In this paper, we will introduce the concept of Suzuki type multivalued \((\theta, \mathcal{R})\)-contraction and we will prove some fixed point results in the setting of a metric space equipped with a binary relation. Our results generalize and extend various comparable results in the existing literature. Examples are provided to support the results proved here. As an application of our results, we obtain a homotopy result, proving the existence of a solution for a second-order differential equation and for a first-order fractional differential equation.

1. Introduction and Preliminaries

Let \((X, d)\) be a metric space and \(T : X \rightarrow X\) be a mapping on \(X\). An element \(x \in X\) is called a fixed point of \(T\) if it remains invariant under the action of \(T\); that is, \(x = Tx\). A mapping \(T\) on a metric space \(X\) is said to be a Banach contraction if

\[
d(Tx, Ty) \leq kd(x, y) \tag{1}
\]

holds for all \(x, y \in X\), where \(0 \leq k < 1\). A Banach contraction mapping defined on a complete metric space has a unique fixed point. This result is known as Banach contraction principle. Several authors have extended and generalized Banach contraction principle in different directions.

Jleli and Samet [1] suggested a modification in the contraction condition and introduced a \(\theta\)-contraction mapping. Consistent with [1], the following notations, definitions, and results will be needed in the sequel.

Suppose that

\[
\Omega = \{\theta : (0, \infty) \rightarrow (1, \infty) \text{ satisfy } (\theta_1), (\theta_2) \text{ and } (\theta_3)\} \tag{2}
\]

where

\(\theta\) is nondecreasing;

\((\theta_2)\) for each sequence \(\{t_n\} \subseteq (0, \infty)\), \(\lim_{n \to \infty} \theta(t_n) = 1\) if and only if \(\lim_{n \to \infty} t_n = 0^+\);

\((\theta_3)\) there exists \(r \in (0, 1)\) and \(l \in (0, \infty]\) such that \(\lim_{t \to 0^+} ((\theta(t) - 1)/t^r) = l\).

Example 1. Define \(\eta_i : (0, \infty) \rightarrow (1, \infty)\) for \(i = 1, 2, 3\) by

\[
\eta_1(t) = e^{\sqrt{t}}
\]

\[
\eta_2(t) = 5^{\sqrt{t}} \text{ and } \eta_3(t) = e^{\sqrt{t}}. \tag{3}
\]

Then, \(\eta_1, \eta_2, \eta_3 \in \Omega\).

Let \((X, d)\) be a metric space and \(\theta \in \Omega\). A mapping \(T : X \rightarrow X\) is called a \(\theta\)-contraction if for any \(x, y \in X\), we have

\[
\theta(d(Tx, Ty)) \leq [\theta(d(x, y))]^\alpha \tag{4}
\]

whenever \(d(Tx, Ty) > 0\) and \(0 \leq \alpha < 1\). Jleli and Samet [1] proved the following fixed point theorem in the framework

\[
\sum_{i=1}^{n} a_i x_i = 0
\]

where
of a generalized metric space in the sense of Branciari; i.e., the triangle inequality is replaced by the inequality $d(x, y) \leq d(x, u) + d(u, v) + d(v, y)$, for all pairwise distinct points $x, y, u, v \in X$. Nadler [5] obtained the following multivalued version of Banach contraction principle.

**Theorem 5.** Let $(X, d)$ be a complete generalized metric space and $T : X \to CB(X)$ be a Nadler contraction. Then $T$ has at least one fixed point.

Later on, many researchers have obtained fixed point results for multivalued mappings satisfying generalized contraction type conditions. For example, recently, Hançer et al. [6] proved the following fixed point result for multivalued $\theta$-contractions.

**Theorem 6.** Let $(X, d)$ be a complete metric space and $T : X \to K(X)$ be a multivalued mapping. Suppose that there exist $\theta \in \Theta$ and $0 \leq \alpha < 1$ such that

$$\theta(H(Tx, Ty)) \leq \theta(d(x, y))^\alpha,$$

for any $x, y \in X$, provided that $H(Tx, Ty) > 0$. Then $T$ has at least one fixed point.

Durmaz [7] introduced a new type of generalized multivalued $\theta$-contraction and proved some interesting fixed point results (see also [8]). Kikkawa and Suzuki [9] refined Nadler’s result by proving the following theorem.

**Theorem 7.** Let $\beta : [0, 1) \to (1/2, 1]$ be defined as $\beta(b) = 1/(1 + b)$. Let $(X, d)$ be a complete metric space and $T : X \to CB(X)$. Assume there exists $b \in (0, 1)$ such that

$$\beta(b)d(x, Tx) \leq d(x, y)$$

is equivalent to

$$H(Tx, Ty) \leq bd(x, y).$$

Then $T$ has at least one fixed point.

We denote $\mathbb{R}^+ = [0, \infty)$ and define the following class of mappings, which was considered in [10].

$$\Phi = \left\{ \varphi : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R} \text{ and } \varphi(s, t) \leq \frac{1}{2}s - t \right\}. \tag{11}$$

**Example 8.** Let $\varphi_1 : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}$ be defined by $\varphi(s, t) = v(s) - u(t)$ where $v, s : \mathbb{R}^+ \to \mathbb{R}^+$ are given by $v(s) = s/2$ and $u(t) = t$. Obviously $\varphi_1 \in \Phi$.

**Example 9.** Let $\varphi_2 : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}$ be defined by $\varphi(s, t) = s/2 - (v(s)u(t))$ where $v, s : \mathbb{R}^+ \to \mathbb{R}^+$ are defined by $v(s) = st$ and $u(s) = st + t$ for all $s, t > 0$. Note that $\varphi_2 \in \Phi$.

Many results, dealing with existence of fixed points of mappings satisfying certain contraction type conditions in the framework of complete metric spaces endowed with a partial ordering, have appeared in the last decade. Ran and Reurings [11] proved an analogue of Banach’s fixed point theorem in a metric space endowed with partial ordering and gave an application of their results to solve matrix equations. Alam and Imdad [12] proved another variant of
Banach's fixed point theorem in a metric space equipped with a binary relation which generalized many comparable results, including Ran and Reurings result in [11]. Senapati and Dey [13] proved Banach's fixed point theorem in metric spaces equipped with an arbitrary binary relation using $\omega$-distance. They employed their results to prove the existence of solutions of nonlinear fractional differential equations and fractional thermostat model involving the Caputo fractional derivative. A very nice Ph.D. thesis was written on the same subject; see Dobrian [14].

Let us first recall the following definitions.

**Definition 10.** Let $X$ be a nonempty set and $\mathcal{R}$ be a binary relation defined on $X \times X$. Then, $x$ is $\mathcal{R}$-related to $y$ if and only if $(x, y) \in \mathcal{R}$.

We denote $\mathbb{N}_0 = \{0, 1, 2, \ldots\}$ and $\mathbb{N} = \{1, 2, \ldots\}$.

**Definition 11.** Let $X$ be a nonempty set and $\mathcal{R}$ be a binary relation on $X$. A sequence $\{x_n\} \subset X$ is called $\mathcal{R}$-preserving if
\[
(x_n, x_{n+1}) \in \mathcal{R} \quad \forall n \in \mathbb{N}_0.
\]

**Definition 12.** Let $(X, d)$ be a metric space. A binary relation $\mathcal{R}$ defined on $X$ is called $d$-self closed if whenever $\{x_n\}$ is a $\mathcal{R}$-preserving sequence and $x_0$ converges to $x$, then there exists a subsequence $\{x_{n_k}\}$ of $\{x_n\}$ with either $(x_{n_k}, x) \in \mathcal{R}$ or $(x, x_{n_k}) \in \mathcal{R}$ for all $k \in \mathbb{N}_0$.

**Definition 13.** Let $(X, d)$ be a metric space and $\mathcal{R}$ be a binary relation defined on $X$. A mapping $T : X \to P(X)$ is $\mathcal{R}$-closed if for any $x, y \in X$, $(x, y) \in \mathcal{R}$ implies that $(u, v) \in \mathcal{R}$ for any $u \in Tx$ and $v \in Ty$.

If $T : X \to P(X)$ is a multivalued map, then we set
\[
X(T; \mathcal{R}) = \{x \in X : (x, y) \in \mathcal{R} \text{ for some } y \in Tx\}.
\]

In particular, if $T$ is single-valued, then we denote
\[
X'(T; \mathcal{R}) = \{x \in X : (x, Tx) \in \mathcal{R}\}.
\]

Motivated by the results in [2, 10, 12], we introduce the concept of a Suzuki type multivalued $(\theta, \mathcal{R})$-contraction and present some fixed point results in metric spaces equipped with a binary relation. Our results extend and generalize several results given in [2, 15–19]. We also provide applications of our results to homotopy theory proving the existence of a solution of second-order differential equations and first-order fractional differential equations.

### 2. Multivalued Suzuki Type $(\theta, \mathcal{R})$-Contraction

In this section, we obtain a fixed point result for multivalued Suzuki type $(\theta, \mathcal{R})$-contraction in a metric space equipped with a binary relation $\mathcal{R}$.

Throughout this paper $\theta \in \Theta$ satisfies the following additional property:
\[
(\theta_0) : \theta (\inf A) = \inf_{a \in A} \theta (a)
\]

where $A \subset [0, \infty)$.

We will denote
\[
\Theta^* = \{\theta : [0, \infty) \to [1, \infty) : \theta \text{ satisfies } (\theta_1) - (\theta_6)\}
\]

We start with the following definition.

**Definition 14.** Let $(X, d)$ be a metric space and $\mathcal{R}$ a binary relation on $X$. Assume that $\varphi \in \Phi$ and $\theta \in \Theta^*$. A mapping $T : X \to P(X)$ is a multivalued Suzuki type $(\theta, \mathcal{R})$-contraction if for any $x, y \in X$ with $(x, y) \in \mathcal{R}$
\[
\varphi (d(Tx, Ty)) < 0 \implies \theta (H(Tx, Ty)) \leq \theta (d(x, y))^\alpha \theta (d(Tx, Ty))^\beta \cdot \theta (d(y, Ty)) ^\gamma \theta (d(y, Tx) + d(x, Ty))^\delta,
\]

where $\alpha, \beta, \gamma, \delta \in \mathbb{R}^+$ with $0 \leq \alpha + \beta + \gamma + 2\delta < 1$.

Our first main result is the following.

**Theorem 15.** Let $(X, d)$ be a complete metric space, $\mathcal{R}$ a binary relation on $X$, and $T : X \to CB(X)$ a multivalued Suzuki type $(\theta, \mathcal{R})$-contraction. Suppose that following conditions hold:

1. $X(T; \mathcal{R})$ is nonempty,
2. $T$ is $\mathcal{R}$-closed,
3. $\mathcal{R}$ is $d$-self closed or $T$ has closed graph.

Then $T$ has at least one fixed point.

**Proof.** Since $X(T; \mathcal{R})$ is nonempty, if we choose $x_0 \in X(T; \mathcal{R})$, then there exists some $x_1 \in Tx_0$ such that $(x_0, x_1) \in \mathcal{R}$. If $x_0 = x_1$, the result follows. Assume that $x_0 \neq x_1$. As $(x_0, x_1) \in \mathcal{R}$ and
\[
\varphi (d(x_0, Tx_0), d(x_0, x_1)) \leq \frac{1}{2} d(x_0, Tx_0) - d(x_0, x_1) \leq d(x_0, x_1) - d(x_0, x_1) = 0,
\]

we have
\[
\theta (d(x_1, Tx_1)) \leq \theta (H(Tx_0, Tx_1)) \leq \theta (d(x_1, x_1)) \leq \theta (d(x_0, x_1)) \theta (d(x_0, Tx_0)) ^\alpha \theta (d(x_1, Tx_1)) ^\gamma \theta (d(x_0, Tx_0) + d(x_0, Tx_1)) ^\delta.
\]

Now $d(x_1, Tx_0) = 0$ and $d(x_0, Tx_0) \leq d(x_0, x_1)$ imply that
\[
\theta (d(x_1, Tx_1)) \leq \theta (d(x_0, x_1)) ^{\alpha + \beta} \cdot \theta (d(x_1, Tx_1)) ^\gamma \cdot [\theta (d(x_1, Tx_1)) ^\delta.
\]
Then by \(d(x_0, T_{x_1}) \leq d(x_0, x_1) + d(x_1, T_{x_1})\) and \((\theta_2)\), it follows that
\[
\theta(d(x_0, T_{x_1})) \leq \theta(d(x_0, x_1)) \theta(d(x_1, T_{x_1}))
\]  
(21)
and hence
\[
\theta(d(x_1, T_{x_1})) \leq \left[\theta(d(x_0, x_1))\right]^{\alpha+\delta} \left[\theta(d(x_1, T_{x_1}))\right]^{\gamma+\delta}.
\]  
(22)
Hence, we obtain
\[
\left[\theta(d(x_1, T_{x_1}))\right]^{1-\gamma-\delta} \leq \left[\theta(d(x_0, x_1))\right]^{\alpha+\delta}
\]  
(23)
and, in conclusion, we get that
\[
\theta(d(x_1, T_{x_1})) \leq \left[\theta(d(x_0, x_1))\right]^{(\alpha+\delta)/(1-\gamma-\delta)}.
\]  
(24)
By \((\theta_3)\) we have
\[
\theta(d(x_1, T_{x_1})) = \inf_{y \in T_{x_1}} \theta(d(x_1, y)).
\]  
(25)
Thus,
\[
\inf_{y \in T_{x_1}} \theta(d(x_1, y)) \leq \left[\theta(d(x_0, x_1))\right]^{(\alpha+\delta)/(1-\gamma-\delta)}.
\]  
(26)
We can choose \(x_2 \in T_{x_1}\) such that
\[
\theta(d(x_1, x_2)) \leq \left[\theta(d(x_0, x_1))\right]^{(\alpha+\delta)/(1-\gamma-\delta)}.
\]  
(27)
As \((x_0, x_1) \in \mathcal{R}, x_1 \in T_{x_0}, x_2 \in T_{x_1}\) and \(T\) is \(\mathcal{R}\)-closed, we have that \((x_1, x_2) \in \mathcal{R}\). If \(x_1 = x_2\), the result follows. Assume that \(x_1 \neq x_2\). Also,
\[
\phi(d(x_1, T_{x_1}), d(x_1, x_2)) \\
\leq \frac{1}{2} d(x_1, T_{x_1}) - d(x_1, x_2) \\
< d(x_1, T_{x_1}) - d(x_1, x_2) < 0.
\]  
(28)
Hence,
\[
\theta(d(x_2, T_{x_2})) \leq \theta(H(T_{x_1}, T_{x_2})) \\
\leq \left[\theta(d(x_1, x_2))\right]^{\alpha} \left[\theta(d(x_1, T_{x_1}))\right]^{\beta} \\
\cdot \left[\theta(d(x_2, T_{x_2}))\right]^{\gamma} \\
\cdot \left[\theta(d(x_2, T_{x_1}) + d(x_1, T_{x_2}))\right]^{\delta}.
\]  
(29)
By \(d(x_1, T_{x_2}) \leq d(x_1, x_2) + d(x_2, T_{x_2})\) and \((\theta_2)\), we have
\[
\theta(d(x_1, T_{x_2}) \leq \theta(d(x_1, x_2)) \theta(d(x_2, T_{x_2})).
\]  
(30)
As \(d(x_2, T_{x_1}) = 0\) and \(d(x_1, T_{x_1}) \leq d(x_1, x_2)\), we obtain that
\[
\left[\theta(d(x_2, T_{x_2}))\right]^{1-\gamma-\delta} \leq \left[\theta(d(x_1, x_2))\right]^{\alpha+\beta+\delta}.
\]  
(31)
Hence,
\[
\theta(d(x_2, T_{x_2})) \leq \left[\theta(d(x_1, x_2))\right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}.
\]  
(32)
By \((\theta_4)\), we have
\[
\frac{\theta(d(x_2, T_{x_2}))}{\inf_{y \in T_{x_2}} \theta(d(x_2, y))}.
\]  
(33)
Hence,
\[
\inf_{y \in T_{x_2}} \theta(d(x_2, y)) \leq \left[\theta(d(x_1, x_2))\right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}.
\]  
(34)
We can choose \(x_3 \in T_{x_2}\) such that
\[
\theta(d(x_2, x_3)) \leq \left[\theta(d(x_1, x_2))\right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}.
\]  
(35)
By (27), we get
\[
\theta(d(x_2, x_3)) \leq \left[\theta(d(x_0, x_1))\right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}.
\]  
(36)
Since \((x_1, x_2) \in \mathcal{R}\), and \(T\) is \(\mathcal{R}\)-closed, we have \((x_2, x_3) \in \mathcal{R}\). Continuing this way, we can obtain a sequence \(\{x_n\}\) such that \(x_{n+1} \in T_{x_n}\) and \((x_n)\) is \(\mathcal{R}\)-preserving. Obviously, we have \(d(x_n, T_{x_n}) \leq d(x_n, x_{n+1})\), for all natural numbers \(n \geq 0\). Hence,
\[
\theta(d(x_n, x_{n+1})) \leq \left[\theta(d(x_{n-1}, x_n))\right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}
\]  
(37)
\[
\leq \cdots
\]  
\[
\leq \left[\theta(d(x_0, x_1))\right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}.
\]  
(38)
Letting \(n \to \infty\), we have
\[
\lim_{n \to \infty} \theta(d(x_n, x_{n+1})) = 1.
\]  
(39)
It follows from \((\theta_3)\) that
\[
\lim_{n \to \infty} d(x_n, x_{n+1}) = 0.
\]  
(40)
Now, we show that \(\{x_n\}\) is a Cauchy sequence. If we set \(t_n = d(x_n, x_{n+1})\), then from (37), we obtain
\[
1 < \theta(t_n) \leq \left(\theta(t_{n-1})\right)^{(\alpha+\beta+\delta)/(1-\gamma-\delta)} \leq \cdots
\]  
(41)
\[
\leq \left(\theta(t_1)\right)^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}.
\]  
(42)
Further, from \((\theta_4)\), there exist \(r \in (0, 1)\) and \(l \in (0, \infty)\) such that
\[
\lim_{n \to \infty} \frac{\theta(t_n) - 1}{(t_n)^r} = l.
\]  
(43)
Suppose \(l < \infty\). Let \(B = l/2 > 0\). Then there exists \(n_0 \in \mathbb{N}\) such that for all \(n \geq n_0\), we obtain that
\[
\left|\frac{\theta(t_n) - 1}{(t_n)^r} - l\right| \leq B.
\]  
(44)
Hence, for all \(n \geq n_0\), we have
\[
\frac{\theta(t_n) - 1}{(t_n)^r} - l \geq -B.
\]  
(45)
This implies that
\[ n(t_n)^r \leq A n[\theta(t_n) - 1] \quad \forall n \geq n_0 \text{ and for } A = \frac{1}{B} \quad (44) \]
If \( I = \infty \), then for \( B > 0 \) there exists \( n_0 \) such that for all \( n \geq n_0 \), we have
\[ \frac{\theta(t_n) - 1}{(t_n)^r} \geq B \quad (45) \]
which implies that
\[ n(t_n)^r \leq A n[\theta(t_n) - 1] \quad \forall n \geq n_0, \text{ where } A = \frac{1}{B} \quad (46) \]
Hence, for each case, we obtain that
\[ n(t_n)^r \leq A n[\theta(t_n) - 1] \quad \forall n \geq n_0 \quad (47) \]
Thus, using (40) we have
\[ n(t_n)^r \leq A n \left[ (\theta(t_1))^{(a + \beta + \delta)/(1 - \gamma - \delta)} - 1 \right] \quad \forall n \geq n_0. \quad (48) \]
Therefore,
\[ \lim_{n \to \infty} n(t_n)^r = 0. \quad (49) \]
So, there exists \( n_1 \in \mathbb{N} \) such that for all \( n \geq n_1 \), we have \( 0 < n(t_n)^r < 1 \) which implies that \( t_n < (1/n)^{1/r} \). Let \( m > n > n_1 \in \mathbb{N} \).
\[ d(x_n, x_m) \leq d(x_n, x_{m+1}) + d(x_{m+1}, x_{m+2}) + \cdots \]
\[ + d(x_{m-1}, x_m) = t_{m+1} + t_{m+2} + \cdots + t_m \quad (50) \]
\[ \leq \sum_{i=n}^{\infty} t_i < \sum_{i=n}^{\infty} \left( \frac{1}{i} \right)^{1/r}. \]
By the convergence of the series \( \sum_{i=n}^{\infty} (1/i)^{1/r} \) we get \( d(x_n, x_m) \to 0 \) as \( m, n \to \infty \). Hence, \( [x_i] \) is Cauchy. Since \( (X, d) \) is complete, there exists \( x^* \) in \( X \) such that \( x_n \to x^* \).
We show that \( T \) has a fixed point. Assume on the contrary that \( T \) does not have a fixed point. Then, \( d(x_n, Tx_n) > 0 \) for all natural numbers \( n \geq 0 \). As \( (x_n, x_{m+1}) \in \mathcal{R} \), we have
\[ \frac{1}{2} d(x_n, Tx_n) < d(x_n, x_{m+1}) \leq d(x_n, x_{m+1}), \quad (51) \]
which implies that
\[ \varphi(d(x_n, Tx_n), d(x_n, x_{m+1})) < 0. \quad (52) \]
Furthermore,
\[ d(x_{m+1}, Tx_{m+1}) \leq H(Tx_m, Tx_{m+1}) \quad (53) \]
gives that
\[ \theta(d(x_{m+1}, Tx_{m+1})) \leq \theta(H(Tx_m, Tx_{m+1})) \]
\[ \leq [\theta(d(x_n, x_{m+1}))]^a \cdot [\theta(d(x_n, Tx_n))]^b \]
\[ \cdot [\theta(d(x_n, x_{m+1}))]^c \cdot [\theta(d(x_n, Tx_n) + d(x_{m+1}, Tx_{m+1}))]^d. \quad (54) \]
Thus
\[ [\theta(d(x_n, x_{m+1}))][1 - \gamma - \delta] \leq [\theta(d(x_n, x_{m+1}))]^a + [\theta(d(x_n, Tx_n))]^b \]
which further implies that
\[ \theta(d(x_{m+1}, Tx_{m+1})) \leq [\theta(d(x_n, x_{m+1}))]^{(a + \beta + \delta)/(1 - \gamma - \delta)} \]
\[ < \theta(d(x_n, x_{m+1})). \quad (55) \]
Hence
\[ d(x_{m+1}, Tx_{m+1}) < d(x_n, x_{m+1}), \quad \forall n \in \mathbb{N}. \quad (56) \]
If \( \mathcal{R} \) is \( d \)-self closed, there exists a subsequence \( \{x_{n_k}\} \) of \( \{x_n\} \) such that either \( (x_{n_k}, x^*) \in \mathcal{R} \) or \( (x^*, x_{n_k}) \in \mathcal{R} \). Assume that \( (x_{n_k}, x^*) \in \mathcal{R} \). If \( \phi(d(x_{n_k}, Tx_n), d(x_n, x^*)) \geq 0 \), then we have
\[ \frac{1}{2} d(x_{n_k}, Tx_{n_k}) \geq d(x_{n_k}, x^*). \quad (57) \]
From (57), we obtain that
\[ d(x_{n_k}, x_{n_k+1}) \leq d(x_{n_k}, x^*) + d(x^*, x_{n_k+1}) \]
\[ \leq \frac{1}{2} d(x_{n_k}, Tx_{n_k}) + \frac{1}{2} d(x_{n_k+1}, Tx_{n_k+1}) \]
\[ < \frac{1}{2} d(x_{n_k}, x_{n_k}) + \frac{1}{2} d(x_{n_k+1}, x_{n_k+1}) \]
\[ = d(x_{n_k}, x_{n_k+1}), \quad (59) \]
a contradiction. Hence, \( \phi(d(x_{n_k}, Tx_{n_k}), d(x_{n_k}, x^*)) < 0 \) for all \( k \in \mathbb{N} \).
By our assumption \( x^* \notin Tx^* \). Thus
\[ d(x^*, Tx^*) \leq d(x^*, x_{n_k}) + d(x_{n_k}, Tx^*) \]
\[ \leq d(x^*, x_{n_k}) + H(Tx_{n_k}, Tx^*), \quad (60) \]
which implies that
\[ \theta(d(x^*, Tx^*)) \leq \theta(d(x^*, x_{n_k}))) \theta(H(Tx_{n_k}, Tx^*)). \quad (61) \]
Consequently,
\[ \theta(d(x^*, x_{n_k}))) \theta(H(Tx_{n_k}, Tx^*)) \leq \theta(d(x^*, x_{n_k}))) \]
\[ \cdot \left[ \theta(d(x_{n_k}, x^*)) \right]^a \cdot \left[ \theta(d(x_{n_k}, Tx_{n_k})) \right]^b \]
\[ \cdot \left[ \theta(d(x_{n_k}, x^*)) \right]^c \cdot \left[ \theta(d(x_{n_k}, Tx_{n_k}) + d(x_{n_k}, Tx^*)) \right]^d. \quad (62) \]
Also,
\[ d(x_{n_k}, Tx^*) \leq d(x_{n_k}, x^*) + d(x^*, Tx^*). \quad (63) \]
From (61), it follows that
\[
\theta (d(x^*, Tx^*)) \leq \left[ \theta (d(x^*, x_{n_0})) \right]^{1+\alpha+\delta} \\
\cdot \left[ \theta (d(x^*, Tx^*)) \right]^{\beta+\gamma} \\
\cdot \left[ \theta (d(x_{n_1}, x_{n_1})) \right]^\delta.
\]
(64)

Letting \( k \rightarrow \infty \) in (64) we obtain that
\[
\theta (d(x^*, Tx^*)) \leq \left[ \theta (d(x^*, Tx^*)) \right]^{\beta+\gamma} \\
< \theta (d(x^*, Tx^*)),
\]
(65)
a contradiction. Hence, \( x^* \in T x^* \).

If \( T \) has closed graph, since \( x_{n+1} \in T x_n \) for each \( n \in \mathbb{N}_0 \) and \( \lim_{n \rightarrow \infty} x_n = x^* \), we get that \( x^* \in T x^* \).

If we take \( \beta, \gamma, \delta = 0 \) in Theorem 15, we obtain a Suzuki type generalization of the result in [6] in the framework of a complete metric space equipped with a binary relation \( R \).

**Corollary 16.** Let \((X, d)\) be a complete metric space, \( R \) a binary relation on \( X \) and \( T : X \rightarrow CB(X) \). Assume that \( \varphi \in \Phi \) and \( \theta \in \Theta^* \). Suppose that there exists \( 0 \leq \alpha < 1 \) such that for any \( x, y \in X \) with \((x, y) \in R \),
\[
\varphi (d(x, Tx), d(x, y)) < 0
\]
(66)
implies that
\[
\theta (H(Tx, Ty)) \leq \left( \theta (d(x, y)) \right)^\alpha.
\]
(67)
If conditions (1)-(3) in Theorem 15 are satisfied, then \( T \) has a fixed point.

If we take \( \theta(t) = e^{\sqrt{t}} \), Theorem 15, then we have the following multivalued extension of Cirić result in [16].

**Corollary 17.** Let \((X, d)\) be a complete metric space, \( R \) a binary relation on \( X \), and \( T : X \rightarrow CB(X) \). Suppose that \( \varphi \in \Phi \) and there exist \( \alpha, \beta, \gamma, \delta \in \mathbb{R}^+ \) with \( 0 \leq \alpha+\beta+\gamma+2\delta < 1 \), such that for any \( x, y \in X \) with \((x, y) \in R \),
\[
\varphi (d(x, Tx), d(x, y)) < 0
\]
(68)
implies that
\[
\sqrt{H(Tx, Ty)} \leq \alpha \sqrt{d(x, y)} + \beta \sqrt{d(x, Tx)} \\
+ \gamma \sqrt{d(y, Ty)} \\
+ \delta \sqrt{d(x, Ty) + d(y, Tx)}.
\]
(69)
Assume that conditions (1)-(3) in Theorem 15 are satisfied. Then \( T \) has a fixed point.

**Remark 18.** Note that the conclusion of Corollary 17 can be written as
\[
H(Tx, Ty) \\
\leq \alpha^2 d(x, y) + \beta^2 d(x, Tx) + \gamma^2 d(y, Ty) \\
+ \delta^2 [d(x, Ty) + d(Tx, y)] \\
+ 2\alpha \beta \sqrt{d(x, y) d(x, Tx)} \\
+ 2\alpha \gamma \sqrt{d(x, y) d(y, Ty)} \\
+ 2\alpha \delta \sqrt{d(x, Ty) + d(Tx, y)} \\
+ 2\beta \gamma \sqrt{d(x, Tx) d(y, Ty)} \\
+ 2\beta \delta \sqrt{d(x, Ty) (d(x, Ty) + d(y, Tx))} \\
+ 2\gamma \delta \sqrt{d(y, Ty) (d(x, Ty) + d(y, Tx))}
\]
(70)
Assume that conditions (1)-(3) in Theorem 15 are satisfied, then \( T \) has a fixed point.

Notice that if we take \( \alpha, \beta, \gamma = 0 \) in Theorem 15, using Remark 18, we obtain the following multivalued Suzuki type generalization of Chatterjea’s result in [15].

**Corollary 19.** Let \((X, d)\) be a complete metric space, \( R \) a binary relation on \( X \), and \( T : X \rightarrow CB(X) \). Suppose that \( \varphi \in \Phi \) and there exists \( \delta \in [0, 1/2) \) such that for any \( x, y \in X \) with \((x, y) \in R \),
\[
\varphi (d(x, Tx), d(x, y)) < 0
\]
(71)
implies that
\[
H(Tx, Ty) \leq \delta^2 [d(x, Ty) + d(y, Tx)]
\]
(72)
Assume that conditions (1)-(3) in Theorem 15 are satisfied, then \( T \) has a fixed point.

If we take \( \alpha = \delta = 0 \) in Theorem 15, using Remark 18, we obtain the following multivalued Kannan type result in [17].

**Corollary 20.** Let \((X, d)\) be a complete metric space, \( R \) a binary relation on \( X \), and \( T : X \rightarrow CB(X) \). Suppose that \( \varphi \in \Phi \) and there exist \( \beta, \gamma \in \mathbb{R}^+ \) with \( 0 \leq \beta + \gamma < 1 \) such that for any \( x, y \in X \) with \((x, y) \in R \),
\[
\varphi (d(x, Tx), d(x, y)) < 0
\]
(73)
implies that
\[
H(Tx, Ty) \leq \beta^2 d(x, Tx) + \gamma^2 d(y, Ty) \\
+ 2\beta \gamma \sqrt{d(x, Tx) d(y, Ty)}.
\]
(74)
Assume that conditions (1)-(3) in Theorem 15 are satisfied. Then \( T \) has a fixed point.

Taking \( \delta = 0 \) in Theorem 15, we have a multivalued extension and generalization of Reich’s result in [20].
Corollary 21. Let \((X,d)\) be a complete metric space, \(\mathcal{R}\) a binary relation on \(X\), and \(T : X \rightarrow CB(X)\). Suppose that \(\varphi \in \Phi\) and there exist \(\alpha, \beta, \gamma \in \mathbb{R}_+^*\) with \(0 \leq \alpha + \beta + \gamma < 1\), such that for any \(x, y \in X\) with \((x, y) \in \mathcal{R}\), the following implication is true

\[
\varphi(d(x,Tx), d(x,y)) < 0
\]

implying that

\[
\begin{align*}
H(Tx,Ty) & \leq \alpha^2 d(x,y) + \beta^2 d(x,Tx) + \gamma^2 d(y,Ty) \\
& + 2\alpha\beta \sqrt{d(x,y)d(x,Tx)} \\
& + 2\alpha \gamma \sqrt{d(x,y)d(y,Ty)}
\end{align*}
\]

Assume that conditions (1)-(3) in Theorem 15 are satisfied. Then \(T\) has a fixed point.

Similarly, if we take \(\theta(t) = e^\frac{\alpha t}{2}\), then we obtain the following corollary.

Corollary 22. Let \((X,d)\) be a complete metric space, \(\mathcal{R}\) a binary relation on \(X\), and \(T : X \rightarrow CB(X)\). Suppose that \(\varphi \in \Phi\) and there exist \(\alpha, \beta, \gamma \in \mathbb{R}_+^*\) with \(0 \leq \alpha + \beta + \gamma + 2\delta < 1\), such that for any \(x, y \in X\) with \((x, y) \in \mathcal{R}\),

\[
\varphi(d(x,Tx), d(x,y)) < 0
\]

implies that

\[
\begin{align*}
\sqrt{H(Tx,Ty)} & \leq \alpha \sqrt{d(x,y)} + \beta \sqrt{d(x,Tx)} \\
& + \gamma \sqrt{d(y,Ty)} \\
& + \delta (d(x,Tx) + d(y,Ty))
\end{align*}
\]

Assume that conditions (1)-(3) in Theorem 15 are satisfied. Then \(T\) has a fixed point.

We now give an example of a multivalued Suzuki type \((\theta, \mathcal{R})\)-contraction which is neither a multivalued Banach contraction nor a multivalued \((\theta, \mathcal{R})\)-contraction.

Example 23. Let \(X = \{x_1, x_2, x_3\}\). Define the binary relation on \(X\) as follows:

\[
\mathcal{R} = \{(x_1, x_2), (x_1, x_3), (x_2, x_1), (x_2, x_3), (x_3, x_2), (x_3, x_3)\}
\]

Let \(d : X \times X \rightarrow \mathbb{R}_+^*\) be defined by

\[
\begin{align*}
d(x_1, x_2) &= 4, \\
d(x_2, x_3) &= 1, \\
d(x_1, x_3) &= 3
\end{align*}
\]

and \(d(x,y) = d(y,x), d(x,x) = 0\), for \(x, y \in X\).

Define the mapping \(T : X \rightarrow CB(X)\) by

\[
Tx = \begin{cases} 
\{x_1, x_2\}, & \text{whenever } x \in \{x_1, x_2\} \\
\{x_1\}, & \text{whenever } x = x_3.
\end{cases}
\]

Clearly, \(T\) is \(\mathcal{R}\)-closed and \(X(T; \mathcal{R})\) is nonempty. Indeed, if \(x = x_1\), then \(x_1, x_2 \in \mathcal{R}\). Take an \(\mathcal{R}\)-preserving sequence \(\{x_n\}\) such that \(\{x_n\}\) converges to \(x\) and \((x_n, x_{n+1}) \in \mathcal{R}\) for all \(n \in \mathbb{N}_0\). Then, \((x_n, x_{n+1}) \in \{(x_1, x_1), (x_1, x_2), (x_2, x_1), (x_2, x_2), (x_2, x_3), (x_2, x_3), (x_3, x_2), (x_3, x_3)\}\) for all \(n \in \mathbb{N}_0\). Thus, \(\{x_n\} \subset \{x_1, x_2\} \text{ or } \{x_2, x_3\}\). Since both \(\{x_1, x_2\}\) and \(\{x_2, x_3\}\) are closed, either \(\{x_n, x\} \in \mathcal{R}\) or \(x_n \in \mathcal{R}\).

Let \(\varphi(r, s) = r/2 - s\) and \(\theta(t) = e^\frac{t}{\alpha}\). We consider following cases:

1. If \((x,y) = (x_3, x_2)\), then \((1/2)d(x_3, x_2) - d(x_3, x_2) = 3/2 - 1 > 0\).
2. If \((x,y) = (x_1, x_2)\), then clearly \((1/2)d(x_2, x_2) - d(x_2, x_2) = 0\).

Thus, we have \(\theta(H(Tx,Ty)) = \theta(d(x_3, x_2)) = 0\) for any \(0 < k < 1\). Thus \(T\) is not a Nadler’s contraction. Also,

\[
\theta(H(Tx,Ty)) = e^\frac{t}{\alpha} > (e^\frac{t}{\alpha})^k = (\theta(d(x_3, x_2)))^k
\]

for any \(0 < k < 1\). Thus, \(T\) is not multivalued \((\theta, \mathcal{R})\)-contraction. If \(T : X \rightarrow X\) is a single-valued map, then we have the following result.

Theorem 24. Let \((X,d)\) be a complete metric space, \(\mathcal{R}\) a binary relation on \(X\), and \(T : X \rightarrow X\). Suppose that \(\varphi \in \Phi\), \(\theta \in \Theta\) and there exist \(\alpha, \beta, \gamma, \delta \in \mathbb{R}_+^*\) with \(0 \leq \alpha + \beta + \gamma + 2\delta < 1\), such that for any \(x, y \in X\) with \((x, y) \in \mathcal{R}\),

\[
\varphi(d(x,Tx), d(x,y)) < 0
\]

implies that

\[
\begin{align*}
\theta(d(Tx,Ty)) & \leq \theta(d(x,y))^\alpha \theta(d(x,Tx))^\beta \\
& \cdot \theta(d(y,Ty))^\gamma \\
& \cdot \theta(d(x,Ty) + d(y,Tx))^\delta.
\end{align*}
\]

In addition, assume that the following conditions also hold:
Consider the following cases:

(1) We obtain a Suzuki type generalization of θ-contraction result in [2] in the setup of metric spaces endowed with binary relation. If θ(t) = e^{\frac{t}{2}} , the above theorem also generalizes the result in [16].

(2) If θ(t) = e^{\frac{t}{2}} , β, γ, δ = 0, and α < 1, we obtain a Suzuki type result in the setup of metric spaces endowed with binary relation (see [19]).

(3) If θ(t) = e^{\frac{t}{2}} , α, β, γ = 0, and δ < 1/2, we obtain a Suzuki type version of Chatterjea result [15] in the setup of metric spaces endowed with binary relation.

(4) If θ(t) = e^{\frac{t}{2}} , α, δ = 0, and β + γ < 1, we obtain a Suzuki type result for generalized Kannan mappings [17] in the setup of metric spaces endowed with binary relation.

Example 26. Let X = [0, 3] ∪ [5, 9] be the usual metric space with binary relation defined as follows:

\[ \mathcal{R} = \{(1, 1), (1, 3), (3, 1), (3, 3), (1, 5), (5, 5), (5, 9), (9, 5), (9, 9)\}. \] (87)

Define the mapping \( T: X \rightarrow X \) by

\[ T(x) = \begin{cases} 2x + 3, & \text{whenever } 1 \leq x \leq 3 \\ 9, & \text{whenever } 5 \leq x \leq 9. \end{cases} \] (88)

Let \( \varphi(s, t) = (1/2)s - t \) and \( \theta(t) = 5^{\frac{t}{2}} \). Note that \( T \) is not a \((\theta, \mathcal{R})\)-contraction because

\[ \theta(d(T(1, T3)) = \theta(d(1, 5)) = 5^{\frac{5}{2}} > (\theta(d(1, 5)))^k \]

\[ = \left(5^{\frac{5}{2}}\right)^k. \] (89)

Consider the following cases:

(1) If \((x, y) \in \{(1, 1), (1, 3), (3, 1), (3, 3)\}\), then \((1/2)d(x, T) - d(x, y) < 0\) does not hold.

(2) If \((x, y) \in \{(5, 5), (5, 9), (9, 5), (9, 9)\}\), then clearly \( T \) is a Suzuki type \((\theta, \mathcal{R})\)-contraction.

(3) If \((x, y) = (1, 5)\), then we have

\[ \frac{1}{2}d(1, T1) - d(1, 5) = \frac{1}{2}d(1, 5) - (d(1, 5)) < 0 \] (90)

For α, β, γ = 0.1 and \( \delta = 0.4 \), we obtain that

\[ \theta(d(T1, T5)) < (\theta(d(1, 5)))^g \theta(d(1, T1))\]

\[ \cdot (\theta(d(5, T5)))^h \cdot (\theta(d(1, T1)) + d(5, T1))^g \]

which implies that

\[ 5^{\frac{5}{2}} < \left(5^{\frac{5}{2}}\right)^{0.1} \left(5^{\frac{5}{2}}\right)^{0.1} \left(5^{\frac{5}{2}}\right)^{0.1} \left(5^{\frac{5}{2}}\right)^{0.4}. \] (92)

Clearly, \( T \) is \( \mathcal{R} \)-closed and \( X'(T; \mathcal{R}) \) is nonempty, since \((5, 9) \in \mathcal{R} \). Take an \( \mathcal{R} \)-preserving sequence \( \{x_n\} \) such that \( \{x_n\} \) converges to \( x \) and we have \( (x_n, x_{n+1}) \in \mathcal{R} \) for all \( n \in \mathbb{N} \). Note that \( (x_n, x_{n+1}) \notin \{(1, 5)\} \). Then, \( (x_n, x_{n+1}) \in \{(1, 1), (1, 3), (3, 1), (3, 3), (5, 5), (5, 9), (9, 5), (9, 9)\} \) for \( n \in \mathbb{N} \). Hence, \( \{x_n\} \) is a subset of \( \{1, 3, 5, 9\} \) or \( \{5, 9\} \). Since all of these sets are closed, either \( (x_n, x) \in \mathcal{R} \) or \((x, x_n) \in \mathcal{R} \). Thus all the conditions of Theorem 24 are satisfied. Moreover, \( x = 9 \) is a fixed point of \( T \).

3. Application to Homotopy Results

In this section, as an application of our above fixed point result for Suzuki type \((\theta, \mathcal{R})\)-contractions, we obtain a homotopy result for this class of multivalued mappings. For the beginning, we give a local fixed point result for multivalued Suzuki type \((\theta, \mathcal{R})\)-contraction. Let \( B(x_0, r) \) be an open ball and \( \overline{B(x_0, r)} \) the closure of \( B(x_0, r) \).

Theorem 27. Let \((X, d)\) be a complete metric space, \( \mathcal{R} \) a binary relation on \( X \), \( x_0 \in X \) and \( r > 0 \). Suppose that \( T: \overline{B(x_0, r)} \rightarrow CB(X) \) be a multivalued Suzuki type \((\theta, \mathcal{R})\)-contraction with \( \theta(d(x_0, Tx_0)) < (\theta(r))^{1-k} \) where \( 0 < k < 1 \). Assume that the following conditions are also satisfied:

(1) \( x_0 \in X(T; \mathcal{R}) \),

(2) \( T \) is \( \mathcal{R} \)-closed,

(3) \( T \) has closed graph or \( \mathcal{R} \) is \( d \)-self closed.

Then \( T \) has a fixed point in \( \overline{B(x_0, r)} \).

Proof. Since \( x_0 \in X(T; \mathcal{R}) \), there exists \( x_1 \in Tx_0 \) such that \( (x_0, x_1) \in \mathcal{R} \). If \( x_0 = x_1 \), the result follows. Assume that \( x_0 \neq x_1 \). Let \( 0 < s < r \) be such that \( B(x_0, s) \subset B(x_0, r) \) and \( \theta(d(x_0, Tx_0)) < (\theta(s))^{1-k} < (\theta(r))^{1-k} \). Clearly, \( d(x_1, Tx_1) \leq H(Tx_0, Tx_1) \). Now

\[ \varphi(d(x_0, Tx_0), d(x_0, x_1)) \]

\[ \leq \frac{1}{2}d(x_0, Tx_0) - d(x_0, x_1) \] (93)

\[ < d(x_0, Tx_0) - d(x_0, x_1) < 0 \]
Thus, we have
\[ \theta(d(x_1, T x_1)) \leq \left[ \theta(d(x_0, x_1)) \right]^\alpha \left[ \theta(d(T x_0, x_1)) \right]^\beta \cdot \left[ \theta(d(x_1, T x_1)) \right]^\gamma \cdot \left[ \theta(d(x_0, T x_0)) \right]^\delta. \] (94)

Hence
\[ \left[ \theta(d(x_1, T x_1)) \right]^{1-\gamma-\delta} \leq \left[ \theta(d(x_0, x_1)) \right]^{\alpha+\beta+\delta}. \] (96)

which implies that
\[ \theta(d(x_1, T x_1)) \leq \left[ \theta(d(x_0, x_1)) \right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}. \] (97)

By the condition \((\theta_3)\), we get
\[ \inf_{y \in T x_1} \theta(d(x_1, y)) \leq \left[ \theta(d(x_0, x_1)) \right]^{(\alpha+\beta+\delta)/(1-\gamma-\delta)}. \] (98)

We may now choose \( x_2 \in T x_1 \) such that \((x_1, x_2) \in \mathcal{R} \) and
\[ \theta(d(x_1, x_2)) \leq \left[ \theta(d(x_0, x_1)) \right]^k \] (99)

where \( k = (\alpha + \beta + \delta)/(1 - \gamma - \delta) < 1 \). Furthermore,
\[ \theta(d(x_1, x_2)) \leq \left[ \theta(d(x_0, x_1)) \right]^k < (\theta(s))^{1-k^k}. \] (100)

Note that
\[ \theta(d(x_0, x_2)) \leq \theta(d(x_0, x_1)) \theta(d(x_1, x_2)) < (\theta(s))^{1-k^k} < (\theta(s))^{1-k^2} < \theta(s). \] (101)

Thus \( x_2 \in B(x_0, s) \) as \( d(x_0, x_2) < s \). Continuing this way, we obtain a sequence \( \{x_n\} \) with following properties:

1. \( x_n \in B(x_0, s) \),
2. \( (x_{n}, x_{n+1}) \in \mathcal{R} \),
3. \( x_{n+1} \in T x_n \) \( \forall n \in \mathbb{N}_0 \),
4. \( \theta(d(x_{n}, x_{n+1})) < (\theta(s))^{k^{1-k^k}} \).

By similar arguments to those in the proof of Theorem 15, we obtain that \( \{x_n\} \) is a Cauchy sequence which converges to \( u \in B(x_0, r) \) and \( u \in Tu \).

Now we present the following homotopy result.

**Theorem 28.** Let \((X, d)\) be a complete metric space, \( U \) an open set of \( X \), \( \mathcal{R} \) a \( d \)-self closed binary relation on \( X \) and \( \Lambda : \overline{U} \times [0,1] \rightarrow P(X) \) be a multivalued mapping with closed values. Suppose that for each \( t \in [0,1] \), \( \Lambda(\cdot, t) : \overline{U} \rightarrow CB(X) \) satisfies the conditions (1)-(2) in Theorem 27. Assume that the following conditions are also satisfied:

1. \( x \notin \Lambda(x, t) \), for each \( x \in \partial U \) and each \( t \in [0,1] \);
2. \( \Lambda(\cdot, t) : \overline{U} \rightarrow CB(X) \) is a multivalued Suzuki type \((\theta, \mathcal{R})\)-contraction with closed graph, for each \( t \in [0,1] \);
3. there exists a continuous increasing function \( \eta : [0,1] \rightarrow \mathbb{R} \) such that
\[ \theta(H(\Lambda(x, t), \Lambda(x, s)) \leq \theta(\eta(t) - \eta(s)) \] (102)
for all \( t, s \in [0,1] \) and each \( x \in \overline{U} \).

Then \( \Lambda(\cdot, 0) \) has a fixed point if and only if \( \Lambda(\cdot, 1) \) has a fixed point.

**Proof.** Suppose that \( \Lambda(\cdot, 0) \) has a fixed point \( z \), then by (1) \( z \in U \). Define
\[ Q = \{ (x, t) \in U \times [0,1] : x \in \Lambda(x, t) \} \] (103)
As \( (z, 0) \in Q \), so \( Q \neq \emptyset \). Define partial order on \( Q \) by
\[ (x, t) \preceq (y, s) \] (104)
and
\[ \theta(d(x, y)) \leq \theta(\eta(t) - \eta(s))^{2/(1-k)}, \]
where \( k = \frac{\alpha + \beta + \delta}{1 - \gamma - \delta} \). (105)

Let \( A \) be a totally ordered set in \( Q \) and \( t_* = \sup \{ t : (x, t) \in A \} \). Consider a sequence \( \{(x_n, t_n)\} \) in \( A \) such that \( (x_n, t_n) \preceq (x_{n+1}, t_{n+1}) \) and \( t_n \rightarrow t_* \) as \( n \rightarrow \infty \). Then, we have
\[ \theta(d(x_m, x_n)) \leq \theta(\eta(t_m) - \eta(t_n))^{2/(1-k)}. \] (106)
As
\[ \lim_{m,n \rightarrow \infty} \theta(\eta(t_m) - \eta(t_n)) = 0, \] (107)
by \((\theta_3)\), we have
\[ \lim_{m,n \rightarrow \infty} \theta(\eta(t_m) - \eta(t_n)) = 1. \] (108)
Thus (106) gives that
\[ \lim_{m,n \rightarrow \infty} d(x_m, x_n) = 0. \] (109)
Hence \( \{x_n\} \) is Cauchy sequence which converges to an element \( x_* \in \overline{U} \). As \( x_n \in \Lambda(x_n, t_n) \) for \( n \in \mathbb{N} \) and \( \Lambda \) is
closed, so \( x_\ast \in \Lambda(x_\ast, t_\ast) \). Also, from (I) we have \( x_\ast \in U \). Hence, \((x_\ast, t_\ast) \in Q\). Since \( A \) is totally ordered, therefore \((x, t) \leq (x_\ast, t_\ast)\) for each \((x, t) \in A\). That is, \((x_\ast, t_\ast)\) is an upper bound of \( A \). By Zorn's Lemma, the set \( Q \) admits a maximal element \((x_0, t_0)\). We claim that \( t_0 = 1 \). Assume, on the contrary, that \( t_0 < 1 \). Choose \( r > 0 \) and \( t \in (t_0, 1) \) such that \( B(x_0, r) \subset U \) and

\[
\theta(r) = \left[ \theta(\eta(t) - \eta(t_0)) \right]^{2/(1-k)}, \quad (111)
\]

Note that

\[
\theta(d(x_0, \Lambda(x_0, t))) \\
\leq \theta(d(x_0, \Lambda(x_0, t_0)) + H(\Lambda(x_0, t_0), \Lambda(x_0, t))) \\
\leq \theta(\eta(t) - \eta(t_0)) = (\theta(r))^{(1-k)/2} < (\theta(r))^{1-k}.
\]

Thus \( \Lambda(\cdot, t) : B(x_0, r) \rightarrow CB(X) \) satisfies all assumptions of Theorem 27. Hence, for all \( t \in [0, 1] \), there exists \( x \in B(x_0, r) \) such that \( x \in \Lambda(x, t) \). Hence \((x, t) \in Q \). Now, \( d(x_0, x) < r \) implies that

\[
\theta(d(x_0, x)) < \theta(r) = \left[ \theta(\eta(t) - \eta(t_0)) \right]^{2/(1-k)}, \quad (113)
\]

which further implies that \((x_0, t_0) < (x, t)\), a contradiction to the fact that \((x_0, t_0)\) is a maximal element.

Conversely, if \( \Lambda(\cdot, 1) \) has a fixed point, then by similar arguments to those given before, we obtain that \( \Lambda(\cdot, 0) \) has a fixed point. \( \square \)

4. Existence of a Solution of Second-Order Differential Equation

In this section, we study the existence of solutions of two-point boundary value problems associated with a second-order differential equation. Let \( X = C[0, 1] \) be the space of all continuous functions defined on \([0, 1]\). The metric on \( X \) is given by

\[
d(x, y) = \|x - y\|_\infty = \max_{t \in [0, 1]} |x(t) - y(t)|, \quad (114)
\]

Define the binary relation on \( X \) by

\[
(x, y) \in \mathcal{R} \quad \text{if and only if} \quad x \leq y \\
\text{(i.e.,} \ x(t) \leq y(t), \ t \in [0, 1]). \quad (115)
\]

Note that the space \( X = (C[0, 1], d) \) is complete metric space. We consider the following two-point boundary value problem:

\[
\begin{align*}
-x''(t) &= f(t, x(t)), \quad t \in [0, 1] \\
x(0) &= x(1) = 0,
\end{align*} \quad (116)
\]

where \( f : [0, 1] \times \mathbb{R} \rightarrow \mathbb{R} \) is a continuous function. Then, the problem (116) can be written in the following integral form:

\[
x(t) = \int_0^1 G(t, s) f(s, x(s)) \, ds, \quad (117)
\]

where the associated Green function is

\[
G(t, s) = \begin{cases} 
1 - s ; & 0 \leq t \leq s \leq 1 \\
(t - s) ; & 0 \leq s \leq t \leq 1,
\end{cases} \quad (118)
\]

see [21] for details.

**Theorem 29.** Assume that the following conditions are satisfied:

1. \( f : [0, 1] \times \mathbb{R} \rightarrow \mathbb{R} \) is continuous,
2. \( f(s, \cdot) : \mathbb{R} \rightarrow \mathbb{R} \) is increasing for all \( s \in [0, 1] \),
3. there exists \( \tau \in [1, \infty) \) such that the following condition holds for all \( x, y \in X \), with \( x \leq y \),

\[
|f(s, x) - f(s, y)| \leq 8e^{-\tau} |x(s) - y(s)|, \quad (119)
\]

\[\forall s \in [0, 1] \],

4. there exists \( x_0 \in X \) such that for all \( t \in [0, 1] \), we have

\[
x_0(t) \leq \int_0^1 G(t, s) f(s, x_0(s)) \, ds. \quad (120)
\]

Then the problem (116) has a solution in \( X \).

**Proof.** If we define the mapping \( T : X \rightarrow X \) by

\[
T(x)(t) = \int_0^1 G(t, s) f(s, x(s)) \, ds, \quad (121)
\]

then our problem can be written as a fixed point equation \( x = Tx \).

Obviously, \( T \) is continuous. As \( f(s, \cdot) \) is increasing, for any \( x, y \in X \) with \( x(t) \leq y(t) \) for all \( t \in [0, 1] \), we obtain that

\[
\int_0^1 G(t, s) f(s, x(s)) \, ds \leq \int_0^1 G(t, s) f(s, y(s)) \, ds, \quad (122)
\]

i.e., \( T(x)(t) \leq T(y)(t) \).

Thus, \( T \) is \( \mathcal{R} \)-closed. If \( x, y \in X \) such that \( x(t) \leq y(t) \), then we have

\[
|T(x)(t) - T(y)(t)| = \left| \int_0^1 G(t, s) f(s, x(s)) \, ds - \int_0^1 G(t, s) f(s, y(s)) \, ds \right|
\]

\[
\leq \int_0^1 G(t, s) |f(s, x(s)) - f(s, y(s))| \, ds \quad (123)
\]

\[
\leq \int_0^1 8e^{-\tau} |x(s) - y(s)| \, G(t, s) \, ds
\]

\[
\leq 8e^{-\tau} d(x, y) \int_0^1 G(t, s) \, ds.
\]
As \[ \int_0^1 G(t, s) ds = t/2 - t^2/2, \] we get that \( \sup_{t \in [0,1]} (\int_0^1 G(t, s) ds) = 1/8. \) The inequality (123) becomes

\[
|T(x)(t) - T(y)(t)| \leq 8e^{-\tau} d(x, y) \frac{1}{8} \leq e^{-\tau} d(x, y).
\]

(124)

Hence, we have

\[
\max_{t \in [0,1]} |T(x)(t) - T(y)(t)| \leq e^{-\tau} d(x, y),
\]

(125)

which implies that

\[
d(T(x), T(y)) \leq e^{-\tau} d(x, y).
\]

(126)

Taking square root on both sides and passing through exponential function, we obtain that

\[
e^{\sqrt{d(T(x), T(y))}} \leq e^{-\frac{\tau}{2}} d(x, y).
\]

(127)

where \( e^{-\tau} < 1 \) as \( \tau \geq 1. \) Hence,

\[
e^{\sqrt{d(T(x), T(y))}} \leq e^{\frac{\tau}{2}} e^{\sqrt{d(x, y)}} = e^{-\frac{\tau}{2}} e^{\sqrt{d(x, y)}}.
\]

(128)

Thus,

\[
\theta(d(Tx, Ty)) \leq (\theta(d(x, y)))^\alpha,
\]

(129)

where \( \theta(t) = e^{\sqrt{t}} \) and \( (x, y) \in \mathcal{R}. \)

As above inequality is true for any \( x, y \in X \) with \( x(t) \leq y(t), \) so is for any \( \varphi \in \Phi, \) with \( \varphi(d(x, Tx), d(x, y)) < 0. \) Thus

\[
\theta(d(Tx, Ty)) \leq (\theta(d(x, y)))^\alpha.
\]

(130)

By Theorem 24 we get that (116) has a solution in \( X. \) \( \square \)

5. Existence of a Solution of Fractional Boundary Value Problem

In this section, we investigate the existence of solutions of a nonlinear fractional differential equation. Let the space \( X \) and the metric \( d \) be defined as in the above section.

Consider the following fractional differential equation

\[
C^\beta D_t x(t) = f(t, x(t)); \quad 0 < t < 1, \quad 1 < \beta \leq 2,
\]

(131)

with boundary conditions

\[
x(0) = 0,
\]

\[
Ix(1) = x'(0).
\]

(132)

Here \( C^\beta D_t \) stands for the Caputo fractional derivative of order \( \beta, \) defined by

\[
C^\beta D_t f(t) = \frac{1}{\Gamma(n-\beta)} \int_0^t (t-s)^{n-\beta-1} f^n(s) ds,
\]

(133)

(where we consider \( n-1 < \beta < n \) and \( n = \lfloor \beta \rfloor + 1 \)) and \( I^\beta f \) denotes the Riemann-Liouville fractional integral of order \( \beta \) of a continuous function \( f, \) given by

\[
I^\beta f(t) = \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s) ds, \quad \text{with} \ \beta > 0.
\]

(134)

Senapati and Dey ([13]) showed that the problem (131)+(132) can be written in the following integral form:

\[
x(t) = \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s, x(s)) ds
\]

\[
+ \frac{2t}{\Gamma(\beta)} \int_0^1 \int_0^s (s-r)^{\beta-1} f(r, x(r)) dr ds.
\]

(135)

Theorem 30. Suppose that following conditions are satisfied:

1. \( f : [0,1] \times \mathbb{R} \rightarrow \mathbb{R} \) is a continuous function,

2. \( f(s, \cdot) : \mathbb{R} \rightarrow \mathbb{R} \) is an increasing function,

3. for every \( x, y \in X \) with \( x \leq y, \) the following condition holds:

\[
|f(s, x) - f(s, y)| \leq e^{-\frac{\tau}{4}} \frac{\Gamma(\beta + 1)}{4} |x(s) - y(s)|,
\]

(136)

\( \forall s \in [0,1], \)

where \( \tau \in [1, \infty), \)

4. there exists \( x_0 \in X \) such that, for all \( t \in [0,1], \) we have

\[
x_0(t) \leq \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s, x_0(s)) ds
\]

\[
+ \frac{2t}{\Gamma(\beta)} \int_0^1 \int_0^s (s-r)^{\beta-1} f(r, x_0(r)) dr ds.
\]

(137)

Then, (131)+(132) has at least one solution in \( C[0,1]. \)

Proof. Define the mapping \( T : X \rightarrow X \) by

\[
T(x)(t) = \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s, x(s)) ds
\]

\[
+ \frac{2t}{\Gamma(\beta)} \int_0^1 \int_0^s (s-r)^{\beta-1} f(r, x(r)) dr ds.
\]

(138)

Then (135) can be written as a fixed point equation for \( T; \) i.e.,

\( x \in \mathcal{R} \) if and only if \( x(t) \leq y(t), \ \forall t \in [0,1]. \)

(139)
By the given assumption (4), $X'(T; \mathcal{R})$ is nonempty. If $x, y \in X$ are such that $x(t) \leq y(t)$ for every $t$, then by assumption that $f(s, \cdot)$ is increasing we have

$$
\frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s, x(s)) \, ds \\
+ \frac{2t}{\Gamma(\beta)} \int_0^1 \int_0^t (s-r)^{\beta-1} f(r, x(r)) \, dr \, ds \\
\leq \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s, y(s)) \, ds \\
+ \frac{2t}{\Gamma(\beta)} \int_0^1 \int_0^t (s-r)^{\beta-1} f(r, y(r)) \, dr \, ds,
$$

which implies that $T(x)(t) \leq T(y)(t)$. Therefore, $T$ is $\mathcal{R}$-closed. Nieto and López [22] have shown that if there exists a sequence $\{x_n\}$ in $X$ such that $x_n(t) \leq x_{n+1}(t)$ and $x_n$ converges to some $x$, then $x_n$ converges to $x$. Hence, $\mathcal{R}$ is $d$-self closed. If $x, y \in X$ such that $x(t) \leq y(t)$, then

$$
\left| T(x)(t) - T(y)(t) \right| \\
= \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s, x(s)) \, ds \\
- \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} f(s, y(s)) \, ds \\
+ \frac{2t}{\Gamma(\beta)} \int_0^1 \int_0^t (s-r)^{\beta-1} f(r, x(r)) \, dr \, ds \\
- \frac{2t}{\Gamma(\beta)} \int_0^1 \int_0^t (s-r)^{\beta-1} f(r, y(r)) \, dr \, ds
$$

$$
\leq \frac{1}{\Gamma(\beta)} \left| \int_0^t f(s, x(s)) \, ds - f(s, y(s)) \, ds \right| \\
+ \frac{2}{\Gamma(\beta)} \left| \int_0^1 \int_0^t f(r, x(r)) \, dr \, ds - f(r, y(r)) \, dr \, ds \right|
$$

$$
\leq \frac{1}{\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} |f(s, x(s)) - f(s, y(s))| \, ds \\
+ \frac{2}{\Gamma(\beta)} \int_0^1 \int_0^t |f(r, x(r)) - f(r, y(r))| \, dr \, ds
$$

$$
\leq e^{-\tau} \frac{\Gamma(\beta+1)}{4\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} |x(s) - y(s)| \, ds \\
+ 2e^{-\tau} \frac{\Gamma(\beta+1)}{4\Gamma(\beta)} \int_0^1 \int_0^t |x(r) - y(r)| \, dr \, ds
$$

$$
\leq e^{-\tau} \frac{\Gamma(\beta+1)}{4\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} \, ds + 2e^{-\tau}
$$

$$
\Gamma(\beta+1) \frac{d(x, y)}{4\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} \, ds \leq e^{-\tau}
$$

$$
\Gamma(\beta+1) \frac{d(x, y)}{4\Gamma(\beta)} \left( \int_0^1 (s-r)^{\beta-1} \, dr \, ds + 2e^{-\tau} \right)
$$

$$
\leq \frac{\Gamma(\beta+1)}{4\Gamma(\beta)} \int_0^t (t-s)^{\beta-1} \, ds \leq e^{-\tau}
$$

$$
\Gamma(\beta+1) \frac{d(x, y)}{4\Gamma(\beta)} \left( \int_0^1 (s-r)^{\beta-1} \, dr \, ds + 2e^{-\tau} \right)
$$

where $B$ is the beta function. From the above inequality, we obtain that

$$
d(Tx, Ty) \leq e^{-\tau} d(x, y).
$$

Taking square root on both sides and passing through exponential function, we have

$$
e^\alpha \sqrt{d(Tx, Ty)} \leq e^{(e^\alpha - 1) d(x, y)},
$$

that is,

$$
e^\alpha \sqrt{d(Tx, Ty)} \leq (e^\alpha - 1)^\alpha d(x, y),
$$

where $\alpha = \sqrt{e^{-\tau} - 1} < 1$. Since the above inequality holds for any $x, y \in X$ such that $x(t) \leq y(t)$ so it is true for any $\varphi \in \Phi$, with

$$
\varphi(d(Tx, Ty), d(x, y)) < 0.
$$

Hence we have

$$
\theta(d(Tx, Ty)) \leq (\theta(d(x, y)))^\alpha.
$$

Thus $T$ is a Suzuki type $(\theta, \mathcal{R})$-contractive mapping. Since all the conditions of Theorem 24 are satisfied, the problem (131) has at least one solution. \hfill \square
