proof. By (20) and (22), there exists the asymptotic expansion

$$(\bar{G}^h - \bar{G}) = \text{diag}(h_1^3, \dots, h_d^3) P^h R^h \omega + o(h_0^3), \quad (38)$$

where $h = \max_{m=1}^d h_m$ and $\omega = (\omega_1, \dots, \omega)^T$ with $\omega_m = -\zeta'(-2)(G_m(t))''/\pi$.

Using (13), (21), (23), and (24), we obtain

$$\begin{aligned} & (\bar{B}_0^h + \bar{B}_1^h + \bar{K}^h) R^h (\bar{V}^h - \bar{V}) \\ &= \bar{V}^h - P^h (\bar{B}_0^h + \bar{B}_1^h + \bar{K}^h) R^h \bar{V} \\ &= \bar{V}^h - [(\bar{B}_0 + \bar{B}_1 + \bar{K}) R^h \bar{V} \\ &\quad - \text{diag}(h_1^3, \dots, h_d^3) P^h R^h \gamma] + o(h_0^3) \\ &= (\bar{G}^h - \bar{G}) + \text{diag}(h_1^3, \dots, h_d^3) P^h R^h \gamma + o(h_0^3) \\ &= \text{diag}(h_1^3, \dots, h_d^3) P^h R^h \eta + o(h_0^3), \end{aligned} \quad (39)$$

where $\gamma = (\gamma_1, \dots, \gamma_d)^T$ with $\gamma_m = -\zeta'(-2)(x'(t)\psi'(t)v(t))''/\pi$ and $\eta = (\eta_1, \dots, \eta_d)^T$ with $\eta_m = \omega_m + \gamma_m$. From Corollary 3, we can obtain

$$\begin{aligned} & (E + P^h (\bar{B}_0^h)^{-1} R^h (\bar{B}_1^h + \bar{K}^h)) (\bar{V}^h - \bar{V}) \\ &= \text{diag}(h_1^3, \dots, h_d^3) (\bar{B}_0^h)^{-1} P^h R^h \eta + o(h_0^3). \end{aligned} \quad (40)$$

Constructing the auxiliary equation

$$(E + (\bar{B}_0)^{-1} (\bar{B}_1 + \bar{K})) \Phi = (\bar{B}_0)^{-1} \eta \quad (41)$$

and its approximate equation

$$(E + P^h (\bar{B}_0^h)^{-1} R^h (\bar{B}_1^h + \bar{K}^h)) \Phi^h = (\bar{B}_0^h)^{-1} P^h R^h \eta \quad (42)$$

and substituting (42) into (40), we obtain

$$\begin{aligned} & (E + P^h (\bar{B}_0^h)^{-1} R^h (\bar{B}_1^h + \bar{K}^h)) \\ & \times (\bar{V}^h - \bar{V} - \text{diag}(h_1^3, \dots, h_d^3) \Phi^h) = o(h_0^3). \end{aligned} \quad (43)$$

Since $(E + P^h (\bar{B}_0^h)^{-1} R^h (\bar{B}_1^h + \bar{K}^h))$ is uniformly bounded from Theorem 6, we get

$$\bar{V}^h - \bar{V} - \text{diag}(h_1^3, \dots, h_d^3) \Phi^h = o(h_0^3). \quad (44)$$

Replacing Φ^h with Φ , we can complete the proof. $\square$

The multiparameter asymptotic expansion (37) means that SEA can be applied to solve (7); that is, higher order accuracy $o(h_0^3)$ at coarse grid points can be obtained by solving some discrete equations in parallel. The process of SEA is as follows [10].

Step 1. Take $h^{(0)} = (h_1^{(0)}, \dots, h_d^{(0)})$ and $h^{(m)} = (h_1^{(0)}, \dots, h_m^{(0)}/2, \dots, h_d^{(0)})$, and solve (24) under mesh parameters $h^{(m)}$ in parallel to get the numerical solutions $\bar{V}^{h^{(0)}}(t_{mj})$ and $\bar{V}^{h^{(m)}}(t_{mj})$, $m = 1, \dots, d$, $j = 1, \dots, n_m$.

Step 2. Compute $u^{h^{(0)}}(y)$ and $u^{h^{(m)}}(y)$ ($y \in \Omega$), by (25), $\bar{V}^{h^{(0)}}(t_{mj})$, and $\bar{V}^{h^{(m)}}(t_{mj})$.

Step 3. Compute the extrapolation on the coarse grids as follows:

$$u^*(y) = \frac{8}{7} \left[\sum_{m=1}^d u^{h^{(m)}}(y) - \left(d - \frac{7}{8}\right) u^{h^{(0)}}(y) \right]. \quad (45)$$

Step 4. Compute a posteriori error estimate on the coarse grids as follows:

$$\begin{aligned} & \left| u(y) - \frac{1}{d} \sum_{m=1}^d u^{h^{(m)}}(y) \right| \\ & \leq \left| u(y) - \left[\sum_{m=1}^d u^{h^{(m)}}(y) - \left(d - \frac{7}{8}\right) u^{h^{(0)}}(y) \right] \right| \\ & \quad + \left(\frac{8}{7}d - 1 \right) \left| \frac{1}{d} \sum_{m=1}^d u^{h^{(m)}}(y) - u^{h^{(0)}}(y) \right| \\ & \leq \left(\frac{8}{7}d - 1 \right) \left| \frac{1}{d} \sum_{m=1}^d u^{h^{(m)}}(y) - u^{h^{(0)}}(y) \right| + o(h_0^3). \end{aligned} \quad (46)$$

In the actual calculation process, a posteriori error estimate is immediately used to verify the calculation accuracy.

5. Numerical Example

In this section, we carry out a numerical example for the Helmholtz equation by MQM and SEA, in order to verify the error and stability analysis in the previous sections. Let $\text{Re}(e_p)$ be the real part of $e_p = |u^h(P) - u(P)|$ and let $\text{Im}(e_p)$ be the imaginary part of $e_p = |u^h(P) - u(P)|$, where P denotes a point. Post-error and SEA-error denote the a posteriori error and the error after SEA once, respectively.

Example 1. Consider Helmholtz equation with $\alpha = \sqrt{2}$ on a plate domain Ω . We describe the boundary $\Gamma = \cup_m^4 \Gamma_m$ with $\Gamma_1 = \{(x_1, x_2) \mid 0 \leq x_1 \leq 1, x_2 = 0\}$, $\Gamma_2 = \{(x_1, x_2) \mid 0 \leq x_2 \leq 1, x_1 = 1\}$, $\Gamma_3 = \{(x_1, x_2) \mid 0 \leq x_1 \leq 1, x_2 = 1\}$, and $\Gamma_4 = \{(x_1, x_2) \mid 0 \leq x_2 \leq 1, x_1 = 0\}$. Dirichlet boundary conditions corresponding to the analytical solution $e^{i \times (x_1 + x_2)}$ were applied to the boundary. We compute the numerical solution u^h with $P = A(0.5, 0.5)$ and $P = B(0.6, 0.6)$ using $\varphi_3(t)$. The numerical results are listed in Tables 1 and 2. From Table 1, we can know that the convergence rates of u^h are $O(h_{\max}^3)$ for MQM and that the convergence rates of u^h are at least $O(h_{\max}^5)$ for SEA. From Table 2, we can see $\text{Cond}|_{(2^{k+1}, 2^{k+1}, 2^{k+1}, 2^{k+1})} / \text{Cond}|_{(2^k, 2^k, 2^k, 2^k)} \approx 2 (k = 3, 4, 5)$ to indicate Corollary 7. It verifies the stability of convergent theory for MQM. Those results coincide with the theoretical analysis made.

6. Concluding Remarks

To close this paper, let us make a few concluding remarks.

- (1) Evaluation on entries of discrete matrices is very simple and straightforward without any singular integrals by MQM.
- (2) The numerical experiments show that MQM retains the optimal convergence order $O(h_{\max}^3)$ and possesses the optimal condition number $O(h_{\min}^{-1})$ which shows MQM owns the excellent stability. The approximate solutions accuracy order is at least $O(h_{\max}^5)$ after splitting extrapolation once, which is a great improvement in accuracy.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
