Immune regulation has been shown to be involved in the progressive growth of some murine tumors. Interruption of immune regulatory pathways via activation of 4-1BB or cytotoxic T-lymphocyte-associated antigen-4 (CTLA-4) blockade appears to be a promising strategy for cancer immunotherapy. In this study, we examined the effectiveness of 4-1BBL-expressing tumor cell vaccine in combination with CTLA-4 blockade on rejection of murine prostate cancer RM-1. We found that the combination of both a vaccine consisting of 4-1BBL-expressing RM-1 cells and CTLA-4 blockade resulted in regression of RM-1 tumors and a significant increase in survival of the tumour cell recipients, compared to that of either treatment alone. The combined vaccination resulted in higher CTL against RM-1 cells and increased secretion of IFN-γ, TNF-α, and IL-2 in the mix-cultured supernatant. These results suggest that combining activation of 4-1BB and blockade of CTLA-4 may offer a new strategy for prostate cancer immunotherapy.

1. Introduction

Prostate cancer (PCa) is the most frequently diagnosed cancer in old men and also the second leading cause of male cancer death in the western countries [1]. In addition, the incidence and mortality of carcinoma of prostate are increasing in China. Although radical prostatectomy and radiation therapy remain the optimal choice for localized stage of PCa, there is no effective treatment for patients who develop recurrences or develop into hormone-resistance prostate cancer (HRPC) or those who have metastatic disease at the time of diagnosis. Therefore, new therapeutic approaches to control or even eliminate residual tumor cells are definitely needed, providing an opportunity for immunotherapy [2].

It is well known that T-cell-mediated immune response plays a great important role in antitumor immunity. An effective T-cell response can attack tumor cells only after T cell receives two key signals from the peptide/MHC complexes and costimulatory signals (including B7-1/2, 4-1BBL, and CD40). Without costimulation, T-cells will undergo apoptosis or become anergic [3–5]. The fact that tumor cells are found to have low expression of costimulatory molecule may explain how tumor cells evade the immune surveillance. Consistent with this possibility, researchers demonstrated that conferring 4-1BBL expression to tumors of a variety of tissue origins was, in many cases, sufficient to promote tumor rejection by a CD8+ T-cell-dependent mechanism [6, 7].

4-1BBL (CD137L), the counterreceptor for 4-1BB, is a member of the TNF (ligand) superfamily and serves as a secondary signal to activated T cells. 4-1BB signaling can induce cytokine production, expansion, and functional maturation of T cells, dendritic cells, NK cells, and monocytes [8, 9]. With regard to tumor biology, binding of 4-1BB has been demonstrated to prevent and even rescue anergic CD8+ T cells in a number of tolerance-inducing models [10]. Also, 4-1BBL costimulation can retrieve CD28 expression in activated T cells [11]. A soluble 4-1BBL has also been shown to overcome immunological ignorance, allowing immunization with tumor-derived peptide to induce a protective CTL response [12].

CTLA-4, a close homolog of CD28, is upregulated on activated T cells and binds B7-1 and B7-2 with considerably greater avidity than CD28 results in the transduction of
an inhibitory signal and thereby functions as a negative regulator of T-cell activation in both CD4+ and CD8+ T cells [13]. When CTLA-4/B7 interactions are blocked by injection of anti-CTLA-4 monoclonal antibody during cancer vaccination, therapeutic T-cell immunity against even poorly immunogenic tumours such as B16 melanoma can be eliminated [14]. This effect is partly mediated by an increased expansion of antigen-specific CTL [15, 16]. It has been reported that blockade of CTLA-4/B7 interactions prevents induction of peripheral T-cell tolerance upon vaccination with peptides under tolerogenic conditions, suggesting that CTLA-4 might be actively involved in the induction of anergy [17].

In the present work, we investigated the effect of a vaccine combined with 4-1BBL-expressing tumor vaccine and CTLA-4 blockade on the survival of C57BL/6 mice transplanted subcutaneously with prostate cancer RM-1 cells. We found that 4-1BBL-expressing tumor vaccine in combination with CTLA-4 blockade was effective in reducing tumor incidence and increasing in survival of the tumour cell recipients.

2. Materials and Methods

2.1. Animals, Cell Lines, and Antibodies. Female C57BL/6 (H-2 Kb) mice, 6–8 weeks old, were obtained from Shanghai SLAC Laboratory Animal Co. Ltd (Shanghai, China). Animals were maintained at the Central Animal Facility of Wuhan University according to standard guidelines, and experiments were conducted according to the guidelines of the China Council for Animal Care. All mice are killed by cervical dislocation in the experiment. RM-1, a murine prostate cancer cell line, was obtained from Chinese Academy of Sciences (Shanghai, China). All cells were cultured in RPMI-1640 medium with 10% heat-inactivated FCS, 2 mM L-glutamine, 100 U/mL penicillin, and 100 μg/mL streptomycin at 37°C in a humidified atmosphere containing 5% CO₂. Anti-mouse CTLA-4 (clone 9H10) or hamster IgG isotype control was obtained from BioXCell; anti-4-1BBL isotype control was purchased from Santa Cruz.

2.2. Stable Transfection of RM-1 Cells with 4-1BBL Plasmid. The RM-1 cells were transfected with 2 μg of pCDNA3.1-4-1BBL or empty vector by the mediation of 6 μL Lipofectamine 2000 (Invitrogen, Carlsbad, CA, USA), according to the manufacturer’s instructions. After 2 days of culture, the cells were reseeded into a 10 cm dish and cultured for another 2 days; complete RPMI-1640 medium containing 1000 μg/mL G418 (Sigma, St. Louis, MO) was added to the culture. After 20 days of selection, all nontransfected cells died, and discrete clones were visible in transfected cells. These clones were expanded in the presence of 200 μg/mL G418; positive cells expressing 4-1BBL or not were named RM-1/4-1BBL and RM-1/pCDNA3.1.

2.3. Western Blot Analysis. To determine 4-1BBL expression, positive cells (5 × 10⁶) were lysed and subjected to SDS-PAGE. Then protein was transferred to a nitrocellulose membrane (Amersham, USA). The transferred membrane was probed with polyclonal goat anti-4-1BBL antibody, followed by a horseradish peroxidase-conjugated anti-goat IgG secondary antibody (Santa Cruz, CA). Antibodies on membrane were visualized by chemiluminescence (Pierce, Rockford, IL). Western blot for β-actin was used as an internal sample.

2.4. Subcutaneous Challenge and Immunization. Mice were shaved on the back and challenged subcutaneously with 2 × 10⁵ RM-1 cells in PBS. At the same day or later as indicated, parental and transduced cells were incubated with 100 μg/mL mitomycin C (MMC) for 1 h as cancer vaccine, and treatment was initiated by injecting 10⁶ cancer vaccine cells (in PBS) subcutaneously into the left flank and repeated 3 and 6 d later. Treatment with 9H10 or control hamster IgG was started simultaneously or 3 d later with similar results. Antibodies were delivered intraperitoneally at 100 μg in PBS, usually followed by two 50 μg injections every 3 d. Tumor growth was scored by measuring perpendicular diameters. Mice were killed when the tumors displayed severe ulceration or reached a size of 1000 mm².

2.5. Generation of CTL Cultures and CTL Assay. Spleens were harvested from mice rejecting RM-1 cells and restimulated in vitro with MMC-treated RM-1 cells, and recombinant human IL-2 was added to a final concentration of 50 IU/mL. After 7 d, cells were collected and purified by ficoll-histopaque (Sigma-Aldrich) gradient centrifugation and served as effector cells. Target cells (2.5 × 10³ per well) were cocultured with effector cells (5 × 10⁵ per well) at different E: T ratios in 96 round bottom plates. After a 48-hour incubation at 37°C, the amount of released lactate dehydrogenase was determined by using Cell Counting Kit-8 (Dojindo, Japan) assay according to the manufacturer’s instructions. All determinations were carried out in triplicate and repeated three times. The percentage of specific cytotoxicity was calculated as [target control – (experimental – effector control)/target control] × 100%.

2.6. Enzyme-Linked Immunosorbent Assay. 24 h after target cell coculture with effector cells, the supernatant was collected and tested for the presence of IFN-γ, TNF-α, and IL-2 by ELISA according to the manufacturer’s instructions (Pharmingen).

2.7. Statistical Analysis. Data were presented as mean ± standard deviation. Statistical differences were considered to be significant at a P value <0.05 as determined by an ANOVA or Student’s t-test using SPSS13.0. Comparison among groups in the survival data was made using the log-rank test.

3. Results

3.1. Establishment of RM-1 Cells Expressing 4-1BBL. RM-1 cells were transfected with pCDNA3.1 and pCDNA3.1/4-1BBL, and the G418-resistant cells (RM-1/pCDNA3.1, RM-1/4-1BBL) were selected. Western blot analysis showed the
expression of 4-1BBL in parental and transduced cells, respectively (Figure 1).

3.2. CTLA-4 Blockade Together with 4-1BBL-Expressing Cellular Vaccines Causes Rejection of RM-1 Tumors. To determine the effect of 4-1BBL-expressing cellular vaccines combined with CTLA-4 blockade on tumor growth in vivo, parental RM-1, RM-1/pCDNA3.1, and pCDNA3.1/4-1BBL cells were injected into the flank of mice. Tumor growth in mice injected with pCDNA3.1/4-1BBL cells was slower than that in mice injected with parental RM-1 or RM-1/pCDNA3.1. Administration of anti-CTLA-4 antibody 9H10 delayed growth of RM-1 tumors, but control hamster IgG had no effect. However, the combination of 4-1BBL-expressing vaccine and CTLA-4 blockade induced more obvious effectiveness on RM-1 tumor growth than either treatment alone. 4/5 mice rejected RM-1 tumors after the combined treatment (Figure 2).

3.3. CTLA-4 Blockade Together with 4-1BBL-Expressing Cellular Vaccines Increased CTL Activity and Production of Cytokines. To determine the immune function of 4-1BBL-expressing cellular vaccines combined with CTLA-4 blockade in vitro, CTL activity of splenocytes from immunized mice was evaluated. As shown in Figure 3, CTL activity of splenocytes from mice immunized with the combination of 4-1BBL-expressing vaccine and CTLA-4 blockade was dramatically higher than that from mice treated either alone. Vaccination with parental RM-1, RM-1/pCDNA3.1, and control hamster IgG had no effect on CTL activity. Also, the level of cytokines in supernatant cocultured cells was examined. The results showed that the levels of cytokines (IFN-γ, TNF-α, and IL-2) in supernatant from mice vaccinated with 4-1BBL-expressing vaccine and CTLA-4 blockade were much higher than that from mice immunized with either alone (Figure 4).

3.4. CTLA-4 Blockade Together with 4-1BBL-Expressing Cellular Vaccines Prolonged the Life Span of Mice Rechallenged Tumors. To determine the immune protection effect of 4-1BBL-expressing cellular vaccines combined with CTLA-4 blockade, mice were inoculated subcutaneously with lethal dose of parental RM-1 cells to monitor survival daily. The survival rate of mice immunized with both CTLA-4 blockade and 4-1BBL-expressing cellular vaccines was significantly higher than that of mice immunized with either alone (Figure 5).
Clinical and Developmental Immunology

4. Discussion

In the present study, we demonstrated that the preclinical effect of 4-1BBL-expressing cellular vaccines can be markedly improved by combining vaccination with treatment with anti-CTLA-4 mAb. The combination vaccine resulted in sustained tumor degradation in all the mice. Our treatment regimen holds great promise for a positive clinical effect in humans.

Actually, cancer occurrence and development has been demonstrated to be associate with escape from immune surveillance. The prostate cancer vaccine alone was unable to cause complete tumor regression, which could reflect either that the initial CD8+ T-cell-mediated antitumor immune response simply is not potent enough to completely eliminate all the cancer cells or that the cancer cells have lost their immunogenicity. There might be several reasons for that including (1) low-level expression of the major MHC molecules, (2) absence of recognized tumor Ags, (3) poor costimulatory molecule expression, or (4) some kind of immunosuppression of the CD8+ T-cell response such as TGF-β [18]. 4-1BB is an inducible member of the TNFR superfamily that has profound effects on T cells, including activation of both CD4+ and CD8+ T cells, enhanced expansion [19, 20], increased long-term survival [21, 22], and antiapoptosis of activation-induced CD8+ T cells [23]. Costimulation through 4-1BB can also promote enhanced production of cytokines such as IL-2, IL-4, and IFN-γ [19, 24]. Regarding this, we sought to understand the effect on tumor-specific T cell responses of simultaneously actively driving proliferation and survival through activation of the costimulatory receptor 4-1BB, while at the same time eliminating a major brake on expansion via blocking the coinhibitory receptor CTLA-4.

In murine experiments, activation of 4-1BB with 4-1BB mAb can lead to rejection of many tumours [25]. Indeed, phase I and II clinical trials using anti-4-1BB therapy for advanced cancers are underway [26]. However, anti-4-1BB antibodies can cause severe immune system anomalies when given systemically [27]. Thus, in the present study, we use 4-1BBL-expressing cellular vaccines for treatment of prostate cancer. Our data indicate that the 4-1BBL-expressing cellular vaccine did slow tumor growth when initiated at the time of tumor implantation and resulted in regression of tumors in about 2/5 of the mice. Moreover, the combination of 4-1BBL-expressing cellular vaccine with CTLA-4 blockade induced rejection of all tumors injected at the same day. These results suggest that 4-1BBL-expressing cellular vaccines can be markedly improved by combining vaccination with treatment with anti-CTLA-4 mAb. In the study, we demonstrated the number of CD8+ and CD4+ T cells in RM-1 tumors in mice immunized with anti-CTLA-4 mAb and 4-1BBL-expressing cellular vaccines (data not shown), which suggest enhancement of cytotoxicity of TIL might be a way for the combination of vaccine to execute antitumor effect. The same results were observed in B16 melanoma by Kocak et al. [28] and Curran et al. [29].

Our results demonstrated that CTL activity of splenocytes and cytokine from mice immunized with 4-1BBL-expressing cellular vaccines and CTLA-4 blockade was dramatically increased compared with that from mice immunized with either alone. Vaccination with parental RM-1,
cancer immunotherapy. The main effector cells performing CTL activity are CD8+ T cells, while the main cells producing cytokines are CD4+ T cells. Th1 cells play a critical role in cellular immunity by their cytokines activating CD8+ T cells. Long-term survival of mice immunized with 4-1BBL-expressing cellular vaccines and CTLA-4 blockade when rechallenged lethal dose of parental RM-1 cells indicated that the combination of vaccines excites antitumor immune response by activating CD8+ and CD4+ T cells.

The findings presented in this study have significant implications for immunotherapy in humans. Our results suggested that it is important to consider whether two treatments will act synergistically when developing an immunotherapeutic strategy. Moreover, they also suggest that CTLA-4 blockade may be a vital adjuvant for a 4-1BBL-expressing vaccine used to treat cancers.

5. Conclusion

In summary, we concluded that the combination of activation of 4-1BB and blockade of CTLA-4 has a higher potential antitumor effect and may offer a new strategy for prostate cancer immunotherapy.
