*Cornus mas* L. is indigenous to Europe and parts of Asia. Although *Cornus* is widely considered to be an iridoid rich genera, only two iridoids have been previously found in this plant. The lack of information on taxonomically and biologically active iridoids prompted us to develop and optimize an analytical method for characterization of additional phytochemicals in *C. mas* fruit. An ultra performance liquid chromatography (UPLC) coupled with photodiode arrays spectrophotometry (PDA) and electrospray time-of-flight mass spectrometry (ESI-TOF-MS) was employed and mass parameters were optimized. Identification was made by elucidating the mass spectral data and further confirmed by comparing retention times and UV spectra of target peaks with those of reference compounds. Primary DNA damage and antigenotoxicity tests in *E. coli* PQ37 were used to screen the iridoids for biological activity. As a result, ten phytochemicals were identified, including iridoids loganic acid, loganin, sweroside, and cornuside. Nine of these were reported for the first time from *C. mas* fruit. The iridoids did not induce SOS repair of DNA, indicating a lack of genotoxic activity in *E. coli* PQ37. However, loganin, sweroside, and cornuside did reduce the amount of DNA damage caused by 4-nitroquinoline 1-oxide, suggesting potential antigenotoxic activity.

1. Introduction

*Cornus mas* L. is commonly known as European cornelian cherry and belongs to the Cornaceae family. It is a tall deciduous shrub or small tree (3–6 m in height) that is indigenous to Europe and parts of Asia [1, 2]. The fruit is edible but is astringent when unripe. Traditionally, *C. mas* has been used for improving health conditions, such as bowel complaints, fever, and diarrhea [3–6]. Fresh European cornelian cherry fruits are often processed to produce drinks, syrups, and jams [7, 8].

Some investigations of the nutritional and phytochemical properties of European cornelian cherry fruit have been reported previously. The fruit is reported to contain 0.1–0.3% fat, 0.4% protein, 21.7% carbohydrate, 0.8% ash, 0.5% dietary fiber, 6.6–15.1% total sugar (fructose 33.1–43.1%, glucose 53.6–63.1%), and 4.22–9.96% reducing sugars [3, 9]. The fruit has pH 2.7–3.2 and contains at least 15 amino acids, including aspartic acid, glutamic acid, serine, histidine, glycine, threonine, arginine, alanine, tyrosine, valine, phenylalanine, isoleucine, leucine, lysine, and proline [9]. Minerals in *C. mas* fruit include copper (1.2 to 8.1 mg/kg dry weight), iron, zinc, phosphorus, potassium, calcium, magnesium, and sulphur [9]. The vitamin C content of the fruit is reported to be 16.4 to 38.5 mg/100 g [9].

*C. mas* fruit has been found to contain a wide range of phytochemicals, including tannins (131.51–601.2 mg/L), phenolics (29.76–74.83 mg/g dry), organic acids (4.6–7.4%), anthocyanin, fatty acids, and flavonoids [3, 4, 10–16]. Anthocyanins seem to have been a popular subject of previous *C. mas* research. Anthocyanins have been found in the range of 1.12 to 2.92 mg/g in different *C. mas* fruit sources [14, 16, 17]. Two studies from Du and Francis reported the presence of five anthocyanins in the fruit, namely, delphinidin 3-galactoside, cyanidin 3-galactoside, cyanidin 3-rhamnosylgalactoside, pelargonidin 3-galactoside, and pelargonidin 3-rhamnosylgalactoside [18, 19]. Cyanidin 3-glucoside, cyanidin 3-rutinoside, and pelargonidin 3-glucoside were identified by Tural and Koca [15], with pelargonidin 3-O-glucoside being the most abundant followed by cyanidin 3-O-β-D-galactoside. Pelargonidin 3-O-rutinoside was present only in trace amounts [17]. Delphinidin 3-O-β-galactopyranoside,
cyanidin 3-O-β-galactopyranoside, and pelargonidin 3-O-β-
galactopyranoside were also identified in C. mas fruit [3].

Eight flavonoids have been previously isolated from the methanolic extract of C. mas fruit. These include aro-
madendrin 7-O-β-D-glucoside, quercetin 3-O-β-D-xylloside, quercetin 3-O-α-L-rhamnoside, quercetin 3-O-rutinoside, quercetin 3-O-β-D galactoside, quercetin 3-O-β-D-glucose, quercetin 3-O-β-D-glu-
cose, and kaempferol 3-O-β-galactoside [17]. Fatty acids identified in the fruit include lauric acid, myristic acid, pentadecanoic acid, palmitic acid, palmitoleic acid, stearic acid, oleic acid, vaccenic acid, linoleic acid, linolenic acid, and cis-10,12-octadecadienoic acid [9].

Cornus is widely considered to be an iridoid rich gen-
era. However, there is very little information regarding
the occurrence of iridoids in C. mas. Only two iridoids,
secologanin and loganic acid, have been previously reported
to occur in C. mas, with only one being reported for the fruit [20–22]. The current investigation was prompted by a
lack of information on taxonomically critical and biologically
active iridoids in C. mas fruit. The aim of this study is to
identify more phytochemical compounds in the C. mas fruit,
particularly bioactive iridoids, by using ultra performance liquid chromatography (UPLC) coupled with photodiode
array spectrophotometry (PDA) and electrospray time-of-
flight mass spectrometry (ESI-TOF-MS).

2. Materials and Methods

2.1. Chemicals and Standards. Optima acetonitrile (MeCN, lot no. 125783), methanol (MeOH, lot no. 124876), and forminic acid of LC-MS grade were purchased from Fisher
Scientific Co. (Fair Lawn, NJ, USA). Chromasolv® Water
(H₂O, lot no. SHBB9224V) of LC-MS grade was purchased
from Sigma-Aldrich (St. Louis, MO, USA). Tartaric acid,
malic acid, chlorogenic acid, gallic acid, and rutin standards
were purchased from Sigma-Aldrich (St. Louis, MO, USA).
Citric acid was purchased from Fisher Scientific Co. Loganic
acid was obtained from ChromaDex (Irvine, CA, USA).
Loganin, sweroside, and cornuside were purchased from
Chengdu Biopurify Phytochemicals Ltd (Sichuan, China).
The purities of all standards were higher than 98%. The
standards were accurately weighed and then dissolved in
an appropriate volume of MeOH to produce corresponding
stock standard solutions. Working standard solutions were
prepared by diluting the stock solutions with MeOH at
different concentrations. All stock and working solutions
were maintained at 0°C in a freezer.

2.2. Sample Collection and Preparation. C. mas fruit samples were collected from wild trees in the mountains near Kas-
tamoun, Turkey, in 2012. A voucher specimen is deposited in Research and Development Department laboratory of
Morinda Inc. (American Fork, Utah, USA). The raw fruits
were mashed into puree and the seeds were removed. One
gram of mashed fruit puree was weighed accurately and 9 mL
of 50% MeOH in H₂O was added. The mixture was sonicated
for 30 minutes and then centrifuged. The supernatant was
transferred into a volumetric flask and volume brought to
10 mL with 50% MeOH in H₂O. All samples were filtered
through a nylon microfilter (0.45 μm pore size) before UPLC
analysis.

2.3. Instrumentation and Chromatographic Conditions. Anal-
yses were performed with an Agilent 1260 Infinity LC System
coupled to an Agilent 6230 time-of-flight (TOF) LC/MS System (Agilent Technologies, Santa Clara, CA). The Agilent
1260 LC module was coupled with a photodiode array (PDA)
detector and a 6230 time-of-flight MS detector, along with a
binary solvent pump and an autosampler. Chromatographic
separations were performed with an Atlantis reverse phase
C18 column (4.6 mm × 250 mm; 5 μm, Waters Corporation,
Milford, MA, USA). The pump was connected to a gradient
binary solvent system: A, 0.1% formic acid in H₂O (v/v) and
B, 0.1% formic acid in MeCN. The mobile phase was
programmed consecutively in linear gradients as follows:
0–5 min, 98% A and 2% B; 40 min, 70% A and 30% B;
46–52 min, 2% A and 98% B; and 53–55 min, 98% A and
2% B. The ionization source was Agilent Jet Stream, with
electrospray ionization (ESI) negative mode employed for
acquisition of mass spectra. The elution was run at a flow rate
of 0.8 mL/min. UV spectra were monitored in the range of
200 nm and 400 nm. Injection volume was 2 μL for each of
the sample solutions, followed by needle wash. The column
temperature was maintained at 40°C. Nitrogen, supplied by
a nitrogen generator (model no. NM32LA, Peak Scientific
Instruments Ltd, Scotland, UK), was used as the drying
and nebulizer gas. Other MS instrumental conditions are summa-
rized as follows: drying gas temperature and flow rate were
350°C and 11.0 L/min, respectively; nebulizer pressure was
50 psi; sheath gas temperature and flow rate were 350°C and
12.0 L/min, respectively; capillary, nozzle, and fragmentor
voltages were 3500, 500, and 100 V, respectively; skimmer
was 65.0; Oct 1 RF Vp was 750. The instrument state was
set to high resolution mode (4 GHz). Tuning and calibration
were performed before sample runs. Data collection and
integration were performed using MassHunter workstation
software (version B.05.00). The data was collected in the range
of 100 and 1700 m/z.

2.4. Accurate Mass Measurement. Data were stored in both
centroid and profile formats during acquisition. Two inde-
dependent reference lock-mass ions, purine (m/z 119.03632)
and HP-0921 (m/z 966.000725), were employed to ensure
mass accuracy and reproducibility.

2.5. Characterization of Phytochemicals. Identification of phytochemical compounds 1–10 was accomplished by eluci-
dating mass spectral data. Compound identities were then
confirmed by comparing the UPLC retention times and UV
spectra of target peaks with those of reference compounds.

2.6. Primary DNA Damage Test in E. coli PQ37. The SOS
chromotest in E. coli PQ37 was used to determine the
potential for loganic acid, loganin, sweroside, and cornuside
to induce primary DNA damage. This test was carried out
according to a previously developed method [23]. E. coli PQ37

Journal of Analytical Methods in Chemistry
was incubated in LB medium in a 96-well plate at 37°C in the presence of the iridoids for 2 hours. The concentrations tested were 7.81, 15.6, 31.2, 62.5, 125, 250, 500, and 1000 μg mL⁻¹. Following incubation with replicate samples, 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside was added to the wells to detect β-galactosidase enzyme activity, which is induced during SOS repair of damaged DNA. Nitrophenyl phosphate is also added to the wells to measure alkaline phosphatase activity, an indicator of cell viability. The samples were again incubated and the absorbance of each sample, blanks, and controls was measured at 410 and 620 nm with a microplate reader. Vehicle blanks and positive controls, 1.25 μg mL⁻¹ 4-nitroquinoline 1-oxide (4NQO), were included in this test. The induction factor of each material was calculated by dividing the absorbance of the sample at 620 nm by that of the blank, while also correcting for cell viability. Induction factors less than two indicate an absence of genotoxic activity.

2.7. Antigenotoxicity Test in E. coli PQ37. The primary DNA damage test was performed again, similar to the method...
described above. However, the method was modified to include incubation of E. coli PQ37 in the presence of 1.25 μg mL\(^{-1}\) 4NQO with 250 μg mL\(^{-1}\) loganic acid, loganin, sweroside, or cornuside. Induction factors were calculated in the same manner as described above. The percent reduction in genotoxicity was determined by dividing the difference between the induction factor of 4NQO and the blank (induction factor of 1) by the difference between the induction factor of 4NQO plus iridoid sample and the blank. Experiments were performed in triplicate.

### 3. Results and Discussion

Although the application of LC-MS may minimize the need for chromatographic separation, a good LC separation may prevent ion suppression and isobaric interferences in the MS analysis. The UPLC system delivered a more rapid and effective separation than HPLC, especially for the wide range of phytochemicals identified. UPLC also facilitated the simultaneous determination of the phytochemical matrix of our samples. The flow rate, solvent system, and column were optimized for the UPLC system relative to the analysis of phytochemicals in C. mas fruit samples. A moderate flow rate of 0.8 mL/min accommodated electrospray source, column separation and optimized sensitivity and resolution. Better peak shape and resolution for each target peaks, as well as optimal sensitivity for ion detection, were obtained by adding 0.1% formic acid. The column temperature was kept at 40°C to minimize column pressure due to flow rate. A gradient solvent system of MeCN-H\(_2\)O ensured complete separation of target peaks within a limited time frame. The UPLC system delivered good separation and eliminated the overlap of targeted phytochemical peaks.

The time-of-flight mass spectral detector is known for providing accurate and precise mass information. It can accurately measure mass values with a mass error less than 5 ppm. The generation of empirical formulae results in possible identification of phytochemicals by means of elemental composition analysis. Our experiments used electrospray ionization and were operated in negative mode as the interface since it generated higher signal information for the compounds with less interruption compared to positive mode. All other mass spectral parameters, including drying gas flow and temperature, nebulizer pressure, and sheath gas...

*Iridoid concentration; 4NQO concentration is 1.25 µg mL⁻¹.

flow and temperature, were also optimized in order to achieve good sensitivity and resolution.

The total ion chromatogram (TIC) of C. mas fruit is shown in Figure 1. Negative ion electrospray LC-MS chromatograms of the fruit puree resulted in the identification of 10 peaks. Deprotonated molecular ions [M – H]⁻, chlorinated ions [M + Cl]⁻, and/or formic acid adducts [M + HCOO]⁻ of the compounds were identified with the TOF detector. As a result, accurate molecular weights were determined. Since peaks 6, 7, and 9 were not clearly visible on the TIC chromatogram due to their low concentration, zoomed-in peaks are provided accordingly.

Accurate mass spectra (mass-to-charge, m/z) of the phytochemical peaks identified are shown in Figure 2. Peaks 1–4 were compounds that eluted early from the column. Peaks 1, 3, and 4 had deprotonated molecular ions [M – H]⁻ with m/z values of 149.0099, 191.0201, and 169.0146, respectively, corresponding to the molecular formula of C₇H₆O₃, C₈H₆O₂, and C₇H₆O₂. Peak 2 had [M – H]⁻ and [M + Cl]⁻ with m/z values of 133.0145 and 168.9898, respectively, matching the molecular formula C₇H₆O₃. Compound 6 had [M – H]⁻ and [M + HCOO]⁻ at m/z 353.0884 and 399.0936, corresponding to C₁₆H₂₄O₁₀. Comparisons against reference compound retention revealed that peaks 1–4 and 6 were organic acids, namely, tartaric acid (1), malic acid (2), citric acid (3), gallic acid (4), and chlorogenic acid (6). By the same methods, peak 9 was determined to be rutin (9), a flavonoid glycoside.

Peak 5 is a major peak on the chromatogram, eluting at 22.345 min and displaying both [M – H]⁻ and [M + Cl]⁻ at m/z 375.1319 and 411.1069. Its molecular formula was determined to be C₁₆H₂₄O₁₀. Peak 7 showed [M – H]⁻ and [M + HCOO]⁻ at m/z 389.1455 and 435.1512. Peak 8 exhibited a deprotonated m/z, a chlorinated m/z, and a formic acid adduct of 357.1196, 393.0964, and 403.1252, respectively. Peak 10 had deprotonated ions with m/z value of 541.1569. By comparing these pieces of information with UV and mass spectra, as well as retention times of reference compounds, peaks 5, 7, 8, and 10 were identified as the iridoids loganic acid (5), loganin (7), sweroside (8), and cornuside (10). A summary of the chromatographic and mass spectral data of the phytochemical compounds identified in C. mas fruit is given in Table 1. Chemical structures of the iridoids in C. mas fruit are provided in Figure 3.

These iridoids have displayed many potential biological activities. Loganic acid has potent anti-inflammatory activity [24]. Loganin and sweroside were observed to have strong antibacterial, antifungal, and antispasmodic activities [25]. Loganin was also found to have neuroprotective effects [26]. Cornuside has remarkable antioxidant activity and may provide protection against acute myocardial ischemia and reperfusion injury [27].

In the primary DNA damage test in E. coli PQ37 (Table 2), the mean induction factors for loganic acid, loganin, sweroside, and cornuside, at 1000 µg mL⁻¹, were 1.095, 0.995, 1.028, and 1.068, respectively. At all concentrations tested, these iridoids did not induce any SOS repair at a frequency significantly above that of the blank. Statistically, induction factors were not different from that of the blank, and all results remained well below the twofold criteria for genotoxicity.
SOS chromotest results have a high level of agreement (86%) with those from the reverse mutation assay [28]. Therefore, the SOS chromotest has some utility in predicting potential mutagenicity, in addition to primary DNA damage. These results are consistent with previously published genotoxicity tests of other food derived iridoids [29].

In the antigenotoxicity test, 4NQO exhibited obvious genotoxicty, inducing SOS repair more than 3-fold above that of the vehicle blank. Incubation with loganic acid did not significantly reduce 4NQO induction factors. However, loganin, sweroside, and cornuside apparently reduced the amount of 4NQO that caused DNA damage, as mean induction factors were lowered to below 3 in cells incubated in the presence of these iridoids (Table 3).

4. Conclusions

The UPLC-TOF-MS method reported has been shown to be useful for secondary metabolite profiling of *Cornus mas* fruit. With this method, a total of ten phytochemicals were identified, including five organic acids and four iridoids. To our knowledge, this is the first time that 1–4 and 6–10 have been identified in *C. mas* fruit. Loganic, sweroside, cornuside, and loganic acid will provide valuable information for chemical taxonomy. Iridoids, together with other characteristic components, can be used for identification, authentication, and standardization of *C. mas* fruit raw materials and commercial products. The iridoids in the fruit did not display any toxicity. On the other hand, these iridoids exhibited potential anti-genotoxic activity. Our findings also warrant future research on the safety and efficacy of *C. mas*.
