Received 18 September 2008; Accepted 4 November 2008

Abstract: The oxidation of 4-hydroxycoumarin (HDC) by diperiodatonicelkate(IV) (DPN) in aqueous alkaline medium at a constant ionic strength of 1.0 mol dm$^{-3}$ was studied spectrophotometrically at 298 K. The reaction between DPN and 4-hydroxycoumarin in alkaline medium exhibits 1:3 stoichiometry (HDC: DPN). The reaction is of first order in [DPN] and has less than unit order in [HDC] and fractional order in [alkali]. The oxidation reaction in alkaline medium has been shown to proceed via a DPN-4-hydroxycoumarin complex, which decomposes slowly in a rate-determining step followed by other fast steps to give the products. The main products were identified by spot test, IR, $^1$HNMR studies. The reaction constants involved in the different steps of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated. The activation parameters with respect to slow step of the mechanism were calculated.

Keywords: Oxidation, Mechanism, 4-Hydroxycoumarin, Diperiodatonicelkate(IV).

Introduction

The use of diperiodatonicelkate(IV) (DPN) as an oxidant in an alkaline medium is restricted to a few cases due to its limited solubility and stability in aqueous medium$^{1-5}$. Reduction of nickel(IV) complexes has received a considerable attention to understand the nature of intermediate oxidation states of nickel such as nickel(III). Indeed, stable nickel(III) complexes are known$^{6,7}$. Moreover, when nickel(IV) periodate is oxidant, it needs to be known which of the species is the active form of oxidant, since multiple equilibria between the different nickel(IV) species are involved.
The biological importance of coumarin derivatives as anticoagulants, aflatoxins, mycotoxins and antibiotics has led to a considerable amount of synthetic work in the field of coumarin for their pharmacological evaluation. 4-Hydroxycoumarin (4-hydroxy-2H-1-benzopyran-2-one) (HDC) is used in the synthesis of pharmaceuticals especially for anticoagulants. It is used in the manufacturing fluorescent dyes and rodenticides. The 4-hydroxycoumarin derivative, mercamour, is a long oral anticoagulant activity is in the duration of 48-72 hours. Ichikawa et al. reported that 4-hydroxy-3-sulphonamidocoumarins are used as antibacterial and antitubercular agents.

In earlier reports on DPN oxidation, periodate had a retarding effect and order in the [alkali] was found to be less than unity in almost all the reactions and monoperodatonicelate(IV) (MPN), is considered to be the active species. However, in the present study we have observed entirely different kinetic observations and diperiodatonicelate(IV) (DPN) itself is found to be active form of the oxidant. The literature survey reveals that there are no reports on the mechanistic study of oxidation on 4-hydroxycoumarin by DPN. Thus, in order to explore the mechanism of oxidation by DPN in alkaline medium and to check the reactivity of hydroxy compounds towards DPN, we have selected 4-hydroxycoumarin as a substrate. The title reaction is studied to investigate the redox chemistry of the nickel(IV) in such media and to arrive at a plausible mechanism.

**Experimental**

All chemicals used were of regent grade. Double distilled water was used throughout the experiment. The solution of 4-hydroxycoumarin (M/s. S.S. Antibiotics Pvt. Ltd., Aurangabad, India) was prepared by dissolving appropriate amount of recrystallised sample (from aqueous acetone) in alkali. The solid complex nickel(IV) periodate was prepared by known method. The purity of the complex was checked by its UV-vis spectrum, which shows a broad absorption band at 410 nm. Aqueous solution of DPN was obtained by dissolving the solid complex in 1.0 mol dm$^{-3}$ KOH solution. The Ni(IV) in alkaline solution was estimated gravimetrically after reducing it to Ni(II) and precipitating Ni(II) as its dimethyl glyoxime complex. Periodate solution was prepared by weighing out the required amount of a sample potassium periodate in hot water and was used after keeping for 24 hours to attain the equilibrium. Its concentration was ascertained iodometrically at neutral pH maintained by a phosphate buffer. Nickel(II) solution was prepared from nickel sulphate (Fischer). Potassium hydroxide and potassium nitrate were employed to maintained required alkalinity and ionic strength respectively. Since, periodate is present in excess in the DPN complex, the possibility of 4-hydroxycoumarin oxidation by periodate in aqueous alkaline medium has been tested. The results indicated that the reaction between IO$_4^-$ and 4-hydroxycoumarin is negligibly slow compared to the rate of reaction between DPN and 4-hydroxycoumarin under the experimental conditions.

**Kinetic measurements**

Kinetic measurements were performed on a Hitachi 150-20 spectrophotometer. All kinetic runs were followed under pseudo-first order conditions with the 4-hydroxycoumarin concentrations in excess over that of the oxidation at 25±0.1 °C, unless otherwise stated. The reaction was initiated by mixing thermally equilibrated solutions of DPN and 4-hydroxycoumarin, which also contained a definite quantity of KOH, KNO$_3$ and KIO$_4$. Here the total concentration of hydroxide ion was calculated considering the KOH in DPN as well as the KOH additionally added. Similarly, the total mataperiodate concentration was calculated by considering the amount present in the DPN solution and that additionally added. The course of reaction was followed by measuring the absorbance of unreacted DPN in the reaction mixture.
Mechanistic Study on the Oxidation of 4-Hydroxycoumarin

in a 1 cm quartz cell located in the thermostatted compartment of a spectrophotometer, at its maximum absorption wavelength of 410 nm as a function of time. Earlier, it was verified that there is negligible interference from other species present in the reaction mixture at this wavelength. The obedience of Beer’s law by DPN at 410 nm was verified earlier and the molar absorbance coefficient, $\epsilon$ was found to be $7500 \pm 375$ dm$^3$ mol$^{-1}$ cm$^{-1}$ at this wavelength. The reaction was followed to more than 80% completion. The first order rate constants, $k_{obs}$, were calculated from the slopes of log [DPN] vs. time plots. The rate constants were reproducible to within ±5%.

In view of the modest concentration of alkali used in the reaction medium, attention was also directed to the effect of the surface reaction vessel on the kinetics. Use of polythene or acrylic wares and quartz or polyacrylate cells gave the same results, indicating that the surface does have any significant effect on the reaction rates. Kinetic runs were also carried out in the nitrogen atmosphere in order to understand the effect of dissolved oxygen on the rate of the reaction. No significant difference in the results was obtained under a nitrogen atmosphere and in the presence of air. In view of the ubiquitous contamination of carbonate in the basic medium, the effect of carbonate was also studied. Added carbonate had no effect on the reaction rates. However, fresh solutions were, nevertheless, used while carrying out the kinetic study. Regression analysis of experimental data to obtain regression coefficient $r$ and the standard deviation $S$, of points from the regression line, was performed with the Microsoft Excel program.

**Results and Discussion**

**Stoichiometry and product analysis**

Different reaction mixtures with different sets of concentrations of reactants, where [Ni(IV)] was in excess over 4-hydroxycoumarin at constant amount of ionic strength, alkali and periodate were kept for about 6 hours at 25 ± 0.1 °C in nitrogen atmosphere and in a closed vessel. The remaining [DPN] was assayed spectrophotometrically by measuring the absorbance at 410 nm. The results indicated the 3 moles of DPN is consumed by 1 mole of 4-hydroxycoumarin as in equation (1).

$$+ 3 \text{Ni(IV)} + 4 \text{OH} \rightarrow \text{4-hydroxycoumarin} + 3 \text{Ni(II)} + 2 \text{H}^+$$

The reaction product was extracted with ether and recrystallised from aqueous alcohol and the purity was checked by HPLC. This was identified as salicylic acid by its IR spectrum (KBr) from FTIR Spectrometer Nicolet Impact 410, which showed a band at (v) 1701 cm$^{-1}$ due to C=O and 3392 cm$^{-1}$ due to phenolic OH. Salicylic acid was further characterized by $^1$H NMR spectrum from NMR Spectrometer Bruker-F300MHz (CDCl$_3$ +DMSO-d$_6$/TMS) $\delta$, 5.74 (s, 1H, phenolic OH, D$_2$O exchangeable), 7.27-7.82 (m, 4Ar H), 11.5 (s, 1H, acidic OH, D$_2$O exchangeable). The other product was oxalic acid, which is highly soluble in water, was identified by spot test$^{12}$ and Ni(II) sulphate was identified by spot test$^{13}$ and UV-Vis spectrum. It was observed that the salicylic acid and oxalic acid do not undergo further oxidation under the present kinetic conditions.

**Reaction orders**

The reaction orders were determined from the slope of log $k_{obs}$ vs. log (concentration) plots by varying the concentrations of 4-hydroxycoumarin, alkali and periodate in turn while keeping all other concentrations and conditions constant.
Effect of [diperiodatonicelate(IV)]
The oxidant DPN concentration was varied in the range of \(1.0 \times 10^{-5}\) to \(1.0 \times 10^{-4}\) mol dm\(^{-3}\) and the fairly constant \(k_{\text{obs}}\) values indicate that order with respect to [DPN] was one (Table 1). This was also confirmed by linearity of the plots of log [absorbance] vs. time (\(r \geq 0.986\), \(S < 0.014\)) up to 85% completion of the reaction.

Effect of [4-hydroxycoumarin]
The effect of 4-hydroxycoumarin on the rate of reaction was studied at constant concentrations of alkali, DPN and periodate at a constant ionic strength of 1.0 mol dm\(^{-3}\). The substrate, HDC was varied in the range of \(3.0 \times 10^{-4}\) to \(3.5 \times 10^{-3}\) mol dm\(^{-3}\). The \(k_{\text{obs}}\) values increased with increase in concentration of 4-hydroxycoumarin (Table 1). The order with respect to [HDC] was found to be less than unity (\(r \geq 0.995\), \(S \leq 0.009\)). This is also confirmed in the plots of \(k_{\text{obs}}\) vs. [HDC]\(^{0.51}\), which is linear rather than the direct plot of \(k_{\text{obs}}\) vs. [HDC] in Figure 1.

![Figure 1. Plot of \(k_{\text{obs}}\) vs [HDC]\(^{0.51}\) and \(k_{\text{obs}}\) vs [HDC].](image)

Effect of [alkali] and [periodate]
The effect of increase in concentration of alkali on the reaction was studied at constant concentrations of 4-hydroxycoumarin, DPN and periodate at a constant ionic strength of 1.0 mol dm\(^{-3}\) at 25 °C. The rate constants increased with increase in alkali concentration (Table 1), indicating fractional order dependence of rate on alkali concentration (\(r \geq 0.988\), \(S \leq 0.007\)). The effect of periodate was observed by varying the periodate concentration from \(1.0 \times 10^{-5}\) to \(1.0 \times 10^{-4}\) mol dm\(^{-3}\) keeping all other reactant concentrations constant. It was found that the added periodate had no effect on the rate of reaction (Table 1).

Effect of dielectric constant of the medium (D) and ionic strength (I)
The relative permittivity (\(\varepsilon_T\)) effect was studied by varying the \(t\)-butanol-water content in the reaction mixture with all other conditions being constant. Attempts to measure the relative permittivity of the mixture of \(t\)-butanol-water were not successful. However, they were computed from the values of pure liquids\(^{14}\). The solvent did not react with the oxidant under the experimental conditions. The rate constants, increased with decreased in the dielectric constant of the medium. The plot of log \(k_{\text{obs}}\) vs. \(1/\varepsilon_T\) was linear with positive slope as shown in Figure 2 (\(r \geq 0.9887\), \(S \leq 0.013\)). The effect of ionic strength was studied by varying the
Mechanistic Study on the Oxidation of 4-Hydroxycoumarin

potassium nitrate concentrations from 0.50 to 2.0 mol dm\(^{-3}\) at constant [DPN], [HDC], [OH\(^-\)] and [IO\(_4^-\)]. It was found that the rate constant increased with increase in concentrations of KNO\(_3\) and the plot of log \(k_{obs}\) vs. \(\sqrt{I}\) was linear with positive slope, which is given in Figure 2 (\(r \geq 0.988, S < 0.007\)).

Table 1. Effect of [DPN], [HDC], [IO\(_4^-\)] and [OH\(^-\)] on diperiodatonickelate(IV) oxidation of 4-hydroxycoumarin alkaline medium at 25 °C, \(I = 1.0 \text{ mol dm}^{-3}\).

Figure 2. Effect of solvent polarity (\(\varepsilon_T\)) and ionic strength (I) on the oxidation of 4-hydroxy coumarin by diperiodatonickelate(IV) in aqueous alkaline medium at 25 °C.
Effect of initially added products
The externally added products, such as the nickel sulphate, oxalic acid and salicylic acid did not have any significant effect on the rate of the reaction.

Polymerization study
To test the intervention of free radicals, the reaction mixture was mixed with acrylonitrile monomer and kept for 4 hours under nitrogen atmosphere. On dilution with methanol, no precipitate was formed, indicating the absence of free radicals in the reaction.

Effect of temperature (T)
The kinetics was studied at four different temperatures (298, 303, 308 and 313) K under varying concentrations of 4-hydroxycoumarin alkali and periodate, keeping other conditions constant. The rate constants were found to increase with increase in temperature. The rate constants (k) of the slow step of Scheme 1 were obtained from the slopes and intercepts of \(1/k_{\text{obs}}\) vs. \(1/[\text{HDC}]\) and \(1/k_{\text{obs}}\) vs. \([\text{OH}^-]\) plots at four different temperatures and were used to calculate the activation parameters. The energy of activation corresponding to these constants was evaluated from the Arrhenius plot of \(\log k\) versus \(1/T\) (\(r \geq 0.976, S < 0.009\)) and other activation parameters obtained are tabulated in Table 2.

Table 2. Thermodynamic activation parameters for the oxidation of 4-hydroxycoumarin by DPN in aqueous alkaline medium with respect to the slow step of scheme 2.

The water soluble\(^{6,7}\) nickel(IV) periodate complex is reported\(^{5,15-16}\) to be [Ni(HIO\(_6\))(OH)\(_2\)]\(^{6-}\). Although periodate is involved in multiple equilibria (2)-(4), which prevail to varying extents depending on the pH employed, under the strong alkaline conditions of the study (pH 13.3) the predominant form of periodate is expected to be H\(_3\)IO\(_6\)\(^{2-}\) and not HIO\(_6\)\(^{4-}\), which appears in present in the Ni(IV) complex\(^{4,5,15-16}\). On the contrary, in mild acidic and neutral medium the predominant species of periodic acid is H\(_2\)IO\(_6\)\(^{5-}\).

\[

\end{align*}
\]
Mechanistic Study on the Oxidation of 4-Hydroxy coumarin

The reaction between DPN and 4-hydroxycoumarin in alkaline medium has a 1:3 stoichiometry of reductant to oxidant with first order dependence on both [DPN] and the apparent order of less than unity in [OH\(^-\)] and [HDC]. In most of the reports\(^ {5,6}\) on DPN oxidation, periodate had a retarding effect and order in the [OH\(^-\)] was found to be less than unity and monoperiodatonicelicate(IV) (MPN), is considered to be the active species. However, in the present kinetic study, different kinetic observations have been obtained i.e., periodate has totally no effect on the rate of the reaction. Accordingly DPN itself is considered to be the active species of oxidant. The results indicate that the DPN combines with alkali to form a deprotonated form of DPN in a prior equilibrium step, which is also supported by the observed fractional order in [OH\(^-\)]. Based on the observed results a mechanism involving complex formation between oxidant and substrate has been proposed which is shown in the Scheme 1. 4-Hydroxy coumarin reacts with one mole of deprotonated form of DPN to form a complex which decomposes in a slow step to give salicylic acid, glycolic acid and nickel(II) species. Further glycolic acid reacts with two more molecules of nickel(IV) species in a fast step to yield the products as oxalic acid.

\[
\text{[Ni(OH)\(_2\)(H\(_3\)IO\(_6\))]\(^{2-}\) + OH} \xrightarrow{K_c} \text{[Ni(OH)\(_2\)(H\(_3\)IO\(_6\))\(_2\)(H\(_3\)IO\(_6\))]\(^{3-}\) + H\(_2\)O}
\]

\[
\xrightarrow{\text{fast}} \text{COOH} \quad \text{CH\(_2\)OH} + 2 \text{[Ni(OH)\(_2\)(H\(_3\)IO\(_6\))]\(^{3-}\)} \xrightarrow{2 \text{ Ni}^{2+} + 2 \text{H}_2\text{IO}_6^{2-} + 2 \text{H}_3\text{IO}_6^{3-}} \text{complex [C]} + 2 \text{H}_2\text{O}
\]

**Scheme 1.** Detailed Scheme for the oxidation of 4-hydroxy coumarin by diperiodatonicelicate(IV).

The direct plot of \(k_{\text{obs}}\) vs [HDC] was drawn to know the parallel reaction if any along with interaction of oxidant and reductant. However the plot of \(k_{\text{obs}}\) versus [HDC] was not linear. Thus, in Scheme 1, the parallel reaction and involvement of two molecules of 4-hydroxy coumarin in the complex are excluded. The probable structure of the complex is given in Scheme 2.

**Scheme 2.** Probable structure of the complex.

Spectral evidence for such an oxidant-substrate complex was obtained from the UV-vis spectra of 4-hydroxy coumarin, mixture of DPN and 4-hydroxy coumarin. A hypochromic shift of about 8 nm from 240 to 232 nm in the spectra of 4-hydroxy coumarin was observed and hyperchromicity was observed at 232 nm. Indeed, it is to be noted that a plot of \(1/k_{\text{obs}}\) vs. \(1/[\text{HDC}]\) shows a straight line with non-zero intercept. Such complex between a substrate and an oxidant has been observed in other studies\(^ {18}\). The Michaelis-Menten plot also proved...
the complex formation between DPN and 4-hydroxycoumarin, which explains the less than unit order dependence on [HDC]. Scheme 1 leads to the rate law,

$$\text{rate} = \frac{d[\text{DPN}]}{dt} = k K_4 K_5 [\text{HDC}] [\text{OH}] [\text{DPN(IV)}]$$  \hspace{1cm} (5)

$$k_{\text{obs}} = \frac{\text{rate} \cdot [\text{DPN}]}{k K_4 K_5 [\text{HDC}] [\text{OH}]} = \frac{k K_4 K_5 [\text{OH}][\text{HDC}]}{1 + K_4 [\text{OH}] + K_5 [\text{HDC}][\text{OH}]}$$  \hspace{1cm} (6)

This explains all the observed kinetic orders of different species. The rate law (6) can be rearranged into the following form, which is suitable for verification:

$$\frac{1}{k_{\text{obs}}} = \frac{1}{k K_4 K_5 [\text{HDC}] [\text{OH}]} + \frac{1}{k K_5 [\text{HDC}]} + \frac{1}{k}$$  \hspace{1cm} (7)

According to equation (7), other conditions being constant, plots of $1/k_{\text{obs}}$ versus $1/[\text{OH}]$ ($r \geq 0.985$, $S \leq 0.014$), $1/k_{\text{obs}}$ versus $1/[\text{HDC}]$ ($r \geq 0.996$, $S \leq 0.012$) and should be linear and is found to be so in Figure 3. The slopes and intercepts of such plots lead to the values of $K_4$, $K_5$ and $k$ as $(1.30 \pm 0.05) \text{ dm}^3 \text{ mol}^{-1}$, $(3.1 \pm 0.2) \times 10^3 \text{ dm}^3 \text{ mol}^{-1}$, $(4.45 \pm 0.5) \times 10^{-3} \text{ s}^{-1}$ respectively. The value of $K_4$ is in good agreement with earlier literature$^{19}$. These constants were used to calculate the rate constants and compared with the experimental values and found to be in reasonable agreement with each other (Table 1), which fortifies the Scheme 1.

![Figure 3](image-url)

**Figure 3.** Verification of rate law (eq. 7). Plots of $1/k_{\text{obs}}$ vs. $1/\text{[HDC]}$ and $1/k_{\text{obs}}$ vs. $1/\text{[OH]}$ (conditions as in Table 1).

The effect of ionic strength and dielectric constant of the medium on the rate explains qualitatively the reaction between neutral and negatively charged ions, as seen in Scheme 1. The proposed mechanism is also supported by the moderate values of thermodynamic parameters. The fairly high positive values of the free energy of activation and enthalpy of activation indicate that the transition state is highly solvated, while $\Delta S^\#$ suggests that the intermediate complex is more ordered than the reactants. The modest value of the enthalpy of activation and the higher rate constant of the slow step of the mechanism indicate that an oxidation presumably occurs by an inner-sphere mechanism. This conclusion is supported by earlier observation$^{20}$. 
Conclusion

Among various species of diperiodatonickelate(IV) in alkaline medium, DPN itself is considered as active species for the title reaction. The results indicate that, the role of pH in the reaction medium is crucial. Rate constant of slow step and other equilibrium constants involved in the mechanism are evaluated and activation parameters with respect to slow step of reaction were computed. The overall mechanistic sequence described here is consistent with product studies, mechanistic and kinetic studies.

Appendix

According to Scheme 1,

$$\text{Rate} = \frac{d[DPN]}{dt} = k[C] = kK_5[HDC][DPN][OH]$$  \hspace{1cm} (I)

$$[DPN] = [Ni(OH)_{2}(H_2IO_6)] + [Ni(OH)_{2}(H_2IO_6)]_{[DPN]} + [C]$$

where t and f refer to total and free concentrations.

Substituting the equations (II), (III) and (IV) in eqn. (I) (omitting the subscripts t and f) we get eqn. (V)

$$k_{obs} = \frac{rate}{[DPN]} = \frac{kK_4K_5[OH][HDC]}{1 + K_4[OH] + K_4K_5[HDC][OH]}$$  \hspace{1cm} (VI)

In view of low concentration of DPN used, the terms ((1+K_4K_5 [DPN][OH]) and (1+K_4 [DPN] + K_4K_5 [DPN][HDC]) approximate to unity. Therefore,

$$k_{obs} = \frac{rate}{[DPN]} = \frac{kK_4K_5[OH][HDC]}{1 + K_4[OH] + K_4K_5[HDC][OH]}$$  \hspace{1cm} (VI)
