The study compares the growth, yield, and proximate composition of *Amaranthus hybridus*, *Amaranthus cruentus*, and *Amaranthus deflexus*, grown with poultry manure and NPK in relation to the unfertilized soil of Ilorin, Nigeria. Viable seeds of the Amaranths raised in nursery for two weeks were transplanted (one plant per pot) into unfertilized soil (control) and soils fertilized with either NPK or poultry manure (PM) at 30 Kg ha⁻¹ rate arranged in randomized complete block design with four replicates. Data were collected on plant height, stem girth, number of leaves, leaf area, and number of branches from 1 week after transplanting (1 WAT). Fresh weight, dry weight, and proximate composition were determined at 6 WAT. Except for the length, breadth, and number of leaves, the order of growth parameters and yield in the three *Amaranthus* species was NPK > PM > control. NPK grown *Amaranthus* species had the highest protein while PM-grown vegetables had the highest ash content. Crude fibre in *A. cruentus* grown with PM was significantly higher than NPK and the control. The NPK treatment of *A. hybridus* and *A. deflexus* had the highest crude fibre content. NPK and PM favoured growth and yield of the *Amaranthus* species but influenced proximate composition differently.

1. Introduction

In Nigeria, as in most other tropical countries of Africa where the daily diet is dominated by starchy staple foods, vegetables are the cheapest and most readily available sources of important proteins, vitamins minerals, and essential amino acids [1]. Of all vegetables, *Talinum triangulare*, *Telfaria occidentalis*, *Corchorus olitorius*, *Vernonia amygdalina*, and *Amaranthus* species such as *A. hybridus*, *A. cruentus*, *A. caudatus*, and *A. deflexus* are mostly consumed. The production and nutritional values of these vegetables are limited due to the low fertility of native soils in most parts of Nigeria [2]. The use of inorganic fertilizer to increase yield has been found to be effective only within few years, demanding consistent use on long-term basis [3]. The hazardous environmental consequences and high cost of inorganic fertilizers make them not only undesirable but also uneconomical and out of reach of the poor farmers who still dominate the Nigerian

agricultural sector [4]. This has led to increased use of organic manure, a readily available alternative, which proves more environmentally friendly.

In recent times, attention has been directed towards organic manure because of the rising cost of inorganic fertilizers coupled with their inability to give the soil the desired sound health. Poultry manure, sometimes called chicken manure, is an excellent soil amendment that provides nutrients for growing crops and also improves soil quality when applied wisely, because it has high organic matter content combined with available nutrients for plant growth [5]. The chemical composition of poultry manure varies with factors such as source of manure, feed of the birds, age and condition of the birds, storage, handling of manure, and litter used [6]. Poultry waste consists of droppings, wasted feed, broken eggs, feathers, and sometimes sawdust from poultry floor. It also includes the dead birds and hatchery waste, all of which are high in protein and contain substantial amount

of calcium and phosphorus due to high level of mineral supplement in their diet. Poultry manure has been reported to contain more plant nutrients than all other organic manures [7].

At present, vegetable farmers mostly apply poultry manure in combination with inorganic nitrogen-based fertilizers such as Urea and NPK [8], often because poultry manure alone is believed to dissolve slowly and may not meet up the yield of vegetables. There is a need to determine the independent influence of poultry manure and inorganic nitrogen fertilizer such as NPK on the growth, yield, and nutritional quality of fast-growing vegetables like *Amaranthus* species as to justify the continuous mixture of both or otherwise. The present study compares the growth, yield, and proximate composition of three *Amaranthus* species—*A. hybridus*, *A. cruentus*, and *A. deflexus*, grown with poultry manure, NPK in relation to the unfertilized (control) soil.

2. Materials and Methods

The potted experiment was set up in a screen house in 2013 at the University of Ilorin (N 08° 28' 53.3'', E 04° 40' 28.9''), Ilorin, Nigeria which lies in the southern guinea savanna belt of Nigeria. The annual rainfall in the area is about 1200 mm and temperature varies between 33°C and 34°C during the year, with a distinct dry season from December to March.

The effects of inorganic fertilizer (NPK—15:15:15) and organic fertilizer (poultry manure) were tested on growth, yield, and proximate composition of three species of *Amaranthus*—*A. cruentus*, *A. hybridus*, and *A. deflexus*. Viable seeds of the three species were obtained from the National Centre Genetic Research and Biotechnology, Moor Plantation, Ibadan, Nigeria. Seed viability testing was determined using floatation method [9]. The seeds were raised in nursery for two weeks and one plant per pot (0.30 m by 0.38 m diameter by depth) was transplanted into the unfertilized soil (control) and soils fertilized with either NPK or poultry manure (PM) at 30 kg·ha⁻¹ rate incorporated into 12 kg top soil. The treatments were arranged in a randomized complete block design with four replicates. Weeds were handpicked and irrigation was done regularly at the same rate. Data collection on plant height, stem girth, number of leaves, leaf area, and number of branches was started 1 week after transplanting. The plants were harvested 6 weeks after transplanting and weighed fresh and dried. The proximate composition of moisture, protein, ash, fibre, and carbohydrate content was determined. The moisture content determination was done according to the method described by [10]. The crude protein, calculated from 6.25 × % nitrogen, was determined by micro-Kjeldahl procedure of digestion, distillation, and titration according to AOAC procedure [11]. The ash content was expressed as the percentage weight of ash produced to

original weight of dried sample dry ash in muffle furnace at 600°C [10]. Crude fibre determination was carried out on 2 g fat-free samples obtained after crude fat determination using Soxhlet procedure [12]. Total carbohydrate was calculated as the difference between 100 and the sum of the moisture, protein, fat, fibre, and ash contents [13]. Analysis of variance was performed on the data and means were separated using Duncan's multiple range test.

3. Results

The inorganic (NPK) and organic fertilizer (PM) generally increased the growth of all the species of *Amaranthus* in this study. This was revealed by the growth and luxuriance of the three *Amaranthus* species planted with fertilizers in the weeks after transplanting (WAT). However, NPK-grown *A. hybridus* and *A. cruentus* had fewer leaves than PM and the control. The NPK treatment of *A. deflexus* was significantly lower than the control only at 2 and 3 WAT (Table 1). Leaf length in the NPK-grown *A. hybridus* and *A. cruentus* was initially shorter than that in PM and control (1 WAT and 2 WAT) but it had the longest leaves at 6 WAT. *A. deflexus* grown with NPK had the longest leaves except at 2 and 3 WAT (Table 2). Results of leaf breadth in the three species were similar to those of leaf length as *A. cruentus* in the NPK-fertilized soil was initially lower than that in PM

and control (at 2 WAT) but higher at later weeks (Table 3). Of the three treatments, plant height of *A. hybridus* in NPK-treated soil was shortest from 1 WAT to 3 WAT, but this difference was only significant at 3 WAT. *A. cruentus* in NPK- and PM-fertilized soils was significantly shorter than that of the control at 2 WAT but taller at 6 WAT. *A. deflexus* in the soil amended with NPK was shortest at 6 WAT (Table 4). The slow response of plants in the NPK-treated soil during the initial stage of the experiment may have influenced the stem girth of *A. hybridus* and *A. cruentus* at 1-2 WAT and 1 WAT, respectively, which had slimmer girths. *A. deflexus* in PM-treated soil had slimmer girths when compared with the control plants from 1 WAT to 3 WAT (Table 5). Only *A. hybridus* in NPK-treated soil had branches at 3 WAT, and the number was significantly different from PM and the control at 6 WAT. Only *A. deflexus* had branches at 2 WAT, with the NPK treatment having the significantly highest number of branches at 2 WAT and 3 WAT (Table 6). The weights (fresh and dry) of plants in the NPK-treated soil were significantly higher than PM and the control in all three species. The order of fresh weight and dry weight was similar in all the three *Amaranthus* species. *A. hybridus* had the highest fresh and dry weights of 66.52 ± 7.84 g and 36.23 ± 4.24 g, respectively (Figure 1).

The proximate composition in all three species of *Amaranthus* due to the soil amendments varied for all parameter

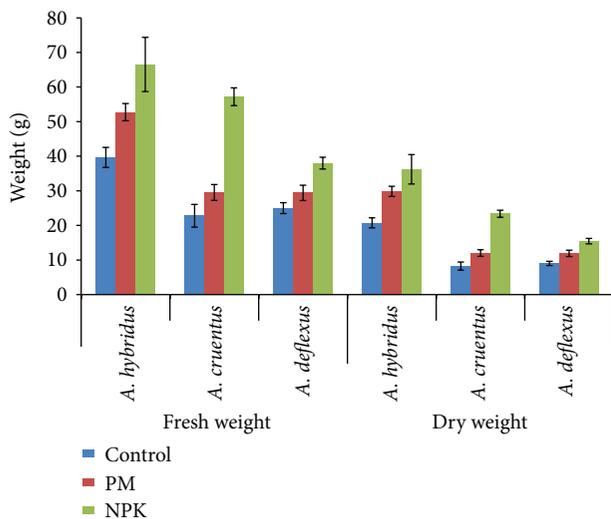

FIGURE 1: Fresh and dry weights of three amaranths grown in fertilized and unfertilized soil.

measured. Except for *A. hybridus*, protein content in the species grown in NPK-treated soil was significantly higher than that of other treatments, while plants in PM-treated soils had the highest ash content. Crude fibre in *A. cruentus* grown

with PM was significantly higher than NPK and the control, contrary to that in *A. hybridus* and *A. deflexus* with the NPK treatment having the highest crude fibre. *A. hybridus* and *A. cruentus* grown with NPK had the higher lipid content than PM and the control, but *A. deflexus* from PM-treated soil had the highest lipid content. Except for *A. hybridus*, the carbohydrate contents in the *Amaranthus* grown with NPK were significantly lower than the control and PM. The moisture contents in these plants were also significantly lower than the control (Table 7). Generally, the protein and fibre contents in *A. hybridus* were significantly higher than those in *A. cruentus* and *A. deflexus*. But ash, lipid, and carbohydrate contents in all three species as well as the moisture content in *A. cruentus* and *A. deflexus* were at par (Figure 2).

4. Discussion

The slower growth in plants in NPK- and PM-fertilized soil during the early weeks after transplanting could be due to initial physiological changes associated with transplanting. This initial drawback after transplanting have been reported for tomato [14], rice [15], maize [16], and sorghum [17]. This effect was outweighed during the later weeks after transplanting (4–6 WAT) as N, P, and K release after mineralization significantly enhanced the growth parameters (leaf number, length and breadth, plant height, branching, and stem girth)

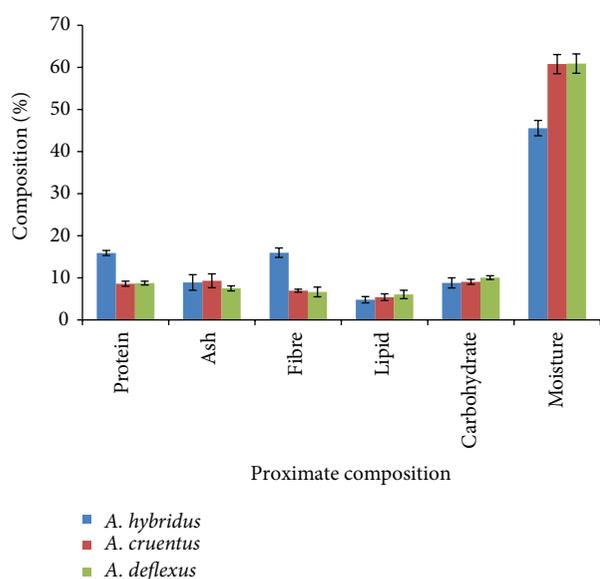

FIGURE 2: Proximate composition of *A. hybridus*, *A. cruentus*, and *A. deflexus*.

in the three *Amaranthus* species. The higher performance of crops in NPK over PM is indicative of the ease of dissolution of nutrients in the inorganic fertilizer being in a more soluble form. Poultry manure also contains useful soil nutrients that are needed for the growth of plants [18], but their composition is in the crude form that is released slowly to the soil [19]. This possibly accounted for slower growth of plants in PM-treated soil to those of NPK and its higher performance than the control. This influence on growth by NPK and PM possibly resulted in higher yield than in the control. This result corroborates those of [4, 20, 21] on growth of *Amaranthus* and that of [22] on yield of *Amaranthus*.

The higher protein in the *Amaranthus* species grown with NPK and PM is consistent with the result of [22]. The increased nitrogen to the soil by the fertilizers increased the uptake by the *Amaranthus* resulting in increased protein. The ash content in PM plants was significantly higher possibly because of the balanced nutrient in the manure, unlike NPK with proportionate contents of N, P, and K and the control

with lower concentration of nutrients. The significantly higher carbohydrate in the control plants of *A. cruentus* and *A. deflexus* also corroborates with those of [22]. Except for moisture content, the protein, fibre, fat, and carbohydrate composition in the three species were higher than those reported by [23]. The nutritional content of *A. cruentus* except for lipid was lower than that reported by [24]. Of the three species, only *A. hybridus* is considered a good source of protein as it accounts for more than 12% of its nutritional value [25]. This is contrary to the report by [1] in which *A. cruentus* was implicated as a rich source of protein accounting for 11.4%–14.1% of the proximate composition.

5. Conclusion

Except for the length, breadth, and number of leaves, growth parameters and yield were in the order NPK > PM > control. *Amaranthus* species grown with NPK significantly had higher protein, while those grown with PM had higher ash content. *A. hybridus* had the highest protein composition and could be considered a good source of vegetable protein when consumed. Both inorganic fertilizer (NPK) and organic (PM) increase soil fertility, but plants grown with inorganic fertilizer performed better. Since the *Amaranthus* grown with NPK and PM had better growth but differs in nutritional quality, the choice of the nutrient may influence determining the choice of manure to encourage.
