Pressure Transient Analysis and Flux Distribution for Multistage Fractured Horizontal Wells in Triple-Porosity Reservoir Media with Consideration of Stress-Sensitivity Effect

1. Introduction

The concept of dual-porosity media was first proposed by Barenblatt et al. [1] to describe naturally fractured media. Warren and Root [2] then extended this model to analyze pressure transient dynamics for vertical wells in naturally fractured oil reservoirs. Recently, Cai et al. [3, 4] analyzed the imbibition mechanism in fractured-porous media based on fractal geometry. Although the dual-porosity model can describe most naturally fractured reservoirs, there are still some drawbacks when applying the dual-porosity model to describe reservoirs with multiple pore media, such as reservoirs with natural fractures and vugs (different from matrix pores).

In order to better describe reservoir heterogeneity in this type of naturally fractured-vuggy reservoirs, the concept of triple-porosity model was proposed. The first triple-porosity model in the literature was proposed by Abadassah and Ershaghi [5], in which the reservoir was represented by a combination of two matrix systems with different properties and uniformly distributed natural fractures. The model was then further extended by Al-Ghamdi and Ershaghi [6] to represent reservoirs with two fracture systems (microfractures and macrofractures) and one matrix system. After that,
over the past several decades, numerous efforts have been made to investigate transient pressure behavior in so-called triple-porosity reservoirs. However, almost all the research focuses on vertical wells [7–19] or horizontal wells [20–22] in triple-porosity reservoirs, and few studies have been done on complex well-reservoir configuration, such as multistage fractured horizontal well in triple-porosity reservoirs.

Field practices have proven that horizontal wellbore combining multistage hydraulic fracturing can effectively enhance the permeability in the vicinity of horizontal wellbore. Almost all the triple-porosity models [23, 24] for fractured horizontal wells assume linear flow, which cannot completely characterize the pressure responses during all flowing periods (such as pseudoradial flow period). On the other hand, in most existing models for fractured horizontal wells in triple-porosity reservoirs three porous media denote hydraulic fractures, natural fractures, and matrix pores, which means the reservoir itself is actually considered as a dual-porosity medium.

This study develops a semianalytical model based on source/sink function theory for analyzing transient pressure responses and flux distribution of naturally fractured-vuggy reservoirs, in which the reservoir itself is conceptualized as triple-porosity media and the interaction between hydraulic fractures and reservoir is considered. The model presented here can completely reflect transient pressure characteristics during all the possible flowing period as well as flux distribution among multiple fractures. In addition, this model also takes into account the stress-sensitivity of permeability caused by closure of natural fractures during production.

2. Physical Model of a Multistage Fractured Horizontal Well in a Triple-Porosity Reservoir

As shown in Figure 1, a horizontal well with multiple hydraulic fractures, producing at a constant rate \( q \) in a reservoir with multiscale storage spaces, is considered here. Both the cap rock and underlying rock formation of the reservoir are usually shales with extremely low permeability, which can be conceived as no-flow boundaries. The reservoir thickness and oil viscosity are assumed to be \( h \) and \( \mu \), separately. Other basic assumptions involved in the derivation of the triple-porosity model are as follows:

(1) The reservoir is assumed to be composed of three contiguous porous media, which are matrix, natural fractures, and vugs (representing larger voids in the reservoir which are not part of natural fractures).

(2) Natural fractures are assumed to be directly connected to hydraulic fractures or the horizontal wellbore, while the fluid stored in matrix pores or vugs does not have direct access to hydraulic fractures or the horizontal wellbore. Figure 2 presents a simple illustration of the fluid flowing path in triple-porosity reservoirs.

(3) The permeability of natural fractures is considered stress-sensitive to incorporate the effect of partial or complete closure of natural fractures during production.

(4) Both oil and rock are considered slightly compressible, and the reservoir has uniform pressure distribution at time zero.

(5) Consider single-phase isothermal flow and negligible gravity and capillary effects.

To obtain the pressure responses caused by the well-reservoir configuration shown in Figure 1, a mathematical model together with corresponding boundary and initial conditions is required. In the problem addressed here, the multiple fractures inner boundary condition is so complex that it is rather difficult to directly describe it with a mathematical equation. In order to solve this problem, source function theory, a powerful tool to solve complex transient flow problems in reservoirs, is adopted in this work. We first studied the transient pressure responses caused by a continuous line-sink in triple-porosity reservoirs and then adopted the line-sink solution with superposition principle to obtain the pressure transient dynamics and flux distribution of multistage fractured horizontal wells in triple-porosity reservoirs.

3. Line-Sink Model in Stress-Sensitive Triple-Porosity Reservoirs

3.1. Physical Model for a Line-Sink in Triple-Porosity Reservoirs. As shown in Figure 3, a continuous line-sink in a triple-porosity reservoir with stress-dependent fracture permeability is considered in this section. The strength of the line-sink is represented by \( \tilde{q}(t) \).
3.2. Mathematical Model for a Line-Sink in Triple-Porosity Reservoirs

(1) Governing Equations. Imposing mass-balance equation over a control volume in the triple-porosity reservoir and substituting equation of state and equation of motion, we can get the governing equations for matrix, natural fracture, and vug systems.

For natural fracture system with stress-dependent permeability, the governing equation is as follows (i.e., (A.26b) in Appendix A):

$$\frac{\partial^2 p_f}{\partial r^2} + \frac{1}{r} \frac{\partial p_f}{\partial r} + \gamma \left( \frac{\partial p_f}{\partial r} \right)^2 = e^{-\gamma (p_r - p_f)} \left[ \frac{\phi_{0f} C_m \mu}{k_h} \frac{\partial p_f}{\partial r} + \frac{\phi_{mf} C_{mf} \mu}{k_h} \frac{\partial p_f}{\partial t} \right].$$

(1)

For matrix system, the governing equation is as follows (i.e., (A.30) in Appendix A):

$$\frac{\phi_{0m} C_{mt} \mu}{k_h} \frac{\partial p_m}{\partial t} + \frac{\alpha_x k_x}{\mu} (p_f - p_m) = 0.$$  

(2)

For vug system, the governing equation is as follows (i.e., (A.34) in Appendix A):

$$\frac{\phi_{0v} C_{vt} \mu}{k_h} \frac{\partial p_v}{\partial t} + \frac{\alpha_x k_x}{\mu} (p_f - p_v) = 0.$$  

(3)

(2) Boundary Conditions. According to the derivation in Appendix B, the inner boundary condition of the line-sink model is (i.e., (B.5) in Appendix B):

$$\lim_{r \to a} e^{-\gamma (p_r - p_f)} \frac{\partial p_f}{\partial r} \bigg|_{r=a} = \tilde{q}(t) \frac{\mu B}{2 \pi k_d h}.$$  

(4)

Assuming infinitely large reservoirs, the outer boundary condition can be expressed as

$$p_f(r, t)\bigg|_{r=\infty} = p_r.$$  

(5)

(3) Initial Condition. The initial pressure distribution in the reservoir is assumed to be uniform, which is

$$p_f(r, t)\bigg|_{t=0} = p_m(r, t)\bigg|_{t=0} = p_v(r, t)\bigg|_{t=0} = p_r.$$  

(6)

3.3. Dimensionless Form of the Line-Sink Model. For the purpose of simplifying derivation and comparing between different reservoirs, the mathematical model is derived and solved in dimensionless form in this work. The pressure drops involved in the mathematical model are \(\Delta p_f = p_f - p_r, \Delta p_m = p_m - p_f, \) and \(\Delta p_v = p_v - p_f, \) and relevant dimensionless variables used in the mathematical model are listed in Table 1.

Obviously, \( \omega_f, \omega_m, \) and \( \omega_v \) in Table 1 satisfy the following equation:

$$\omega_f + \omega_m + \omega_v = 1.$$  

(7)

With the definitions in Table 1, the dimensionless forms of (1)–(6) can be obtained as follows:

$$\frac{\partial^2 p_{fD}}{\partial r_{D}^2} + \frac{1}{r_D} \frac{\partial p_{fD}}{\partial r_D} - \gamma_D \left( \frac{\partial p_{fD}}{\partial r_D} \right)^2 = e^{y_D p_{fD}} \left[ \alpha_f \frac{\partial p_{fD}}{\partial t_D} + \omega_m \frac{\partial p_{mD}}{\partial t_D} + \omega_v \frac{\partial p_{vD}}{\partial t_D} \right],$$

(8)

$$\omega_m \frac{\partial p_{mD}}{\partial t_D} + \lambda_{mf} (p_{mD} - p_{fD}) = 0,$$

(9)

$$\frac{1 - \omega_f - \omega_m}{\omega_f \omega_m} \frac{\partial p_{vD}}{\partial t_D} + \lambda_{vf} (p_{vD} - p_{fD}) = 0,$$

(10)

$$\lim_{r_D \to 0} e^{-\gamma_D p_{fD}} \frac{\partial p_{fD}}{\partial r_D} \bigg|_{r_D=r_D} = -\tilde{q}_D,$$

(11)

$$p_{fD}\bigg|_{r_D=\infty} = 0,$$

(12)

$$p_{fD}\bigg|_{r_D=0} = p_{mD}\bigg|_{r_D=0} = p_{vD}\bigg|_{r_D=0} = 0.$$  

(13)

3.4. Solution of the Dimensionless Line-Sink Model

3.4.1. Pedrosa’s Linearization. The stress-sensitivity of natural fracture permeability makes the above seepage model strongly nonlinear which cannot be solved analytically. Here, following Pedrosa Jr. [25], we introduced the following equation to alleviate the nonlinearity of (8) and (11):

$$p_{fD}(r_D, t_D) = -\frac{1}{y_D} \ln \left[ 1 - y_D U_D(r_D, t_D) \right],$$

(14)

where \( U_D \) is an intermediate dimensionless parameter which is also a function of radial distance and time.

With (14), (8)–(13) become

$$\frac{\partial^2 U_D}{\partial r_D^2} + \frac{1}{r_D} \frac{\partial U_D}{\partial r_D} = -\frac{1}{1 - y_D U_D} \omega_f \frac{\partial U_D}{\partial t_D} + \omega_m \frac{\partial p_{mD}}{\partial t_D} + \omega_v \frac{\partial p_{vD}}{\partial t_D},$$

(15)

$$\omega_m \frac{\partial p_{mD}}{\partial t_D} + \lambda_{mf} \left[ p_{mD} + \frac{1}{y_D} \ln \left[ 1 - y_D U_D \right] \right] = 0,$$

(16)

$$\frac{1 - \omega_f - \omega_m}{\omega_f \omega_m} \frac{\partial p_{vD}}{\partial t_D} + \lambda_{vf} \left[ p_{vD} + \frac{1}{y_D} \ln \left[ 1 - y_D U_D \right] \right] = 0.$$  

(17)

</table>

Note: \( L \) is an arbitrary reference length which can be \( r_w, L_b \), and so forth.

\[
\lim_{\rho_D \to \infty} \frac{\partial U_D}{\partial r_D} \bigg|_{r_D=\rho_D} = -\tilde{q}_D, 
\]

\[
U_D \bigg|_{r_D=\infty} = 0,
\]

\[
U_D \bigg|_{r_D=0} = p_{mD} \bigg|_{r_D=0} = p_\nu \bigg|_{r_D=0} = 0.
\]

### 3.4.2. Perturbation Technique.

According to the perturbation theory, the terms \( U_D, -(1/2) \ln[1-\gamma_D U_D(r_D, t_D)] \), and \( 1/(1-\gamma_D U_D(r_D, t_D)) \) in (15) through (20) can be expanded as power series in dimensionless permeability modulus, and we can get the following equations:

\[
U_D = U_{D0} + \gamma_D U_{D1} + \gamma_D^2 U_{D2} + \cdots,
\]

\[
- \frac{1}{2} \ln \left[ 1 - \gamma_D U_D(r_D, t_D) \right]
\]

\[
= U_D(r_D, t_D) + \frac{1}{2} \gamma_D U_D^2(r_D, t_D) + \cdots,
\]

\[
\frac{1}{1 - \gamma_D U_D(r_D, t_D)}
\]

\[
= 1 + \gamma_D U_D(r_D, t_D) + \gamma_D^2 U_D(r_D, t_D) + \cdots,
\]

Given that the dimensionless permeability modulus \( \gamma_D \) is usually small (much smaller than 1), the zero-order approximate solution can satisfy the requirements of engineering precision, so (15)–(20) become

\[
\frac{\partial^2 U_{D0}}{\partial r_D^2} + \frac{1}{r_D} \frac{\partial U_{D0}}{\partial r_D} = \omega_f \frac{\partial U_{D0}}{\partial t_D} + \omega_m \frac{\partial p_{mD}}{\partial t_D} + \omega_v \frac{\partial p_{vD}}{\partial t_D},
\]

\[
\omega_m \frac{\partial p_{mD}}{\partial t_D} + \lambda_{mf} (p_{mD} - U_{D0}) = 0,
\]

\[
(1 - \omega_f - \omega_m) \frac{\partial p_{vD}}{\partial t_D} + \lambda_{vf} (p_{vD} - U_{D0}) = 0,
\]

\[
\lim_{r_D \to \infty} \frac{\partial U_{D0}}{\partial r_D} \bigg|_{r_D=\infty} = -\tilde{q}_D,
\]

\[
U_{D0} \bigg|_{r_D=0} = 0,
\]

\[
U_{D0} \bigg|_{r_D=0} = p_{mD} \bigg|_{r_D=0} = p_{vD} \bigg|_{r_D=0} = 0.
\]

Equation (22) is the linearized line-sink model in triple-porosity reservoirs.

### 3.4.3. Laplace Transformation.

Take the following Laplace transformation:

\[
\tilde{U}_{D0} = \int_0^{+\infty} U_{D0}(e^{-s t_D}) dt_D,
\]

where \( s \) is the Laplace transformation variable.
Then (22) becomes

\[ \frac{d^2U_{D0}}{dr_D^2} + \frac{1}{r_D} \frac{dU_{D0}}{dr_D} = \omega_i \mu U_{D0} + \omega_m \mu \rho_{mD} + \omega_v \mu \rho_{vD}, \]  

(24)

\[ \omega_m \mu \rho_{mD} + \lambda_{mf} (\rho_{mD} - U_{D0}) = 0, \]  

(25)

\[ \omega_v \mu \rho_{vD} + \lambda_{vf} (\rho_{vD} - U_{D0}) = 0, \]  

(26)

\[ \lim_{\varepsilon \to 0} r_D \frac{dU_{D0}}{dr_D} \bigg|_{r_D = 0} = -\frac{\delta_D}{4}, \]  

(27)

\[ U_{D0} \bigg|_{r_D \to \infty} = 0. \]  

(28)

### 3.4.4. Line-Sink Solution.

Equations (25) and (26) can be rewritten as

\[ p_{mD} = \frac{\lambda_{mf}}{\omega_m \mu + \lambda_{mf}} U_{D0}, \]  

(29)

\[ p_{vD} = \frac{\lambda_{vf}}{\omega_v \mu + \lambda_{vf}} U_{D0}. \]  

Substituting (29) into (24) yields

\[ \frac{d^2U_{D0}}{dr_D^2} + \frac{1}{r_D} \frac{dU_{D0}}{dr_D} = g(u) U_{D0}, \]  

(30)

where

\[ g(u) = \left( \omega_i + \frac{\lambda_{mf}}{\omega_m \mu + \lambda_{mf}} \omega_m + \frac{\lambda_{vf}}{\omega_v \mu + \lambda_{vf}} \omega_v \right) u. \]  

(31)

If we define

\[ g(u) = \left( \omega_i + \frac{\lambda_{mf}}{\omega_m \mu + \lambda_{mf}} \omega_m + \frac{\lambda_{vf}}{\omega_v \mu + \lambda_{vf}} \omega_v \right) u, \]  

then (30) can be expressed as follows:

\[ \frac{d^2U_{D0}}{dr_D^2} + \frac{1}{r_D} \frac{dU_{D0}}{dr_D} = g(u) U_{D0}. \]  

(32)

The general solution of (32) can be easily obtained as follows:

\[ U_{D0} = c_1 K_0 \left( \sqrt{g(u)} r_D \right) + c_2 I_1 \left( \sqrt{g(u)} r_D \right), \]  

(33)

where \( K_0 \) and \( I_0 \) are Bessel functions and \( c_1 \) and \( c_2 \) are unknown coefficients which can be determined by corresponding boundary conditions.

If the line-sink is located at the origin of coordinates (center of the triple-porosity reservoir), then the dimensionless radial distance \( r_D \) in (31) can be calculated by the following equation:

\[ r_D = \sqrt{x_D^2 + y_D^2}. \]  

(34a)

If the line-sink is located at \((x_w, y_w)\) instead, then \( r_D \) is calculated by the following equation:

\[ r_D = \sqrt{(x_D - x_w)^2 + (y_D - y_w)^2}. \]  

(34b)

where

\[ x_D = \frac{x}{L}, \]  

(35)

\[ y_D = \frac{y}{L}, \]  

(36)

\[ x_{wD} = \frac{x_w}{L}, \]  

(37)

\[ y_{wD} = \frac{y_w}{L}. \]  

(38)

Substitution of (33) into the inner boundary condition (27) yields

\[ \lim_{\varepsilon \to 0} \sqrt{g(u)} r_D \left[ -c_1 K_1 \left( \sqrt{g(u)} r_D \right) + c_2 I_1 \left( \sqrt{g(u)} r_D \right) \right]_{r_D = 0} = -\frac{\delta_D}{4}. \]  

(39)

According to the properties of Bessel’s function, which are \( \lim_{x \to 0} x K_1(x) \to 1 \) and \( \lim_{x \to \infty} x I_1(x) \to 0 \), (39) becomes

\[ c_1 = \frac{-\delta_D}{4}. \]  

(40)

Similarly, with the outer boundary condition given in (28) and the properties of Bessel’s function, \( \lim_{x \to \infty} K_0(x) \to 0 \) and \( \lim_{x \to \infty} I_0(x) \to \infty \), the coefficient in (33), \( c_2 \), should satisfy the following equation:

\[ c_2 = 0. \]  

(41)

With (40) and (41), we can get the final form of (33) as follows:

\[ U_{D0} = \frac{\bar{q}}{q} K_0 \left( \sqrt{g(u)} r_D \right). \]  

(42)

Equation (42) is the basic zero-order perturbation solution for a line-sink in a stress-sensitive triple-porosity reservoir. As mentioned above, zero-order perturbation solution is enough to approximate the exact solution of (15) to (20); that is, \( U_D \approx U_{D0} \). With the definition of \( \bar{q}_D \) in Table 1, (42) can be expressed as

\[ U_D = \frac{\bar{q}}{q} K_0 \left( \sqrt{g(u)} r_D \right). \]  

(43)

Equation (43) can be rewritten as

\[ U_D = \frac{\bar{q}}{q} \Omega (x_D, y_D, x_{wD}, y_{wD}), \]  

(44)

where

\[ \Omega (x_D, y_D, x_{wD}, y_{wD}) = K_0 \left( \sqrt{g(u)} r_D \right). \]  

(45)

Equation (44) is the basic line-sink solution for stress-sensitive triple-porosity reservoirs. With the basic line-sink solution and the superposition principle, we can obtain the pressure responses caused by multistage fractured horizontal wells in stress-sensitive triple-porosity reservoirs.
4. Pressure Responses for Multistage Fractured Horizontal Wells in Stress-Sensitive Triple-Porosity Reservoirs

Figure 4 shows the schematic of a horizontal well with multiple (a total of $M$) hydraulic fractures in a stress-sensitive triple-porosity reservoir. The $y$-axis is set to be aligned with the horizontal wellbore. The intersection of the $i$th ($i = 1, 2, \ldots, M$) hydraulic fracture and the $y$-axis is represented by $(0, y_i)$, and the distance between every two adjacent fractures is $\Delta y_j$.

To successfully obtain the pressure responses caused by the multiple fractures with the line-sink solution derived in the above section, it is necessary to discretize the multiple hydraulic fractures. As shown in Figure 4, each hydraulic fracture is divided into $2N$ segments along its length. The coordinate of the midpoint (i.e., discrete node) of the $j$th segment on the $i$th fracture is denoted by $(x_{i,j}, y_{i,j})$, and the coordinates of the two corresponding endpoints are denoted by $(x_{i,j}, y_{i,j})$ and $(x_{i,j+1}, y_{i,j+1})$.

With the discretization scheme shown in Figure 4, the coordinates of endpoints of discrete segments can be calculated by the following equations:

$$
x_{i,j} = -\frac{N-j+1}{N} X_{fiL},
$$

$$
y_{i,j} = y_j, 
1 \leq j \leq N, 
$$

$$
x_{i,j} = \frac{j-N-1}{N} X_{frR},
$$

$$
y_{i,j} = y_j, 
N+1 \leq j \leq 2N+1. 
$$

The coordinates of discrete nodes (midpoint of each segment) can be calculated by the following equations:

$$
x_{i,j} = -\frac{2N-2j+1}{2N} X_{fiL},
$$

$$
y_{i,j} = y_j, 
1 \leq j \leq N, 
$$

$$
x_{i,j} = \frac{2j-N-1}{2N} X_{frR},
$$

$$
y_{i,j} = y_j, 
N+1 \leq j \leq 2N+1. 
$$

Figure 4: Schematic of discrete fracture segments.

The pressure response at $(xD, yD)$ caused by $2N \times M$ segments can be obtained by applying the principle of superposition over all discrete fracture segments:

$$
U_D(xD, yD) = \sum_{i=1}^{M} \sum_{j=1}^{2N} U_{Di,j}(xD, yD). 
$$

(54)

where $X_{fiL}$ is the length of the left wing of $i$th fracture, $m$; $X_{frR}$ is the length of the right wing of $i$th fracture, $m$. In the model presented in this paper, $X_{fiL}$ and $X_{frR}$ can be different and can vary from fracture to fracture.

The distance between $y_j$ and $y_{j-1}$ is

$$
\Delta y_j = y_j - y_{j-1}. 
$$

(48)

It is obvious that the flux strength is different along the fracture length. However, in the same discrete segment (assuming the discrete segment is small enough), the flux strength can be considered as constant. If we use $q_{i,j}$ to represent the flux density per unit length, then, with the superposition principle, the pressure response at $(x_D, y_D)$ in the reservoir caused by the discrete segment $(i, j)$ can be obtained by integrating the basic line-sink along the discrete segment, which is

$$
\bar{U}_{Di,j}(xD, yD) = \frac{q_{i,j}(u)}{q} \int_{x_{i,j}}^{x_{i,j+1}} \Omega(x_D, yD; x_{wD}, y_{wD}) dx_{w}. 
$$

(49)

With the definitions of $x_D$ and $x_{wD}$, that is, (35) and (37), (49) can be changed into

$$
\bar{U}_{Di,j}(xD, yD) = \frac{q_{i,j}(u) L}{q} \int_{x_{Di,j}}^{x_{Di,j+1}} \Omega(x_D, yD; x_{wD}, y_{wD}) dx_{wD}. 
$$

(50)

If we define dimensionless flux density per unit length as

$$
q_{Di,j}(tD) = \frac{q_{i,j}(tD) L}{q}, 
$$

and take Laplace transformation of (51),

$$
\bar{q}_{Di,j}(u) = \frac{q_{i,j}(u) L}{q}. 
$$

(52)

Equation (50) can be rewritten as

$$
\bar{U}_{Di,j}(xD, yD) = \bar{q}_{Di,j} \int_{x_{Di,j}}^{x_{Di,j+1}} \Omega(x_D, yD; x_{wD}, y_{wD}) dx_{wD}. 
$$

(53)

The pressure response at $(x_D, y_D)$ caused by $2N \times M$ segments can be obtained by applying the principle of superposition over all discrete fracture segments:

$$
U_D(xD, yD) = \sum_{i=1}^{M} \sum_{j=1}^{2N} \bar{U}_{Di,j}(xD, yD). 
$$

(54)
Thus, the pressure response at the discrete segment \((\chi, \kappa)\) \((1 \leq \chi \leq M, 1 \leq \kappa \leq 2N)\) can be obtained as follows:

\[
\bar{U}_D \left( x_{D_{\chi \kappa}}, y_{D_{\chi \kappa}} \right) = \sum_{i=1}^{M} \sum_{j=1}^{2N} U_{D_{ij}} \left( x_{D_{\chi \kappa}}, y_{D_{\chi \kappa}} \right). \tag{55}
\]

Since the permeability of hydraulic fractures is always much higher than the original reservoir permeability, the pressure drop in hydraulic fractures is much smaller than the pressure drop caused by oil flow in the reservoir. Thus, the hydraulic fractures can be considered as infinitely conductive, meaning the pressure in hydraulic fractures is equal to the bottom-hole pressure:

\[
\bar{U}_D \left( x_{D_{\chi \kappa}}, y_{D_{\chi \kappa}} \right) = \bar{U}_{\text{wD}}. \tag{56}
\]

Combining (55) and (56), we can get

\[
\sum_{i=1}^{M} \sum_{j=1}^{2N} U_{D_{ij}} \left( x_{D_{\chi \kappa}}, y_{D_{\chi \kappa}} \right) = \bar{U}_{\text{wD}}. \tag{57}
\]

The subscripts \(\chi\) and \(\kappa\) in (57) denote that this equation is written for discrete segment \((\chi, \kappa)\). By writing (57) for all discrete segments, that is, letting \((\chi = 1, 2, \ldots, M, \kappa = 1, 2, \ldots, 2N)\), we can get \(2N \times M\) equations. It should be noted that there are \(2N \times M + 1\) unknowns in these \(2N \times M\) equations, which are \(\bar{U}_{\text{wD}}\) and \(\bar{D}_{D_{ij}}\) \((i = 1, 2, \ldots, M, j = 1, 2, \ldots, 2N)\).

To compose a closed system of equations, the assumption of constant total flow rate can give the following equation:

\[
\sum_{i=1}^{M} \sum_{j=1}^{2N} \left[ q_{i,j} \Delta X_{i,j} \right] = q, \tag{58}
\]

where \(\Delta X_{i,j}\) is the length of the discrete segment \((i, j)\) and can be calculated by

\[
\Delta X_{i,j} = X_{i,j+1} - X_{i,j}. \tag{59}
\]

Taking Laplace transformation of (58), one can get

\[
\sum_{i=1}^{M} \sum_{j=1}^{2N} \left[ \bar{q}_{i,j} \Delta X_{i,j} \right] = \frac{q}{u}. \tag{60}
\]

The dimensionless form of (60) is

\[
\sum_{i=1}^{M} \sum_{j=1}^{2N} \left[ \bar{q}_{D_{ij}} \Delta X_{D_{ij}} \right] = \frac{1}{u}, \tag{61}
\]

where

\[
\Delta X_{D_{ij}} = \frac{\Delta X_{i,j}}{L}. \tag{62}
\]

Equations (57) and (61) represent a system of \((2N \times M + 1)\) linear algebraic equations relating \((2N \times M + 1)\) unknowns, which can be solved by direct methods, such as Gaussian elimination method, Gauss-Jordan reduction method.

\[
\bar{U}_{\text{wD}} \text{calculated by (57) and (61) does not take into account the effects of wellbore storage and skin. According to van Everdingen [26] and Kucuk and Ayestaran [27], the effects of wellbore storage and skin can be incorporated in the calculated bottom-hole pressure response by}
\]

\[
\bar{U}_{\text{wDS}} = \frac{u \bar{U}_{\text{wD}} + S}{u + C_D u^2 (u \bar{U}_{\text{wD}} + S)}, \tag{63}
\]

where \(C_D\) is the dimensionless wellbore storage coefficient and \(S\) is the skin factor defined by the following, respectively:

\[
C_D = \frac{C}{2\pi \left( \phi_1 C_{f1} + \phi_2 C_{f2} + \phi_3 C_{f3} \right) h L^2}, \tag{64}
\]

\[
S = \frac{2\pi k_i h}{q_d u} \Delta P_s, \tag{65}
\]

where \(C\) is the wellbore storage coefficient, \(m^3/\text{Pa}; q_d\) is the sandface flow rate of the multistage fractured horizontal well in the triple-porosity reservoir, \(m^3/\text{s}; \Delta P_s\) is an extra pressure drop near the wellbore, \(\text{Pa}\). \(\bar{U}_{\text{wDS}}\) in (63) is the bottom-hole pressure response obtained in the Laplace domain, and by Stehfest [28] numerical inversion algorithm we can calculate the pressure responses \(U_{\text{wDS}}(t_D)\) in real time domain. Then, with (66), we can obtain the bottom-hole pressure response for multistage fractured horizontal wells in triple-porosity reservoirs incorporating the stress-sensitivity of natural fracture system:

\[
P_{wD}(t_D) = -\frac{1}{\gamma D} \ln \left[ 1 - \gamma B U_{\text{wDS}}(t_D) \right]. \tag{66}
\]

5. Results and Discussion

In this section, a horizontal well with three hydraulic fractures (i.e., \(M = 3\)) in a triple-porosity reservoir is considered, and the model introduced above is applied to investigate the dimensionless pressure responses of this well-reservoir configuration.

5.1. Flow Periods and Effect of Stress-Sensitivity. Figure 5 presents the dimensionless pressure responses and corresponding pressure derivatives of a multistage fractured horizontal well in an infinitely large triple-porosity reservoir with consideration of stress-sensitivity of natural fractures. It can be observed from the figure that as many as ten flow periods can be identified at different time scales. Different flow periods and their corresponding characteristics are explained as follows.

Period 1. It is the early-time wellbore storage period. In this period, both pressure curves and their derivative curves exhibit unit slope on the log-log plots.

Period 2. It is the transition flow period after wellbore storage period. The pressure derivative curves exhibit a “hump,” representing the effect of skin.

Period 3. It is the first linear flow period. This period corresponds to the linear flow in the direction perpendicular
to hydraulic fracture length as illustrated in Figure 6(a). The pressure derivative curves exhibit a straight line with slope equal to “1/2.”

**Period 4.** It is the first pseudoradial flow period. This period can occur when the distances between adjacent fractures are relatively large. Oil flows in the reservoir in a way as shown in Figure 6(b), and pseudoradial flow occurs around each fracture. This period corresponds to a nearly horizontal line with a value of “1/(2M)” in the derivative curve, where M is the number of hydraulic fractures.

**Period 5.** It is the second linear flow period. This period corresponds to linear flow perpendicular to the horizontal wellbore as shown in Figure 6(c). Another straight line with a slope of about “1/2” can be observed in the derivative curve. When the permeability of natural fracture system remains constant during the whole production, corresponding to the no stress-sensitivity case, the slope of the derivative curves during this period is “1/2.” When taking into account the stress-sensitivity of natural fracture system, the corresponding pressure derivative curve slightly deviates from the one-half-slope line and exhibits a slight upward tendency.

**Period 6.** It is the second pseudoradial flow period, corresponding to radial flow in natural fracture system. During this period, multiple hydraulic fractures and the horizontal wellbore behave like an enlarged wellbore. The derivative curves exhibit a horizontal line with an upward tendency depending on the value of dimensionless permeability modulus. In the case that \( \gamma_D = 0 \), the derivative curves are horizontal with a value of 0.5 on the y-axis. With the increase of the value of \( \gamma_D \), the derivative curves turn upward gradually.

**Period 7.** It is the first interporosity flow period. This period reflects mass transfer between vugs and natural fracture system. Due to the oil flowing from vugs to natural fractures, the bottom-hole pressure drops slower and an obvious "dip" can be observed in the derivative curves.

**Period 8.** It is the third pseudoradial flow period, corresponding to compound radial flow in natural fracture system and vugs. Due to the existence of stress-sensitivity of natural fracture system, the pressure derivative curves are no longer horizontal. The position of the derivative curves becomes higher with larger value of \( \gamma_D \).

**Period 9.** It is the second interporosity flow period. This period reflects oil flowing from matrix to natural fracture system. Another characteristic "dip" can be observed in the derivative curves.

**Period 10.** It is the late-time compound pseudoradial flow period. This period reflects compound radial flow in natural fracture system, matrix, and vugs as shown in Figure 6(d). Similarly, the derivative curves exhibit upward tendencies due to the existence of stress-sensitivity of natural fracture system.

**5.2. Effect of Skin Factor.** Figure 7 shows the effect of skin factor on dimensionless pressure curves and corresponding derivative curves. As stated above, the skin factor mainly affects the shape of type curves during the transition period (Period 2) after wellbore storage period. With the increase of the value of skin factor, the position of the “dip” in the derivative curves becomes higher, representing larger pressure drop in the formation.

**5.3. Effect of Storativity Ratio of Natural Fracture System.** Figure 8 shows the effect of storativity ratio of natural fracture system on dimensionless pressure and pressure derivative curves. It is obvious in Figure 8 that when the storativity ratio of matrix (i.e., \( \omega_m \)) and other parameters are kept constant, the storativity ratio of natural fracture system \( \omega_f \) mainly affects the transient pressure dynamics during the first linear flow period, the first pseudoradial flow period, the second linear flow period, second pseudoradial flow period, and the first interporosity flow period. On the one hand, the position of the dimensionless pressure curves becomes higher during the abovementioned flowing periods with the decrease of \( \omega_f \). On the other hand, with the decrease of \( \omega_f \), the position of the pressure derivative curves during the first linear flow period, the first pseudoradial flow, the first porosity flow, and the second linear flow period becomes higher, and the first “dip” in pressure derivative curves becomes wider and deeper.

**5.4. Effect of Storativity Ratio of Matrix.** Figure 9 shows the effect of storativity ratio of matrix on dimensionless pressure and derivative curves. It can be observed that, with fixed \( \omega_f \), the storativity ratio of matrix \( \omega_m \) has primary effect on pressure dynamics during two interporosity flowing periods. With the decrease of the value of \( \omega_m \), the first “dip” in the pressure derivative curves becomes wider and deeper, while the second “dip” in the pressure derivative curves exhibits the opposite trend.

**5.5. Effect of Interporosity Flow Coefficient between Vugs and Natural Fractures.** Figure 10 shows the effect of interporosity flow coefficient between vugs and natural fractures (\( \lambda_{cf} \)) on dimensionless pressure and pressure derivative curves. As expected, \( \lambda_{cf} \) mainly affects the occurrence time of the first
Figure 6: (a) First linear flow period. (b) First pseudoradial flow period. (c) Second linear flow period. (d) Late-time compound pseudoradial flow period.

Figure 7: Type curves with different skin factors.

Figure 8: Type curves with different storativity ratios of natural fracture system.

Figure 9: Type curves with different storativity ratios of matrix.

Figure 10: Type curves with different $\lambda_{vf}$.

interporosity flow period, that is, the appearance time of the first "dip" in pressure derivative curves. The smaller the value of $\lambda_{vf}$ is, the later the first "dip" can be observed in the pressure derivative curves. When $\lambda_{vf}$ decreases to a certain extent, the third pseudoradial flow period (Period 8 in Figure 5) may not be observed in the type curves. In addition, when $\lambda_{vf}$ increases to a certain extent, the second pseudoradial flow period (Period 6 in Figure 5) and even the second linear flow period (Period 5 in Figure 5) may be masked by the following first interporosity flow period.

5.6. Effect of Interporosity Flow Coefficient between Matrix and Natural Fractures. Figure 11 shows the effect of interporosity flow coefficient between matrix and natural fractures ($\lambda_{mf}$) on dimensionless pressure and pressure derivative curves. It can be seen that $\lambda_{mf}$ mainly affects the occurrence time of
the second interporosity flow period, that is, the appearance time of the second "dip" in pressure derivative curves. The smaller the value of $\lambda_{mf}$ is, the later the second "dip" can be observed in the pressure derivative curves. With the increase of $\lambda_{mf}$, the reflection of the third pseudoradial flow period on the derivative curves (Period 8 in Figure 5) may not be observed. When $\lambda_{mf}$ increases to a certain degree, the second "dip" may merge with the first "dip," meaning that simultaneous interporosity mass transfers happen between natural fractures and matrix as well as natural fractures and vugs.

5.7 Effect of Length of Hydraulic Fractures. Figure 12 presents the effect of half-length of hydraulic fractures on type curves. For the convenience of discussion, $X_{flj} = X_{fRI} = X_f$ is assumed here. It can be observed that the length of hydraulic fracture has primary effect on the first linear flow period and the subsequent first pseudoradial flow period. With the increase of fracture length, the first linear flow period last longer with lower position of pressure derivative curves, and the first pseudoradial flow period occurs later with shorter duration. When the half-length of hydraulic fractures continues to increase, the horizontal line in the pressure derivative curves reflecting the first pseudoradial flow period around each fracture will gradually disappear.

5.8 Effect of Hydraulic Fracture Spacing. Figure 13 shows the effect of the distance between adjacent hydraulic fractures. The case discussed in Figure 13 assumes equal fracture spacing for the convenience of discussion. It can be observed that the distance between adjacent hydraulic fractures $\Delta y_i$ mainly affects the first pseudoradial flow period and the subsequent second linear flow period. The larger the distance between adjacent fractures, the longer the duration of the first pseudoradial flow period, and the later the occurrence of the second linear flow period. Another point should be addressed here is that when $\Delta y_i$ increases to a certain degree, the second pseudoradial flow period may not be observed in the type curves; that is, the first interporosity flow period appears after the second linear flow period.

5.9 Flux Distribution. Figure 14 presents the dimensionless flux distribution along hydraulic fractures at a given time based on the calculation results obtained with the model proposed in this paper. In the case presented in Figure 14, three hydraulic fractures with equal half-length and fracture spacing are considered, and each hydraulic fracture is discretized into ten segments. It can be observed that, for the same hydraulic fracture, the flux distribution is symmetrical with respect to the horizontal wellbore, and the flux density at fracture tips is larger than that in the middle of the fracture. In addition, for different hydraulic fractures, it can be found that the flux contribution from hydraulic fracture in the middle (Fracture 3 in Figure 14) is always smaller than that from outer fractures (Fractures 1 and 2 in Figure 14).

6. Conclusion

Based on the mathematical model and discussion in this paper, the following conclusions can be warranted:

(1) A mathematical model is presented for investigating transient pressure dynamics as well as flux distribution of multistage fractured horizontal wells in stress-sensitive triple-porosity reservoirs. The model can better describe fluid flow in naturally fractured reservoirs with multiple types of storage spaces and complex well type.
(2) Semianalytical solution is developed in the Laplace domain by the integral transformation method and discretization of hydraulic fractures. With the semianalytical solution and the numerical inversion algorithm proposed by Stehfest, dimensionless pressure responses and corresponding pressure derivatives as well as flux distribution among all the fractures can be obtained in real time domain. Computation results prove that the model presented in this paper is stable and accurate.

(3) Analysis of transient pressure and derivative responses indicates that as many as ten flow periods can be identified for a multistage fractured horizontal well in triple-porosity reservoirs. Major factors affecting the transient pressure responses include skin factor, storativity ratios of different porous media type, interporosity flow coefficients, and parameters related to the geometry and placement of hydraulic fractures. With different combinations of these parameters, the reflection of some flow periods may be masked in the pressure derivative curves.

(4) Two characteristic "dips" can be observed in the pressure derivative curves for triple-porosity reservoirs, reflecting the mass transfer between natural fracture-vugs and natural fracture-matrix, separately.

(5) The stress-sensitivity of natural fracture system results in larger pressure drop during intermediate and late flowing periods which is reflected by upward tendencies in both dimensionless pressure curves and corresponding derivative curves.

(6) Analysis of flux distribution among multiple hydraulic fractures indicates that the flux contribution from outer fractures is higher, and for a given fracture the flux contribution from fracture tips is higher.

(7) The presented model can be used to interpret pressure signal for fractured horizontal wells in triple-porosity reservoirs and provide some important dynamic parameters for reservoir development.

Appendices

Governing equations for natural fracture system, matrix system, and vug system in triple-porosity reservoirs can be obtained by combining equation of motion, equation of state, and mass conservation equation.

(1) Equation of Motion. Assuming radial flow in triple-porosity reservoirs, the oil flow velocity in natural fracture system is given by

\[ v_f = \frac{k_f}{\mu} \frac{\partial p_f}{\partial r}, \]  

where \( v_f \) is the radial oil velocity in natural fracture system, m/s; \( k_f \) is the permeability of natural fracture system under pressure \( p_f \), m²; \( \mu \) is the oil viscosity, Pa·s; \( p_f \) is the pressure of natural fracture system, Pa; \( r \) is the radial distance, m.

During the production process, the reservoir pressure gradually decreases and the effective stress increases. Consequently, the aperture of natural fractures gradually decreases, resulting in the reduction in the permeability of natural fracture system, which is so-called stress-sensitivity of permeability of natural fracture system. To account for this, a stress-dependent permeability is adopted in the natural fracture flow model.

Following Kikani and Pedrosa [29], the permeability modulus \( \gamma \), which is used to describe the stress-sensitivity of natural fracture system, is defined by

\[ \gamma = \frac{1}{k_f} \frac{d k_f}{d p_f}, \]  

where \( \gamma \) is the permeability modulus, Pa⁻¹.

Equation (A.2) can be further written as

\[ \int_{k_i}^{k_f} \frac{1}{k_f} dk_f = \int_{p_i}^{p_f} \gamma dp_f, \]  

where \( k_i \) is the permeability of natural fracture system under initial condition, m²; \( p_i \) is the reservoir pressure under initial condition, Pa.

Solving (A.3), one can get

\[ k_f = k_i e^{-\gamma(p_f - p_i)}. \]  

Equation (A.4) is one of the most common relationships which are used to describe stress-dependent permeability. This exponential relationship corresponds to Type I rocks discussed by Raghavan and Chin [30].

Substituting (A.4) into (A.1) yields the equation of motion in natural fracture system with consideration of stress-sensitivity effect as follows:

\[ v_f = \frac{k_e e^{-(p_f - p_i)\gamma} \partial p_f}{\mu} \frac{\partial r}{\partial r}. \]  

\[ \text{Figure 14: Dimensionless flux distribution along hydraulic fractures.} \]
(2) Equation of State

(a) Equation of State for Oil. Oil in natural fracture system can be described by the following equation of state:

\[
\rho_t = \rho_0 e^{C_o(p_t - p_0)},
\]  

(A.6a)

where \(\rho_t\) is the oil density in natural fracture system, kg/m\(^3\); \(\rho_0\) is the oil density at the reference pressure \(p_0\), kg/m\(^3\); \(C_o\) is the oil compressibility, Pa\(^{-1}\).

The term \(e^{C_o(p_t - p_0)}\) in (A.6a) can be expanded into Maclaurin series. Considering that \(C_o \ll 1\), the second and higher orders of the expansion can be neglected; thus we can get

\[
\rho_t = \rho_0 \left[ 1 + C_o (p_t - p_0) \right].
\]  

(A.6b)

Similarly, oil in matrix system can be described by the following equation of state:

\[
\rho_m = \rho_0 e^{C_o(p_m - p_0)},
\]  

(A.7a)

or

\[
\rho_m = \rho_0 \left[ 1 + C_o (p_m - p_0) \right],
\]  

(A.7b)

where \(p_m\) is the pressure of matrix system, Pa.

Oil in vug system can be described by the following equation of state:

\[
\rho_v = \rho_0 e^{C_e(p_v - p_0)}
\]  

(A.8a)

or

\[
\rho_v = \rho_0 \left[ 1 + C_e (p_v - p_0) \right],
\]  

(A.8b)

where \(p_v\) is the pressure of vug system, Pa.

(b) Equation of State for Porous Media. The equation of state for natural fracture system can be written as

\[
\phi_t = \phi_{t0} e^{C_o(p_t - p_0)},
\]  

(A.9a)

where \(\phi_t\) is the porosity of natural fracture system, fraction; \(\phi_{t0}\) is the porosity of natural fracture system at the reference pressure \(p_0\), fraction; \(C_o\) is the compressibility of natural fracture system, Pa\(^{-1}\).

Maclaurin series can also be adopted to approximate (A.9a). Considering that \(C_o \ll 1\), the second and higher order terms can be neglected, and one can get

\[
\phi_t = \phi_{t0} \left[ 1 + C_o (p_t - p_0) \right].
\]  

(A.9b)

By following the same procedure, one can get the equation of state for matrix system as follows:

\[
\phi_m = \phi_{m0} e^{C_m(p_m - p_0)}
\]  

(A.10a)

or

\[
\phi_m = \phi_{m0} \left[ 1 + C_m (p_m - p_0) \right],
\]  

(A.10b)

where \(\phi_{m0}\) is the porosity of matrix system at the reference pressure \(p_0\), fraction; \(C_m\) is the compressibility of matrix system, Pa\(^{-1}\).

Similarly, the equation of state for vug system can be described as follows:

\[
\phi_v = \phi_{v0} e^{C_e(p_v - p_0)}
\]  

(A.11a)

or

\[
\phi_v = \phi_{v0} \left[ 1 + C_e (p_v - p_0) \right],
\]  

(A.11b)

where \(\phi_{v0}\) is the porosity of vug system at the reference pressure \(p_0\), fraction; \(C_v\) is the compressibility of matrix system, Pa\(^{-1}\).

(3) Mass Conservation Equation. By applying the mass conservation law on a representative elemental volume in a triple-porosity reservoir, we can get the following equation for natural fracture system:

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \rho_t \phi_t \right) = \frac{\partial}{\partial t} \left( \rho_t \phi_t \right) - q_{c1} - q_{c2}.
\]  

(A.12a)

Equation (A.12a) can also be written in the following equivalent form:

\[
\frac{\partial}{\partial r} \left( r \rho_t \phi_t \right) + \frac{1}{r} \frac{\partial}{\partial r} \left( r \rho_t \phi_t \right) = \frac{\partial}{\partial t} \left( \rho_t \phi_t \right) - q_{c1} - q_{c2}.
\]  

(A.12b)

where \(q_{c1}\) is the mass flow rate between matrix system and fracture system per unit-volume reservoir, kg/(m\(^3\)-s), and it can be expressed by (A.13); \(q_{c2}\) is the mass flow rate between vug system and fracture system per unit-volume reservoir, kg/(m\(^3\)-s), and it can be expressed by (A.14)

\[
q_{c1} = \frac{\alpha_{mf} k_m \rho_0}{\mu} (p_m - p_t),
\]  

(A.13)

\[
q_{c2} = \frac{\alpha_{vd} k_v \rho_0}{\mu} (p_v - p_t),
\]  

(A.14)

where \(\alpha_{mf}\) is the shape factor of matrix blocks, m\(^{-2}\); \(\alpha_{vd}\) is the shape factor of vug system, m\(^{-2}\); \(k_m\) is the permeability of matrix system, m\(^2\); \(k_v\) is the permeability of vug system, m\(^2\).

By using the same method, we can get the following mass conservation equations for matrix system and vug system:

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \rho_m \phi_m \right) = \frac{\partial}{\partial t} \left( \rho_m \phi_m \right) + q_{c1},
\]  

(A.15)

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \rho_v \phi_v \right) = \frac{\partial}{\partial t} \left( \rho_v \phi_v \right) + q_{c2},
\]  

(A.16)

Here, following the assumption adopted in the dual-porosity model proposed by Warren and Root [2], natural fractures are assumed to be oil flowing channels, and matrix and vugs mainly serve as storage space; thus the flowing terms in (A.15) and (A.16) can be reduced to

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \rho_m \phi_m \right) \approx 0,
\]  

(A.17)

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \rho_v \phi_v \right) \approx 0.
\]
With (A.17), (A.15) and (A.16) can be rewritten as
\[
\frac{\partial (\rho_m \phi_m)}{\partial t} + q_{c1} = 0, \quad (A.18)
\]
\[
\frac{\partial (\rho_v \phi_v)}{\partial t} + q_{c2} = 0. \quad (A.19)
\]

Equations (A.12a), (A.12b), (A.18), and (A.19) are mass conservation equations for natural fracture system, matrix system, and vug system in triple-porosity reservoirs, separately.

(4) Governing Equation for Natural Fracture System. Substitution of (A.15) into the mass conservation equation for natural fracture system, that is, (A.12b), yields
\[
\frac{\partial}{\partial t} \left( \rho_i \left( k_i e^{-\left(p_i - p_f^0\right)/\mu} \right) \left( \partial p_i / \partial r \right) \right) + \frac{1}{r} \frac{\partial}{\partial r} \left( k_i e^{-\left(p_i - p_f^0\right)/\mu} \partial p_i / \partial r \right) = \frac{\partial}{\partial t} \left( \rho_i \phi_i \right) - q_{c1} - q_{c2}. \quad (A.20)
\]

With (A.6a), (A.6b), and the transformation formula \( e^{C_i \left(p_i - p_f^0\right)} \partial p_i / \partial r \rightarrow (\partial / \partial r) \left[ e^{C_i \left(p_i - p_f^0\right)} / C_i \right] \), the first term in the left-hand side of (A.20) can be written as
\[
\frac{\partial}{\partial t} \left( \rho_i \left( k_i e^{-\left(p_i - p_f^0\right)/\mu} \right) \left( \partial p_i / \partial r \right) \right) = \rho_i k_i \left[ \frac{1}{\mu} \partial^2 p_i / \partial r^2 + \gamma (\partial p_i / \partial r)^2 \right]. \quad (A.21)
\]

Following the same procedure, the second term in the left-hand side of (A.20) changes into
\[
1 \frac{1}{r} \frac{\partial}{\partial r} \left( k_i e^{-\left(p_i - p_f^0\right)/\mu} \partial p_i / \partial r \right) = \frac{\rho_i k_i}{\mu} \left[ \gamma \partial p_i / \partial r \right] + e^{\gamma \left(p_i - p_f^0\right)} \frac{\partial^2 p_i}{\partial r^2}. \quad (A.22)
\]

With (A.6b) and (A.9b), the product term within the bracket in the right-hand side of (A.20) can be expanded as follows:
\[
\rho_i \phi_i = \rho_i \phi_0 + \rho_i \phi_0 \left( C_i + C_o \right) (p_t - p_0) + \phi_0 \rho_0 C_i C_o \left( p_t - p_0 \right)^2. \quad (A.23a)
\]

Given that both \( C_i \) and \( C_o \) are very small terms, their product will yield a much smaller term which is negligible \( (C_i C_o \approx 0) \), and (A.23a) can be simplified as
\[
\rho_i \phi_i = \rho_i \phi_0 + \rho_i \phi_0 \left( C_i + C_o \right) (p_t - p_0). \quad (A.23b)
\]

Thus the first term in the right-hand side of (A.20) can be written as
\[
\frac{\partial (\rho_i \phi_i)}{\partial t} = \phi_0 \rho_0 C_i \frac{\partial p_0}{\partial t}, \quad (A.24)
\]
where \( C_{ti} \) is the total compressibility of natural fracture system, including the compressibility of oil and natural fractures, and
\[
C_{ti} = C_i + C_o. \quad (A.25)
\]

Substituting (A.13), (A.14), (A.21), (A.22), and (A.24) into (A.20), one can get
\[
\frac{\partial^2 p_t}{\partial r^2} + \frac{1}{r} \frac{\partial p_t}{\partial r} + \gamma \left( \frac{\partial p_t}{\partial r} \right)^2 = e^{-\gamma (p_t - p_f^0)} \left[ \phi_0 \rho_0 C_i \frac{\partial p_0}{\partial t} - \frac{\alpha_{mf} k_m}{k_h} (p_m - p_f) \right]. \quad (A.26a)
\]

After deriving governing equations for matrix system and vug system, (A.26a) can be further written as
\[
\frac{\partial^2 p_t}{\partial r^2} + \frac{1}{r} \frac{\partial p_t}{\partial r} + \gamma \left( \frac{\partial p_t}{\partial r} \right)^2 = e^{-\gamma (p_t - p_f^0)} \left[ \phi_0 \rho_0 C_i \frac{\partial p_0}{\partial t} + \frac{\rho_m C_m \alpha_{mf} k_m}{k_h} \frac{\partial p_m}{\partial t} \right]. \quad (A.26b)
\]

Equation (A.26b) is the final form of governing equation for natural fracture system incorporating the pressure-dependent permeability, that is, (1) in the main body of this paper.

(5) Governing Equation for Matrix System. With (A.7b) and (A.10b), the product of oil density and porosity of matrix system can be written as
\[
\rho_m \phi_m = \rho_{m0} \phi_0 + \rho_{m0} \phi_0 \left( C_m + C_o \right) (p_m - p_0) + \phi_0 \rho_0 \alpha_{mf} k_m \frac{\partial p_m}{\partial t}. \quad (A.27a)
\]

Analogously, because both \( C_m \) and \( C_o \) are very small terms, their product \( \alpha_{mf} k_m \) can be neglected, and (A.27a) can be simplified to obtain
\[
\rho_m \phi_m = \rho_{m0} \phi_0 + \rho_{m0} \phi_0 \left( C_m + C_o \right) (p_m - p_0). \quad (A.27b)
\]

Therefore,
\[
\frac{\partial (\rho_m \phi_m)}{\partial t} = \phi_{m0} \rho_0 C_m \frac{\partial p_m}{\partial t}, \quad (A.28)
\]
where \( C_m \) is the total compressibility of matrix system, including the compressibility of oil and matrix, and
\[
C_m = C_m + C_o. \quad (A.29)
\]

Substitution of (A.13) and (A.28) into the mass conservation equation for matrix system, that is, (A.18), yields
\[
\phi_{m0} C_m \frac{\partial p_m}{\partial t} + \frac{\alpha_{mf} k_m}{\mu} (p_m - p_f) = 0. \quad (A.30)
\]

Equation (A.30) is the final form of governing equation for matrix system in triple-porosity reservoirs, that is, (2) in the main body of this paper.

(6) Governing Equation for Vug System. The derivation of governing equation for vug system is similar to that applied
to matrix system. With (A.8b) and (A.11b), the product of oil density and porosity of vug system can be written as
\[ \rho_v \phi_v = \rho_0 \phi_0 + \rho_0 \phi_0 (C_v + C_o) (p_v - p_o) \]
(A.31a)
\[ + \rho_0 \phi_0 C_v C_o (p_v - p_o)^2. \]
(A.31b)

Given that both \( C_v \) and \( C_o \) are much smaller than 1, their product \( C_v C_o \) is negligible, and (A.31a) reduces to
\[ \rho_v \phi_v = \rho_0 \phi_0 + \rho_0 \phi_0 (C_v + C_o) (p_v - p_o). \]
Therefore,
\[ \frac{\partial (\rho_v \phi_v)}{\partial t} = \rho_0 \phi_0 C_v \frac{\partial p_v}{\partial t}, \]
(A.32)
where \( C_v \) is the total compressibility of vug system, including the compressibility of oil and vug, and
\[ C_v = C_v + C_o. \]
(A.33)

Substituting (A.14) and (A.33) into mass conservation equation for vug system, that is, (A.19), one can get
\[ \phi_v \rho_v \frac{\partial p_v}{\partial t} + \frac{\alpha_v k_v}{\mu} (p_v - p_i) = 0. \]
(A.34)

Equation (A.34) is the final form of governing equation for vug system in triple-porosity reservoirs, that is, (3) in the main body of this paper.

**B. Derivation of Inner Boundary Condition for the Line-Sink**

A vertical line-sink can be treated as the limiting case of a vertical cylinder-sink with radius \( \varepsilon \rightarrow 0 \). The flow rate across the cylinder wall with radius \( \varepsilon \) \( \rightarrow 0 \) can be expressed as
\[ \lim_{\varepsilon \to 0} A \frac{\partial p_i}{\partial r} = \tilde{q}(t) B, \]
(B.1)
where \( A \) is the lateral area of the cylinder-sink, \( m^2 \), which can be calculated by (B.2); \( v_l \) is oil velocity at the cylinder wall, \( m/s \), which can be calculated by (B.3); \( \tilde{q}(t) \) is flow rate of the continuous line-sink under standard condition, \( m^3/s; B \) is the oil formation volume factor, dimensionless:
\[ A |_{r=\varepsilon} = 2\pi \varepsilon h |_{r=\varepsilon}, \]
(B.2)
\[ v_l |_{r=\varepsilon} = \frac{k_i}{\mu} \frac{\partial p_i}{\partial r} |_{r=\varepsilon}. \]
(B.3)

Substitution of (A.4) into (B.3) yields
\[ v_l |_{r=\varepsilon} = \frac{k_i e^{-\gamma(p_v-p_i)}}{\mu} \frac{\partial p_i}{\partial r} |_{r=\varepsilon}. \]
(B.4)

Substituting (B.2) and (B.4) into (B.1), we can get
\[ \lim_{\varepsilon \to 0} e^{-\gamma(p_v-p_i)} \left( \frac{\partial p_i}{\partial r} |_{r=\varepsilon} \right) = \frac{\tilde{q}(t) \mu B}{2\pi k_i h}. \]
(B.5)

Equation (B.5) is the inner boundary condition for a line-sink in triple-porosity reservoirs, that is, (4) in the main body of this paper.

**Nomenclature**

- **B**: Oil formation volume factor, \( m^3/sm^3 \)
- **C**: Wellbore storage coefficient, \( m^3/Pa \)
- **C_D**: Dimensionless wellbore storage coefficient, dimensionless
- **C_o**: Oil compressibility, \( Pa^{-1} \)
- **C_i**: Compressibility of natural fracture system, \( Pa^{-1} \)
- **C_m**: Compressibility of matrix system, \( Pa^{-1} \)
- **C_v**: Compressibility of vug system, \( Pa^{-1} \)
- **C_{mf}**: Total compressibility of matrix system, \( Pa^{-1} \)
- **C_{mv}**: Total compressibility of matrix system, \( Pa^{-1} \)
- **C_{vt}**: Total compressibility of vug system, \( Pa^{-1} \)
- **h**: Reservoir thickness, \( m \)
- **k_i**: Permeability of natural fracture system, \( m^2 \)
- **k_v**: Permeability of natural fracture system under initial condition, \( m^2 \)
- **k_m**: Permeability of matrix system, \( m^2 \)
- **K_0(x)**: Modified Bessel function of the second kind, zero order
- **K_1(x)**: Modified Bessel function of the second kind, first order
- **I_0(x)**: Modified Bessel function of the first kind, zero order
- **L**: Reference length, \( m \)
- **L_h**: Length of horizontal wellbore, \( m \)
- **M**: Total number of hydraulic fractures
- **N**: Number of discretized segments for each fracture
- **p_i**: Pressure of natural fracture system, \( Pa \)
- **P_m**: Pressure of matrix system, \( Pa \)
- **P_v**: Pressure of vug system, \( Pa \)
- **P_{TD}**: Dimensionless pressure of natural fracture system, dimensionless
- **P_{mD}**: Dimensionless pressure of matrix system, dimensionless
- **P_{vD}**: Dimensionless pressure of vug system, dimensionless
- **P_{io}**: Dimensionless pressure of initial reservoir, \( Pa \)
- **P_{p0}**: Reference pressure, \( Pa \)
- **\Delta P_r**: Extra pressure drop caused by skin effect near the wellbore, \( Pa \)
- **\tilde{q}(t)**: Production rate of the line-sink under standard condition, \( m^3/s \)
- **\tilde{q}_D**: Dimensionless production rate of the line-sink under standard condition, dimensionless
- **\tilde{q}_i****: Constant surface production rate of the multistage fractured horizontal well, \( m^3/(s\cdot m) \)
- **\overline{q}_{ij}**: Flux density of the \( j \)th segment in the \( i \)th hydraulic fracture, \( m^3/(s\cdot m) \)
\(q_{Di,j}\): Dimensionless flux density of the \(j\)th segment in the \(i\)th fracture, dimensionless

\(\mathcal{Q}_{Di,j}(u)\): Laplace transformation of \(q_{Di,j}\)

\(q_d\): The sandface flow rate of the multistage fractured horizontal well, \(\text{m}^3/\text{s}\)

\(q_{ci}\): Mass flow rate between matrix and natural fractures per unit-volume reservoir, \(\text{kg}/(\text{m}^3\cdot\text{s})\)

\(q_{cj}\): Mass flow rate between vug system and fracture system per unit-volume reservoir, \(\text{kg}/(\text{m}^3\cdot\text{s})\)

\(r_w\): Radius of horizontal wellbore, \(\text{m}\)

\(r\): Radial distance, \(r = \sqrt{x^2 + y^2}\), \(\text{m}\)

\(r_D\): Dimensionless radial distance, dimensionless

\(S\): Skin factor, dimensionless

\(t\): Time, \(\text{s}\)

\(t_D\): Dimensionless time, dimensionless

\(u\): Variable of Laplace transformation, dimensionless

\(v_j\): Radial velocity for oil flow in natural fracture system, \(\text{m/s}\)

\(x, y\): \(x\)- and \(y\)-coordinates, \(\text{m}\)

\(x_D, y_D\): Dimensionless \(x\)- and \(y\)-coordinates, dimensionless

\(x_w, y_w\): \(x\)- and \(y\)-coordinates of the line-sink, \(\text{m}\)

\(x_{wD}, y_{wD}\): Dimensionless \(x\)- and \(y\)-coordinates of the line-sink, dimensionless

\(X_{i,j}, Y_{i,j}\): \(x\)- and \(y\)-coordinates of the \(i\)th discrete segment in the \(j\)th fracture, \(\text{m}\)

\(X_{Ri}\): Length of the left wing of the \(i\)th fracture, \(\text{m}\)

\(X_{RI}\): Length of the right wing of the \(i\)th fracture, \(\text{m}\)

\(\Delta X_{i,j}\): Length of the discrete segment \((i, j)\), \(\text{m}\)

\(\Delta X_{Di,j}\): Dimensionless length of the discrete segment \((i, j)\), dimensionless

\(y_j\): \(y\)-coordinate of the intersection between the \(i\)th fracture and \(y\)-axis, \(\text{m}\)

\(\Delta y_j\): Distance between \(y_j\) and \(y_{j-1}\), \(\Delta y_j = y_j - y_{j-1}\)

\(\alpha_1\): Shape factor of matrix blocks, \(\text{m}^{-2}\)

\(\alpha_2\): Shape factor of vug system, \(\text{m}^{-2}\)

\(\rho_f\): Oil density in natural fracture system, \(\text{kg}/\text{m}^3\)

\(\rho_0\): Oil density at the reference pressure \(p_0\), \(\text{kg}/\text{m}^3\)

\(\phi_f\): Porosity of natural fracture system, fraction

\(\phi_m\): Porosity of matrix system, fraction

\(\phi_v\): Porosity of vug system, fraction

\(\phi_{f0}\): Porosity of natural fracture system at the reference pressure \(p_0\), fraction

\(\phi_{m0}\): Porosity of matrix system at the reference pressure \(p_0\), fraction

\(\phi_{v0}\): Porosity of vug system at the reference pressure \(p_0\), fraction

\(\omega_f\): Storativity ratio of natural fracture system, dimensionless

\(\omega_m\): Storativity ratio of matrix system, dimensionless

\(\omega_v\): Storativity ratio of vug system, dimensionless

\(\lambda_{mf}\): Interporosity flow coefficient between matrix and natural fractures, dimensionless

\(\lambda_{vf}\): Interporosity flow coefficient between vugs and natural fractures, dimensionless

\(\gamma\): Permeability modulus, \(\text{Pa}^{-1}\)

\(\gamma_0\): Dimensionless permeability modulus, dimensionless

\(\mu\): Oil viscosity, \(\text{Pa}\cdot\text{s}\)

\(\pi\): Circumference ratio, 3.1415926 . . , dimensionless.

Subscript

\(D\): Dimensionless.

Superscript

\(\sim\): Laplace transformation.
