We discuss the completeness of \( \nu \)-generalized metric spaces in the sense of Branciari. We also prove generalizations of Subrahmanyam’s and Caristi’s fixed point theorem.

2. Preliminaries

Throughout this paper we denote by \( \mathbb{N} \) the set of all positive integers and by \( \mathbb{R} \) the set of all real numbers.

In this section, we give some preliminaries.

As we mentioned in Section 1, \( \nu \)-generalized metric spaces do not necessarily have the compatible topology. So we have to define something connected with convergence.

Definition 3. Let \((X, d)\) be a \( \nu \)-generalized metric space.

(i) A sequence \( \{x_n\} \) in \( X \) is said to converge to \( x \) iff \( \lim_{n}d(x, x_n) = 0 \).

(ii) A sequence \( \{x_n\} \) in \( X \) is said to converge only to \( x \) iff \( \lim_{n}d(x, x_n) = 0 \) holds and \( \lim_{n}d(y, x_n) = 0 \) does not hold for \( y \in X \setminus \{x\} \).

(iii) A mapping \( T \) on \( X \) is said to be sequentially continuous iff \( \{Tx_n\} \) converges to \( Tx \) whenever \( \{x_n\} \) converges to \( x \).

(iv) A function \( f \) from \( X \) into \( (-\infty, \infty] \) is said to be sequentially lower semicontinuous iff \( f(x) \leq \liminf_{n} f(x_n) \) whenever \( \{x_n\} \) converges to \( x \).
Definition 4. Let \((X, d)\) be a \(\nu\)-generalized metric space and let \(\kappa \in \mathbb{N}\).

(i) A sequence \(\{x_n\}\) in \(X\) is said to be \(\kappa\)-Cauchy iff
\[
\lim_{n \to \infty} \sup \{d(x_n, x_{n+1+j}) : j = 0, 1, 2, \ldots\} = 0
\]
holds.

(ii) \(X\) is \(\kappa\)-complete iff every \(\kappa\)-Cauchy sequence converges.

Remark 5. We sometimes write “Cauchy” instead of “1-Cauchy” and “complete” instead of “1-complete.”

The following is obvious.

Proposition 6. Let \((X, d)\) be a \(\nu\)-generalized metric space and let \(\kappa, \lambda \in \mathbb{N}\) such that \(\lambda\) is divisible by \(\kappa\). Then, the following hold.

(i) Every \(\kappa\)-Cauchy sequence is \(\lambda\)-Cauchy.

(ii) If \(X\) is \(\lambda\)-complete, then \(X\) is \(\kappa\)-complete.

The following are partially converse to Proposition 6(i).

Proposition 7. Let \((X, d)\) be a \(\nu\)-generalized metric space where \(\nu\) is odd. Let \(\{x_n\}\) be a \(\nu\)-Cauchy sequence such that \(x_n\) are all different. Then, \(\{x_n\}\) is Cauchy.

Proof. In the case where \(\nu = 1\), the conclusion clearly holds. So we assume \(\nu \geq 3\). Fix \(\epsilon > 0\). Then, there exists \(\ell \in \mathbb{N}\) such that
\[
d(x_n, x_{n+1+j}) < \epsilon
\]
for any \(n \in \mathbb{N} \cup \{0\}\) and \(n \in \mathbb{N}\) with \(n \geq \ell\). Fix \(j \in \mathbb{N} \cup \{0\}\) and \(n \in \mathbb{N}\) with \(n \geq \ell\). We first show
\[
d(x_n, x_{n+1+j+2k}) < (kv + 1) \epsilon
\]
for \(k = 0, 1, \ldots, (\nu - 1)/2\). It is obvious that (3) holds when \(k = 0\). We assume that (3) holds for some \(k\) with \(0 \leq k < (\nu - 1)/2\).
Then, we have by (N3)
\[
d(x_n, x_{n+1+j+2(k+1)}) \leq d(x_n, x_{n+1+j+2k}) + d(x_{n+1+j+2k}, x_{n+1+j+(k+1)+2k})
\]
\[
+ \sum_{j=0}^{\nu-1} d(x_j, x_{j+1})
\]
\[
\leq (kv + 1) \epsilon + (v - 1) \epsilon
\]
\[
= (k + 1) v + 1) \epsilon.
\]
Hence, (3) holds when \(k := k + 1\). Therefore, (3) holds for every \(k\), which implies
\[
d(x_n, x_{n+1+j+2k}) < \left(\frac{\nu^2}{2} - \frac{\nu}{2} + 1\right) \epsilon
\]
for any \(j \in \mathbb{N} \cup \{0\}, k = 0, 1, \ldots, (\nu - 1)/2, \) and \(n \in \mathbb{N}\) with \(n \geq \ell\). Using this, we have
\[
d(x_n, x_{n+1+j+2k}) \leq d(x_n, x_{n+1+j+2k}) + d(x_{n+1+j+2k}, x_{n+2+j+2k+\nu - 1})
\]
\[
+ \sum_{j=0}^{\nu-1} d(x_j, x_{j+1})
\]
\[
< 2 \left(\frac{v^2}{2} - \frac{v}{2} + 1\right) \epsilon + (v - 1) \epsilon
\]
\[
= \left(\frac{v^2}{2} + 1\right) \epsilon,
\]
for any \(j \in \mathbb{N} \cup \{0\}, k = 0, 1, \ldots, (\nu - 3)/2, \) and \(n \in \mathbb{N}\) with \(n \geq \ell\). So \(\{x_n\}\) is Cauchy.

Proposition 8. Let \((X, d)\) be a \(\nu\)-generalized metric space where \(\nu\) is even. Let \(\{x_n\}\) be a \(\nu\)-Cauchy sequence such that \(x_n\) are all different. Then, \(\{x_n\}\) is 2-Cauchy.

Proof. Fix \(\epsilon > 0\). Then, there exists \(\ell \in \mathbb{N}\) such that
\[
d(x_n, x_{n+1+j}) < \epsilon
\]
for any \(j \in \mathbb{N} \cup \{0\}, k = 0, 1, \ldots, (\nu - 2)/2, \) and \(n \in \mathbb{N}\) with \(n \geq \ell\). Fix \(j \in \mathbb{N} \cup \{0\}\) and \(n \in \mathbb{N}\) with \(n \geq \ell\). Then, as in the proof of Proposition 7, by induction, we can show
\[
d(x_n, x_{n+1+j+2k}) < (kv + 1) \epsilon
\]
for \(k = 0, 1, \ldots, \nu/2 - 1\). Therefore, we obtain
\[
d(x_n, x_{n+1+j+2k}) < \left(\frac{\nu^2}{2} - \nu + 1\right) \epsilon
\]
for any \(j \in \mathbb{N} \cup \{0\}, \) So \(\{x_n\}\) is 2-Cauchy.

Lemma 9. Let \((X, d)\) be a \(\nu\)-generalized metric space and let \(\{x_n\}\) be a sequence in \(X\) such that \(x_n\) are all different and \(\sum_{n=0}^{\infty} d(x_n, x_{n+1}) < \infty\). Then, \(\{x_n\}\) is \(\nu\)-Cauchy.

Remark 10. Example 1 in [7] tells that there exists some sequence \(\{x_n\}\) in a 2-generalized metric space such that \(\sum_{n=0}^{\infty} d(x_n, x_{n+1}) < \infty\) and \(\{x_n\}\) is not Cauchy.

Proof. Fix \(\epsilon > 0\). Then, there exists \(\ell \in \mathbb{N}\) such that \(\sum_{n=\ell}^{\infty} d(x_n, x_{n+1}) < \epsilon\). Fix \(n \in \mathbb{N}\) with \(n \geq \ell\). We will show
\[
d(x_n, x_{n+j}) \leq \sum_{i=\ell}^{j} d(x_i, x_{i+1})
\]
for any \(j \in \mathbb{N} \cup \{0\}, k = 0, 1, \ldots, (\nu - 1)/2, \) and \(n \in \mathbb{N}\) with \(n \geq \ell\). Using this, we have
by induction. It is obvious that (10) holds for \( j = 0 \). We assume that (10) holds for some \( j \in \mathbb{N} \cup \{0\} \). Then, by (N3), we have

\[
d (x_n, x_{n+1+(j+1)v}) \leq \sum_{i=0}^{n+jv} d (x_i, x_{i+1}) \leq \sum_{i=0}^{n+jv} d (x_i, x_{i+1}) + d (x_{n+jv}, z) \leq d (x_n, z).
\]

Therefore, (10) holds for \( j := j + 1 \). By induction, (10) holds for any \( j \in \mathbb{N} \cup \{0\} \). Hence,

\[
d (x_n, x_{n+1+(j+1)v}) \leq \sum_{i=0}^{n+jv} d (x_i, x_{i+1}) \leq \sum_{i=0}^{\infty} d (x_i, x_{i+1}) < \varepsilon
\]

holds. Therefore, \( \{x_n\} \) is \( \nu \)-Cauchy.

**Lemma 11.** Let \((X, d)\) be a \( \nu \)-generalized metric space and let \( \{x_n\} \) be a sequence in \( X \) such that \( x_n \) are all different, \( \lim_{n \to \infty} d (x_n, x_{n+1}) = 0 \), and \( \{x_n\} \) converges to some \( z \in X \). Then, \( \{x_n\} \) converges only to \( z \in X \).

**Proof.** Arguing by contradiction, we assume that \( \{x_n\} \) converges to \( w \) which differs from \( z \). Since \( x_n \) are all different, \( x_n \neq z \) and \( x_n \neq w \) for sufficiently large \( n \in \mathbb{N} \). By (N3), we have

\[
d (w, z) < \lim_{n \to \infty} d (w, x_n) + \sum_{j=0}^{n+\nu-2} d (x_j, x_{j+1}) + d (x_{n+\nu-1}, z) \leq \sum_{i=0}^{\infty} d (x_i, x_{i+1}) < \varepsilon
\]

where we define \( \sum_{i=0}^{n-1} d (x_i, x_{i+1}) = 0 \). By (N1), we obtain \( w = z \). This is a contradiction.

**Lemma 12.** Let \((X, d)\) be a \( \nu \)-generalized metric space satisfying either of the following:

(i) \( \nu \) is odd and \( X \) is complete;

(ii) \( \nu \) is even and \( X \) is 2-complete.

Let \( \{x_n\} \) be a sequence in \( X \) such that \( x_n \) are all different and \( \sum_{n=1}^{\infty} d (x_n, x_{n+1}) < \infty \). Then, there exists \( z \in X \) such that \( \{x_n\} \) converges only to \( z \).

**Proof.** By Lemma 9, \( \{x_n\} \) is \( \nu \)-Cauchy. By Propositions 7 and 8, the following hold.

(i) If \( \nu \) is odd, then \( \{x_n\} \) is Cauchy.

(ii) If \( \nu \) is even, then \( \{x_n\} \) is 2-Cauchy.

From the assumption on the completeness of \( X \), \( \{x_n\} \) converges to some point \( z \in X \). By Lemma 11, \( \{x_n\} \) converges only to \( z \).

### 3. Fixed Point Theorems

The following is a generalization of Subrahmanyam’s fixed point theorem [8]; see [9–11].

**Theorem 13.** Let \((X, d)\) be as in Lemma 12. Let \( T \) be a sequentially continuous mapping on \( X \). Assume that there exists \( r \in (0, 1) \) satisfying

\[
d (Tx, T^2x) \leq rd (x, Tx)
\]

for all \( x \in X \). Then, for any \( x \in X \), \( \{T^n x\} \) converges only to a fixed point of \( T \).

**Proof.** Define a sequence \( \{u_j\} \) in \( X \) by \( u_j = T^j x \) for \( j \in \mathbb{N} \). We prove the conclusion, dividing the following three cases.

(i) There exists \( n \in \mathbb{N} \) such that \( u_{m+1} = u_n \).

(ii) \( u_{j+1} \neq u_j \) for all \( j \in \mathbb{N} \) and there exist \( m, n \in \mathbb{N} \) such that \( m + 2 \leq n \) and \( u_m = u_n \).

(iii) \( u_1, u_2, \ldots \) are all different.

In the first case, \( u_n \) is a fixed point of \( T \). By (N1), \( \{u_j\} \) converges only to \( u_n \). In the second case, since \( u_{m+1} = u_{n+1} \), we have

\[
d (u_m, u_{m+1}) = d (u_n, u_{n+1}) \leq \cdots \leq r^{n-m} d (u_m, u_{m+1}),
\]

which implies \( d (u_m, u_{m+1}) = 0 \). This is a contradiction. Thus, the second case cannot be possible. In the third case, we have

\[
\sum_{j=1}^{\infty} d (u_j, u_{j+1}) \leq \sum_{j=1}^{\infty} r^{j-1} d (u_1, u_2) = \frac{d (u_1, u_2)}{1 - r} < \infty.
\]

So by Lemma 12, there exists \( z \in X \) such that \( \{u_j\} \) converges only to \( z \). We note that \( \{Tu_j\} = \{u_{j+1}\} \) also converges only to \( z \). Since \( T \) is sequentially continuous, we obtain \( Tz = z \).

A function \( f \) from \( X \) into \((-\infty, +\infty)\) is proper if \( \{x \in X : f(x) \in \mathbb{R}\} \) is nonempty.

The following is a generalization of Caristi’s fixed point theorem [12, 13].

**Theorem 14.** Let \((X, d)\) be as in Lemma 12. Let \( T \) be a mapping on \( X \). Let \( f \) be a proper, sequentially lower semicontinuous function from \( X \) into \((-\infty, +\infty)\) bounded from below. Assume that

\[
f (Tx) + d (x, Tx) \leq f (x)
\]

for all \( x \in X \). Then, \( T \) has a fixed point.
Remark 15. This theorem is connected with Theorem 2 in [14]. See Section 4.

Proof. In the case where \( \nu = 1 \), Theorem 14 becomes the original Caristi fixed point theorem. So we assume \( \nu \geq 2 \).

Arguing by contradiction, we assume that \( T \) does not have a fixed point. Then, we note \( f(Tx) < f(x) \) for every \( x \in X \) with \( f(x) < \infty \).

By induction, we define a sequence \( \{u_j\} \) in \( X \) satisfying the following:

\[
\begin{align*}
    u_{j+1} \neq u_j & \quad \text{for any } j \in \mathbb{N}, \\
    f(u_{j+1}) + d(u_j, u_{j+1}) & \leq f(u_j) < \infty \\
    f(u_{j+1}) & < \inf \{ f(x) : f(x) + d(u_j, x) \leq f(u_j) \} + \frac{1}{j} \quad \text{for any } j \in \mathbb{N}. 
\end{align*}
\]

(18)

Fix \( u_1 \in X \) with \( f(u_1) < \infty \). We assume that \( u_j \) is defined for some \( j \in \mathbb{N} \). Then, we put

\[ S_j = \{ x \in X : f(x) + d(u_j, x) \leq f(u_j) \} \quad \text{for any } j \in \mathbb{N}. \]

(19)

Since \( Tu_j \in S_j \) and \( S_j \) is nonempty, we can define \( u_{j+1} \) satisfying (18). By induction, we have defined \( \{u_j\} \). We note that \( u_j \) are all different because \( f(u_{j+1}) < f(u_j) \) for any \( j \in \mathbb{N} \). Since \( f \) is bounded from below, \( \{f(u_j)\} \) converges. We have

\[
\begin{align*}
    \sum_{j=1}^{\infty} d(u_j, u_{j+1}) & \leq \sum_{j=1}^{\infty} (f(u_j) - f(u_{j+1})) \\
    & = f(u_1) - \lim_{j \to \infty} f(u_j) \\
    & \leq f(u_1) - \inf \{ f(x) : x \in X \} < \infty. 
\end{align*}
\]

(20)

So by Lemma 12, there exists \( z \in X \) such that \( \{u_j\} \) converges only to \( z \). Since \( f \) is sequentially lower semicontinuous, we have

\[
    f(z) \leq \lim_{j \to \infty} f(u_j) \quad \text{and hence } f(z) < f(u_j) \quad \text{for any } j \in \mathbb{N}. 
\]

(21)

We note that \( z \neq u_j \) for any \( j \in \mathbb{N} \). Since \( f(Tz) < f(z) < f(u_j) \), \( Tz \neq u_j \) for any \( j \in \mathbb{N} \). Fix \( m \in \mathbb{N} \) with \( 1/m < f(z) - f(Tz) \). Then, for any \( k \in \mathbb{N} \), we have

\[
\begin{align*}
    f(Tz) + d(u_m, Tz) & \leq f(Tz) + \sum_{j=m}^{m+\nu-2} d(u_j, u_{j+1}) + d(u_{m+\nu-1}, z) \\
    & \leq f(z) + \sum_{j=m}^{m+\nu-2} d(u_j, u_{j+1}) + d(u_{m+\nu-1}, z) \\
    & \leq f(z) + \sum_{j=m}^{m+2\nu-2} d(u_j, u_{j+1}) + d(u_{m+2\nu-1}, z) \\
    & \leq \cdots \leq f(z) + \sum_{j=m}^{m+2\nu-2} d(u_j, u_{j+1}) + d(u_{m+2\nu-1}, z) \\
    & \leq f(u_m) + d(u_{m+2\nu-1}, z).
\end{align*}
\]

(22)

As \( k \) tends to infinity, we obtain \( f(Tz) + d(u_m, Tz) \leq f(u_m) \) and hence \( Tz \in S_m \). Then, we have

\[
\begin{align*}
    f(u_{m+1}) & < \inf \{ f(x) : x \in S_m \} + \frac{1}{m} \\
    & < f(Tz) + f(z) - f(Tz) = f(z).
\end{align*}
\]

(23)

This is a contradiction. \( \square \)

4. Counterexample

Kirk and Shahzad in [7] gave a counterexample to Theorem 2 in [14]. In this section, we give another example.

Lemma 16 (see [4]). Let \( (X, \rho) \) be a bounded metric space and let \( M \) be a real number satisfying

\[
\sup \{ \rho(x, y) : x, y \in X \} \leq M. 
\]

(24)

Let \( A \) and \( B \) be two subsets of \( X \) with \( A \cap B = \emptyset \). Define a function \( d \) from \( X \times X \) into \([0, \infty)\) by

\[
\begin{align*}
    d(x, x) & = 0 \\
    d(x, y) & = \rho(x, y) \quad \text{if } x \in A, \ y \in B \\
    d(x, y) & = M \quad \text{otherwise}.
\end{align*}
\]

(25)

Then, \( (X, d) \) is a 2-generalized metric space.
Remark 17. We assume $X = A \cup B$ in Lemma 4 in [4]. However, we do not use this assumption in the proof.

Example 18. Let $X = \{0\} \cup \{1/n : n \in \mathbb{N}\}$ and define a metric $\rho$ on $X$ as usual. Define two subsets $A$ and $B$ of $X$ by

$$ A = \left\{ \frac{1}{n} : n \in \mathbb{N}, \text{n is odd} \right\}, $$

$$ B = \left\{ \frac{1}{n} : n \in \mathbb{N}, \text{n is even} \right\}. $$

Define a function $d$ from $X \times X$ into $[0, 1]$ as in Lemma 16 with $M = 1$. Define a mapping $T$ on $X$ by

$$ Tx = \begin{cases} 1 & \text{if } x = 0 \\ \frac{1}{n+1} & \text{if } x = \frac{1}{n} \text{ for some } n \in \mathbb{N}. \end{cases} $$

(27)

And define a function $f$ from $X$ into $[0, 2]$ by

$$ f(x) = \begin{cases} 2 & \text{if } x = 0 \\ x & \text{otherwise}. \end{cases} $$

(28)

Then, $(X, d)$ is a complete, 2-generalized metric space, $f$ is sequentially continuous with respect to $d$, and (17) holds. However, $T$ does not have a fixed point.

Proof. By Lemma 16, $(X, d)$ is a 2-generalized metric space. We will show that $X$ is complete. Let $\{x_j\}$ be a Cauchy sequence in $X$. We consider the following three cases.

(i) $\#\{j : x_j = 0\} = \infty$, where $\#\{j : x_j = 0\}$ is the number of the elements of $\{j : x_j = 0\}$.

(ii) $\#\{j : x_j = 1/n\} = \infty$ for some $n \in \mathbb{N}$.

(iii) $\#\{j : x_j = 0\} < \infty$ and $\#\{j : x_j = 1/n\} < \infty$ for any $n \in \mathbb{N}$.

In the first case, since $0 \notin A \cup B$, $x_j = 0$ holds for sufficiently large $j \in \mathbb{N}$. Thus, $\{x_j\}$ converges to 0. In the second case, since

$$ \inf \left\{ d\left(x, \frac{1}{n}\right) : x \in X \setminus \left\{ \frac{1}{n}\right\} \right\} = \frac{1}{n} - \frac{1}{(n+1)} > 0, $$

(29)

$x_n = 1/n$ holds for sufficiently large $j \in \mathbb{N}$. Thus, $\{x_j\}$ converges to $1/n$. We consider the third case. Since $\{x_j\}$ is Cauchy, there exists $\ell_j \in \mathbb{N}$ such that

$$ \sup \left\{ d\left(x_j, x_k\right) : k > j \right\} < 1 $$

(30)

for any $j \in \mathbb{N}$ with $j \geq \ell_j$. We note that $x_{\ell_j} \in A \cup B$ because of the definition of $d$. Without loss of generality, we may assume that $x_{\ell_j} \in A$. There exists $\ell_{\ell_j} \in \mathbb{N}$ such that $\ell_{\ell_j} > \ell_j$ and $x_{\ell_j} \neq x_{\ell_{\ell_j}}$ for $j \in \mathbb{N}$ with $j \geq \ell_j$. Then, $x_{\ell_j} \in B$ clearly holds. Also, there exists $\ell_{\ell_{\ell_j}} \in \mathbb{N}$ such that $\ell_{\ell_{\ell_j}} > \ell_{\ell_j}$ and $x_{\ell_{\ell_j}} \neq x_{\ell_{\ell_{\ell_j}}}$. Then, $x_{\ell_{\ell_j}} \in A$ and $x_{\ell_{\ell_{\ell_j}}} \neq x_{\ell_{\ell_{\ell_{\ell_j}}}}$ clearly hold. We obtain $d(x_{\ell_{\ell_j}}, x_{\ell_{\ell_{\ell_j}}}) < 1$. This is a contradiction. Therefore, the third case cannot be possible. We have shown that $(X, d)$ is complete. We next show that $f$ is sequentially continuous. Let a sequence $\{y_j\}$ in $X$ converge to some $y$. Then, from the definition of $d$, there exists $\ell \in \mathbb{N}$ such that $y_j = y$ for $j \in \mathbb{N}$ with $j \geq \ell$. This fact implies that $f$ is sequentially continuous. For any $x \in X$, $f(Tx) + d(x, Tx) = f(x)$ holds. So (17) is satisfied. However, it is clear that $T$ does not have a fixed point.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
