We study the inverses of block Toeplitz matrices based on the analysis of the block cyclic displacement. New formulas for the inverses of block Toeplitz matrices are proposed. We show that the inverses of block Toeplitz matrices can be decomposed as a sum of products of block circulant matrices. In the scalar case, the inverse formulas are proved to be numerically forward stable, if the Toeplitz matrix is nonsingular and well conditioned.

1. Introduction

Let

\[
T = \begin{bmatrix}
T_0 & T_{-1} & \cdots & T_{1-n} \\
T_1 & T_0 & \cdots & T_{2-n} \\
\vdots & \vdots & \ddots & \vdots \\
T_{n-1} & T_{n-2} & \cdots & T_0
\end{bmatrix}
\]

be an \( n \times n \) block Toeplitz matrix with blocks of size \( m \times m \). We use the shorthand \( T = (T_{i-j})_{i,j=1}^n \) for a block Toeplitz matrix. The block Toeplitz systems \( Tx = b \) arise in a variety of applications in mathematics, scientific computing, and engineering, for instance, image restoration problems in image processing, numerical differential equations and integral equations, time series analysis, and control theory [1–3]. If we want to solve more than one block Toeplitz linear system with the same coefficient matrix, then we usually solve four or so special block linear systems in order to determine the block Toeplitz inverse formula that expresses \( T^{-1} \) as the sum of products of block upper and block lower Toeplitz matrices. For example, Van Barel and Bultheel [4] gave an inverse formula for a block Toeplitz matrix and then derived a weakly stable algorithm to solve a block Toeplitz system of linear equations. The special structure of block Toeplitz matrices has resulted in some closed formulas for their inverses.

In the scalar case, Gohberg and Semencul [5] have shown that if the \((1,1)\)st entry of the inverse of a Toeplitz matrix \( T \) is nonzero, then the first and the last columns of the inverse of the Toeplitz matrix are sufficient to reconstruct \( T^{-1} \). In [6], an inverse formula can be obtained by the solutions of two equations (the so-called fundamental equations), where each right-hand side of them is a shifted column of the Toeplitz matrix. Later, Ben-Artzi and Shalom [7], Labahn and Shalom [8], Huckle [9], Ng et al. [10], and Heinig [11] have studied the Toeplitz matrix inverse formulas when the \((1,1)\)st entry of the inverse of a Toeplitz matrix is zero. In [12], Cabay and Meleshko presented an efficient algorithm (NPADE) for numerically computing \( \text{Padé} \) approximants in a weakly stable fashion. As an application of NPADE, it has been shown that it can be used to compute stably, in a weak sense, the inverse of a Hankel or Toeplitz matrix.

When \( m > 1 \), additional problems are encountered in obtaining the inverse formula of a block Toeplitz matrix. A well-known formula of Gohberg and Heinig can construct \( T^{-1} \), provided that the first and last columns together with the first and last rows of the inverse are known [13]. In [14], a set of new formulas for the inverse of a block Hankel or block Toeplitz matrix is given by Labahn et al. The formulas are expressed in terms of certain matrix \( \text{Padé} \) forms, which approximate a matrix power series associated with the block Hankel matrix. We refer the reader to [15, 16] for the computation of \( \text{Padé-Hermite} \) and simultaneous \( \text{Padé} \) systems in detail. In [7], Ben-Artzi and Shalom have proved that each inverse of a Toeplitz matrix can be constructed via three of its columns, and thus, a parametrization of the
set of inverses of Toeplitz matrices is obtained. Then they
generalized these results to block Toeplitz matrices; see [17].
In [18], Gemignani has shown that the representation of
\( T^{-1} \) relies upon a strong structure-preserving property of
the Schur complements of the nonsingular leading principal
submatrices of a certain generalized Bezoutian of matrix
polynomials.

In this paper, we focus our attention to the inverses of
block Toeplitz matrices with the help of the block cyclic
placement. In [19], Ammar and Gader have shown that
the inverse of a Toeplitz matrix can be represented as sums of
products of lower triangular Toeplitz matrices and circulant
matrices. The derivation of their results is based on the
idea of cyclic displacement structure. In [20], Gohberg and
Olshevsky also obtained new formulas for representation of
matrices and their inverses in the form of sums of products of
factor circulant, which are based on the analysis of the factor
cyclic displacement of matrices. The results in applications to
Toeplitz matrices generalize the Gohberg-Semencul, Ben-
Artzi-Shalom, and Heinig-Rost formulas. Motivated by a
number of related results on Toeplitz inverse formulas, we
study the representation of the inverses of block Toeplitz
matrices since block Toeplitz matrices have similar displace-
ment structure as Toeplitz matrices, all results about Toeplitz
matrices extend quite naturally to block Toeplitz matrices.

At first, for purposes of presentation, we adopt some
notations that will be used throughout the paper. We denote
the \( m \times m \) identity matrix by \( I_m \), \( E_i \) \( (i = 0, 1, \ldots, n - 1) \) means
a matrix of dimension \( mn \times m \) in which the \( (i + 1) \)-th block
is the identity matrix \( I_m \), and the remaining blocks are all
zeros. \( J \) is called an \( n \times n \) block reverse identity matrix, if \( J \)
has the identity matrices on the block antidiagonal and zero
elsewhere. Let \( A = (A_{ij}) \) be a block matrix or a block vector
with block size of \( m \times m \). \( A^t = (A_{ji}) \) is said to be the block
transpose of \( A \). By \( C(\varphi, \psi) \) we denote the block \( \varphi \)-circulant
with the first column \( r = [r_0, \ldots, r_{m-1}]^t \) with a block size of
\( m \times m \); that is, the matrix of form is defined by

\[
\begin{bmatrix}
  r_0 & \varphi r_{n-1} & \cdots & \varphi^2 r_1 \\
  r_1 & r_0 & \cdots & \varphi r_{n-1} \\
  \vdots & \vdots & \ddots & \vdots \\
  r_{n-1} & \cdots & r_1 & r_0 \\
\end{bmatrix}
\]

In this work, new formulas for the inverses of block
Toeplitz matrices are proposed. As is well known, any block
Toeplitz matrix \( T \) has a property of block persymmetry, that
is, \( HT^tJ = T \), where \( J \) is the block reverse identity matrix.
Unfortunately, the matrix inverse does not hold this property.
This can explain why the Gohberg-Heinig formula [13] needs
the first and last columns together with the first and last
rows of the inverse for constructing the inverse. For a block
Toeplitz matrix \( T \), let \( T_c \) and \( T_s \) be its block circulant
and block skew-circulant parts, respectively. The representation
\( T = T_c \cdot I + T_s \cdot I \) shows that there will exist block
circulant matrices \( A_i \) \( (i = 1, 2) \) and \( B_i \) \( (i = 1, 2) \) such that
\( T^{-1} = A_1 B_1 + A_2 B_2 \). In this paper, by solving four linear
equations with the same coefficient matrix \( T \), we decompose
the inverses of block Toeplitz matrices as a sum of products
of block circulant matrices. From the point of view of the
computation, the formulas involving block circulants instead
of block upper or lower Toeplitz matrices are more attractive.
For example, in the scalar case, matrix-vector product by
a circulant matrix is roughly twice as fast as matrix-vector
product by a triangular Toeplitz matrix of the same size.
In fact, the efficient multiplication of a Toeplitz matrix and
a vector is achieved by embedding the Toeplitz matrix in
a circulant matrix is roughly twice as fast as matrix-vector
product by a triangular Toeplitz matrix of the same size.
In the scalar case, we consider the stability of the
Toeplitz matrix inverse formulas. We show that if the
Toeplitz matrix is nonsingular and well conditioned, the
inverse formulas are numerically forward stable.

We summarize briefly the content of our paper. Section 2
reviews some fundamental concepts such as the factor cyclic
placement structure of a block matrix and every square
block matrix can be written as a sum of products of block
circulant matrices. In Section 3, we decompose the inverses
of block Toeplitz matrices as a sum of products of block
circulant matrices by solving four equations with the same
coefficient matrix \( T \). Some corollaries are also obtained in
this section. We discuss the stability of the inverse formulas of
scalar Toeplitz matrices in Section 4. Some remarks are given
in Section 5.

2. The Factor Block Cyclic Displacement

The inverse formulas derived in the next section depend on
some results of the factor block cyclic displacement of a block
matrix. The focus of this section lies upon the definitions and
the properties of the factor block cyclic displacement of a
block matrix. We start with the definition of the factor block
cyclic displacement.

Let \( Z_\varphi \) be the block \( \varphi \)-cyclic lower shift matrix defined by

\[
\begin{bmatrix}
  0 & \cdots & 0 & \varphi l \\
  I & 0 & \cdots & 0 \\
  0 & I & \cdots & 0 \\
  \vdots & \vdots & \ddots & \vdots \\
  0 & \cdots & 0 & I \\
\end{bmatrix}
\]

The block \( \varphi \)-cyclic displacement of an \( n \times n \) block matrix \( A \)
with blocks size of \( m \times m \) is defined as

\[
\nabla_\varphi (A) = A - Z_\varphi AZ_\varphi^t, \quad \varphi \neq 0.
\]

The number \( \alpha = \text{rank } \nabla_\varphi (A) \) is referred to as block \( \varphi \)-cyclic
displacement rank of the block matrix \( A \). Since all block
Toeplitz matrices have a special structure, it is not difficult to obtain that
\[
\nabla_\varphi(T) = \begin{bmatrix}
O & T_{-1} - \varphi T_{-n} & \cdots & T_{-n} - \varphi T_1 \\
T_1 - \frac{1}{\varphi} T_{-1} & O & \cdots & O \\
\vdots & \vdots & \ddots & \vdots \\
T_{n-1} - \frac{1}{\varphi} T_1 & O & \cdots & O
\end{bmatrix}
\]
\[
= E_0 \begin{bmatrix}
-T_n & T_1 - \frac{1}{\varphi} T_{-1} \\
T_1 - \varphi T_{n-1} & \cdots & \vdots & \vdots \\
\vdots & \vdots & \ddots & \vdots \\
T_{n-1} - \varphi T_1 & O & \cdots & O
\end{bmatrix} \cdot E_0^T,
\]
where \( T_m \) may be an arbitrary \( m \times m \) matrix. Therefore, the \( \varphi \)-cyclic displacement rank of a block Toeplitz matrix is at most \( 2m \).

By straightforward computations, it is easy to see that the equality \( \nabla_\varphi(A) = 0 \) holds if and only if \( A \) is a block \( \varphi \)-cyclic matrix. For any invertible block matrix \( A \) there exists a simple interrelation between the block \( \varphi \)-cyclic displacement of the inverse matrix \( A^{-1} \) and the block \( \varphi \)-cyclic displacement of \( A \). This connection is given by
\[
\nabla_\varphi(A^{-1}) = A^{-1} \nabla_\varphi(A) Z_\varphi A^{-1} Z_{\varphi}^{-1}
\]

From the previous equation, we know that the block \( \varphi \)-cyclic displacement rank of the inverse matrix \( A^{-1} \) is the same as that of \( A \). Moreover, the previous equation also allows us to make use of the block \( \varphi \)-cyclic displacement technique for the calculation of the inverse matrix. We will study the inverses of block Toeplitz matrices with the help of the block cyclic displacement. We need the following result.

**Theorem 1.** If the block \( \varphi \)-cyclic displacement of \( A \) is given as the sum
\[
A - Z_\varphi A Z_{\varphi}^{-1} = \sum_{m=1}^\alpha g_m h_m',
\]
where \( g_i \) and \( h_i \) (\( i = 1, \ldots, m \)) are \( n \times 1 \) block vectors with blocks of size \( m \times m \), then
\[
A = C(l, \varphi) + \frac{\varphi}{\varphi - \psi} \left( \sum_{m=1}^\alpha C(g_m, \psi) \cdot C(h_m, 1/\varphi)' \right)
\]
or
\[
A = C(l, \varphi) + \frac{\psi}{\varphi - \psi} \left( \sum_{m=1}^\alpha C(g_m, \varphi) \cdot C(h_m, 1/\varphi)' \right),
\]
where \( C(l, \varphi) \) is a block \( \varphi \)-cyclic matrix with the same last block row as that of \( A \) and \( C(l, \varphi) \) is the block \( \varphi \)-cyclic matrix with the same last block column as that of \( A \).

**Proof.** From computing the block \( \varphi \)-cyclic displacement of matrix \( A \) defined by (4), it then follows that
\[
\nabla_\varphi(A) = \nabla_\varphi(C(l, \varphi)) + \frac{\varphi}{\varphi - \psi} \left( \sum_{m=1}^\alpha C(g_m, \psi) \cdot C(h_m, 1/\varphi)' \right)
\]
\[
= \frac{\varphi}{\varphi - \psi} \sum_{m=1}^\alpha C(g_m, \psi) \cdot C(h_m, 1/\varphi)'.
\]

Note that the \( \varphi \)-cyclic displacement of any block matrix \( A \) is a linear operator and two block \( \varphi \)-cyclic matrices can commute; we obtain
\[
\nabla_\varphi(A) = \frac{\varphi}{\varphi - \psi} \sum_{m=1}^\alpha \nabla_\varphi(C(g_m, \psi)) \cdot C(h_m, 1/\varphi)'.
\]
By computing the block \( \varphi \)-cyclic displacement of block \( \varphi \)-cyclic matrix \( C(g_m, \psi) \) for all \( m \), we have
\[
\nabla_{\varphi}(A) = \frac{\varphi}{\varphi - \psi} \sum_{m=1}^\alpha \nabla_\varphi(C(g_m, \psi)) \cdot C(h_m, 1/\varphi)'
\]
\[
= \sum_{m=1}^\alpha g_m \cdot E_0' \cdot C(h_m, 1/\varphi)'
\]
\[
- \sum_{m=1}^\alpha E_0' \cdot \tilde{g}_m' \cdot C(h_m, 1/\varphi)',
\]
where \( \tilde{g}_m \) for \( m = 1, \ldots, \alpha \) are the first row of the block \( \varphi \)-cyclic matrices \( C(g_m, \varphi) \), respectively. Since \( E_0' \cdot C(h_m, 1/\varphi)' = h_m' \), it is easy to observe that the sum of the first \( \alpha \) terms in the previous equality is equal to \( \sum_{m=1}^\alpha g_m h_m' \).

In the following, we need to show that the sum of the last \( \alpha \) terms in the previous equality is equal to the zero matrix. Using the fact that \( Z^m_\varphi = \varphi l' \) and \( Z^{-1}_1 = Z_{1/\varphi}' \), we check
\[
\sum_{k=0}^{n-1} Z^k_\varphi (T^{-1} - Z_\varphi T^{-1} Z^{-1}_\varphi) Z^{-k}_\varphi = 0.
\]
Thus we obtain
\[
\sum_{k=0}^{n-1} Z^k_\varphi (T^{-1} - Z_\varphi T^{-1} Z^{-1}_\varphi) Z^{-k}_\varphi
\]
\[
= \sum_{k=0}^{n-1} Z^k_\varphi \cdot \sum_{m=1}^\alpha g_m h_m' \cdot Z^{-k}_\varphi
\]
\[
= \sum_{m=1}^\alpha C(g_m, \varphi) \cdot C(h_m, 1/\varphi)'
\]
\[
= 0.
\]
By comparing \( \sum_{m=1}^\alpha E_0' \cdot \tilde{g}_m' \cdot C(h_m, 1/\varphi)' \) with \( \sum_{m=1}^\alpha C(g_m, \varphi) \cdot C(h_m, 1/\varphi)' \), we obtain \( \sum_{m=1}^\alpha E_0' \cdot \tilde{g}_m' \cdot C(h_m, 1/\varphi)' = 0. \)
Finally, we discuss why \(C(\text{lr}, \varphi)\) is the block \(\varphi\)-circulant with the same last block rows as the matrix \(A\). We know that the last block row of the matrix \(C(g_m, \psi)\) is independent of the number \(\psi\). In view of \(C(\text{lr}, \varphi) \cdot C(h_n, 1/\varphi) = 0\), the last block rows of the matrix \(A\) and \(C(\text{lr}, \varphi)\) are the same.

Equation (8) is now completely proved. A similar argument shows that (9) can be obtained from (7). \(\square\)

3. Inverses of Block Toeplitz Matrices

In this section, we focus our attention to new formulas on the inverses of block Toeplitz matrices. It is easy to find that any block Toeplitz matrix has a property of block persymmetry, that is, \(JT^\top J = T\), where \(J\) is the block reverse identity matrix. Unfortunately, the matrix inverse does not have this property. This can explain why the Gohberg-Heiñig formula [13] needs the first and last block columns together with the first and last block rows of the inverse to construct it. Unlike the Gohberg-Semencul formula [5], it only needs the first and the last columns of the inverse if the \((1, 1)\)st entry of the inverse is nonzero.

Let

\[
T(x_0, x_1, \ldots, x_{n-1})' = E_0,
\]

(15)

\[
T(u_0, u_1, \ldots, u_{n-1})' = \left( T'_n, T'_1 - \frac{1}{\varphi} T'_{1-n}, \ldots, T'_{n-1} - \frac{1}{\varphi} T'_{1-n} \right)',
\]

(17)

\[
(\bar{u}_0, \bar{u}_1, \ldots, \bar{u}_{n-1})' = \left( T'_{n-1} - \frac{1}{\varphi} T'_{1-n}, \ldots, T'_{1} - \frac{1}{\varphi} T'_{1-n} \cdot T'_n \right).
\]

(18)

For convenience, we will write \(x, \bar{x}, u\) and \(\bar{u}\) as

\[
x = (x_0, x_1, \ldots, x_{n-1})', \quad \bar{x} = (\bar{x}_0, \bar{x}_1, \ldots, \bar{x}_{n-1})',
\]

\[
u = (u_0, u_1, \ldots, u_{n-1})', \quad \bar{u} = (\bar{u}_0, \bar{u}_1, \ldots, \bar{u}_{n-1}).
\]

(19)

From (5), (6), (15), and (17), by simple computations we obtain the following equality:

\[
\nabla_x (T^{-1}) = -T^{-1} \nabla_x (T) Z_\varphi T^{-1} Z_1'/\varphi
\]

Substituting (16) and (18) into the previous equality and computing, we obtain

\[
\nabla_x (T^{-1}) = \varphi \begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_{n-1} \end{bmatrix} \cdot \left( T'_{n-1} - \frac{1}{\varphi} T'_{1-n}, \ldots, T'_{1} - \frac{1}{\varphi} T'_{1-n} \cdot T'_n \right) \cdot T^{-1} Z_1'/\varphi
\]

Theorem 2. Let \(T\) be a block Toeplitz matrix given by (1). If (15)–(18) are solvable for some \(\varphi \neq 0\) and an arbitrary matrix \(T_n\) of order \(m\), then

\(\text{(a) } T\text{ is invertible;}\)

\(\text{(b) } T^{-1}\text{ can be denoted as}\)

\[
T^{-1} = \frac{\varphi}{\varphi - \psi} \left( C(x, \psi) \cdot C(J\bar{u}, \varphi) - \psi \left( u - \frac{\varphi - \psi}{\varphi} E_0, \psi \right) \cdot C(J\bar{x}, \varphi) \right),
\]

(22)

where \(\psi(\neq \varphi)\) is an arbitrary number.

Proof. (a) Assume that there exists nonzero vector \(p\) of dimension \(mn\) such that \(Tp = 0\). Then by computing (16) and (18), we have \((-T'_n, T'_1 - \varphi T'_{1-n}, \ldots, T'_{1-n} - \varphi T'_1)Z_\varphi p = 0\) and \((I_m, 0, \ldots, 0)Z_\varphi p = 0\). These imply \(\nabla_x (T) Z_\varphi p = 0\). Since \(\nabla_x (T) = T - Z_\varphi T'_{1/\varphi}\), we obtain \(TZ_\varphi p = 0\). A similar argument shows that \(TZ_\varphi^k p = 0\) for \(k = 2, 3, \ldots, n-1\).

Premultiplying the equalities \(TZ_\varphi^k p = 0\) by \((\bar{x}_0, \bar{x}_1, \ldots, \bar{x}_{n-1})\), we can conclude that all elements of the vector are equal to zero. Therefore, the invertibility of \(T\) is now proved.
(b) According to Theorem 1, we get
\[
T^{-1} = C(\text{lr}, \varphi) + \varphi C(\text{lr}, \psi) \cdot C\left(\psi Z_{1/\varphi}, 1/\varphi\right)' + C(U, \psi) \cdot C\left(\psi Z_{1/\varphi}, 1/\varphi\right)'.
\]
(23)

\(C(\text{lr}, \varphi)\) is the block \(\varphi\)-circulant matrix with the same last block row as that of \(T^{-1}\). It is not difficult to see that \(C(\text{lr}, \varphi) = C(\varphi Z_{1/\varphi}, 1/\varphi)' = C(J, \varphi)\). After computations and arrangement, we obtain the formula (22) on the inverses of block Toeplitz matrices.

Remark 3. In fact, the inverse formula (22) is a generalization of the formula of Gohberg and Olshevsky [20], where they consider scalar Toeplitz matrices. Since the matrix inverse does not hold the property of persymmetry, in the block case, for constructing \(T^{-1}\) we need to solve four linear equations with the same coefficient matrix \(T\). Labahn et al. also gave this conclusion in terms of certain matrix Padé forms [14].

Remark 4. For the inverse formula (22), we take an interest in two particular cases. When \(\varphi = 1\) and \(\psi = 0\), the inverse formula (22) can be written as
\[
T^{-1} = \begin{bmatrix}
0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 0 \\
x_{n-1} & x_1 & x_0 & 0
\end{bmatrix}
\]
\[
\times \begin{bmatrix}
\bar{u}_{n-1} & \bar{u}_0 & \cdots & \bar{u}_{n-2} \\
\bar{u}_{n-2} & \bar{u}_{n-1} & \cdots & \vdots \\
\bar{u}_0 & \ddots & \ddots & \vdots \\
\bar{u}_0 & \bar{u}_{n-2} & \bar{u}_{n-1} & 0
\end{bmatrix}
\times \begin{bmatrix}
u_0 - I_m & 0 & \cdots & 0 \\
u_1 & \nu_0 - I_m & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
u_{n-1} & \nu_1 & \cdots & 0
\end{bmatrix}
\times \begin{bmatrix}
\bar{x}_{n-1} & \bar{x}_0 & \cdots & \bar{x}_{n-2} \\
\bar{x}_{n-2} & \bar{x}_{n-1} & \cdots & \vdots \\
\vdots & \vdots & \ddots & \bar{x}_0 \\
\bar{x}_0 & \bar{x}_{n-2} & \bar{x}_{n-1} & 0
\end{bmatrix}
\]
(24)

So we obtain that the inverse of a block Toeplitz matrix can be represented as a sum of products of block lower triangular Toeplitz matrices and block circulant matrices. This is a generalization of the formula of Ammar and Gader [21], where they considered the Hermitian Toeplitz matrix.

Let \(y = (y_0, y_1, \ldots, y_{n-1})', z = (z_0, z_1, \ldots, z_{n-1})', y' = (\bar{y}_0, \bar{y}_1, \ldots, \bar{y}_{n-1})\) and \(z' = (\bar{z}_0, \bar{z}_1, \ldots, \bar{z}_{n-1})\) be the solutions of the equations \(Ty = E_{n}, Tz = E_{k+1}, \bar{y}' = E_{n-k-1}\), and \(\bar{z}'T = E_{n-k-1}'\) for some integer \(k (0 \leq k \leq n - 1)\), respectively. In addition, \(y_{n-1} = \bar{y}_0\) and \(z_{n-1} = \bar{z}_0\) are both nonsingular, \(\chi_{j0} \sum_{i=1}^{n-1} \bar{y}_i T_{n-i} = \sum_{i=1}^{n-1} T_{n-i} y_{n-i} = (\varphi) y_{n-1} + \sum_{i=1}^{n-1} T_{n-i} y_{n-i}\) for \(0 \leq k \leq n - 2\) and \((1/\varphi) \sum_{i=1}^{n-1} \bar{y}_i T_{n-i} = (1/\varphi) y_{n-1} + \sum_{i=1}^{n-1} T_{n-i} y_{n-i}\) for \(k = n - 1\). For \(k < n - 1\), we have \(T_n = T_0 + (1/\varphi) \sum_{i=1}^{n-1} T_{n-i} y_{n-i} = T_0 + (1/\varphi) \sum_{i=1}^{n-1} \bar{y}_i T_{n-i}\). Then we obtain
\[
Tu = T \frac{1}{\varphi} \left(Z \varphi y - z\right) y_{n-1}'
\]
\[
= \frac{1}{\varphi} T \frac{\varphi y_{n-1} - 0}{y_{n-1}} y_{n-1}'
\]
\[
+ \frac{1}{\varphi} T \frac{0}{y_{n-1} - 1/\varphi T z y_{n-1}} y_{n-2}'
\]
\[
\begin{bmatrix}
T_0 \\
T_1 \\
\vdots \\
T_{n-1}
\end{bmatrix}
+ \frac{1}{\varphi}
\begin{bmatrix}
\varphi(T_n - T_0) y_{n-1} \\
-T_{n-1} y_{n-1} \\
\vdots \\
-T_1 y_{n-1}
\end{bmatrix}
\times y_{n-1} + \frac{1}{\varphi}E_{k+1} y_{n-1} - \frac{1}{\varphi}E_{k+1} y_{n-1}
\]
\[
\begin{bmatrix}
T_n \\
T_1 - \frac{1}{\varphi}T_{n-1} \\
\vdots \\
T_{n-1} - \frac{1}{\varphi}T_{n-1}
\end{bmatrix}
\]
\[
\bar{u}^T = \frac{1}{\varphi} y_0^{-1} \left( \bar{y}' Z_\varphi - \bar{z}' \right) T
\]
\[
= \frac{1}{\varphi} y_0^{-1} \left( \bar{y}_0, \ldots, \bar{y}_0 \right) T
+ \frac{1}{\varphi} y_0^{-1} \left( \bar{y}_1, \ldots, \bar{y}_{n-1}, 0 \right) - \frac{1}{\varphi} y_0^{-1} \bar{z}' T
= \left( T_{n-1}, T_1, T_0 \right)
+ \frac{1}{\varphi} y_0^{-1} \left( -\bar{y}_0 T_{n-1}, \ldots, -\bar{y}_0 T_{n-1}, \bar{y}_0 (T_n - T_0) \right)
+ \frac{1}{\varphi} y_0^{-1} E_{n-k-1} - \frac{1}{\varphi} y_0^{-1} E_{n-k-1}
= \left( T_{n-1} - \frac{1}{\varphi} T_{n-1}, \ldots, T_1 - \frac{1}{\varphi} T_{n-1}, T_n \right).
\]

For \( k = n - 1 \), we have \( T_n - T_0 = (1/\varphi) y_0^{-1} + (1/\varphi) \sum_{k=1}^{n-2} T_{n-k-1} y_{n-1} = (1/\varphi) y_0^{-1} + (1/\varphi) \sum_{k=1}^{n-2} \bar{y}_k T_{n-k} \).

A similar argument shows that
\[
Tu = \begin{bmatrix}
T_n \\
T_1 - \frac{1}{\varphi}T_{n-1} \\
\vdots \\
T_{n-1} - \frac{1}{\varphi}T_{n-1}
\end{bmatrix},
\]
\[
\bar{u}^T = \left( T_{n-1} - \frac{1}{\varphi} T_{n-1}, \ldots, T_1 - \frac{1}{\varphi} T_{n-1}, T_n \right).
\]

As a result, we obtain that \( u = (1/\varphi)(Z_\varphi y - z) y_0^{-1} \) and \( \bar{u}' = (1/\varphi) y_0^{-1} \left( \bar{y}' Z_\varphi - \bar{z}' \right) \) are the solutions of (17) and (18), respectively. This result together with Theorem 2 yields the following corollary.

**Corollary 5.** Let \( T \) be the block Toeplitz matrix given by (1). If (15) and (16), \( Ty = E_{k+1} Tz = E_{n-k+1} \bar{y}' T = E_{n-k-1} \bar{y}' T \) are solvable for some integer \( k \) \((0 \leq k \leq n - 1)\), in addition, \( y_{n-1} \) and \( y_0 \) are both nonsingular,
\[
\bar{y}_0^{-1} \sum_{i=1}^{n-1} \bar{y}_i T_{n-i} = \sum_{i=1}^{n-1} T_{n-i} y_{n-1} - 1 \text{ for } 0 \leq k \leq n - 2 \text{ and }
(1/\varphi) y_0^{-1} + \bar{y}_0^{-1} \sum_{i=1}^{n-1} \bar{y}_i T_{n-i} = (1/\varphi) y_0^{-1} + \sum_{i=1}^{n-1} T_{n-i} y_{n-1} - 1 \text{ for } k = n - 1, \text{ then } T \text{ is invertible and }
\]
\[
T^{-1} = \frac{1}{\varphi - \psi} \left( C(x, \varphi) \cdot C(J \bar{y}_0^{-1} (Z_\varphi \bar{y} - \bar{z}), \varphi) \right)
- C((Z_\varphi y - z) y_{n-1}, \psi) \cdot C(J x, \varphi) \right).
\]

**Corollary 6.** Let \( T \) be the block Toeplitz matrix given by (1). If (15) and (16), \( Ty = E_{n-k+1} \bar{y}' T = E_{n-k-1} \bar{y}' T \) are solvable, in addition, \( y_{n-1} \) and \( y_0 \) are both nonsingular, \( \bar{y}_0^{-1} \sum_{k=1}^{n-1} \bar{y}_k T_{n-k} = \sum_{k=1}^{n-1} T_{n-i} y_{n-1} - 1 \), then \( T \) is invertible and
\[
T^{-1} = \frac{1}{\varphi - \psi} \left( C(x, \varphi) \cdot C(J \bar{y}_0^{-1} (Z_\varphi \bar{y} - \bar{z}), \varphi) \right)
- C((Z_\varphi y - z) y_{n-1}, \psi) \cdot C(J x, \varphi) \right).
\]

4. **Stability Analysis**

In the scalar case, the inverse formula (22) in Section 3 is just the well-known formula of Gohberg and Heinig. In [13], the authors have shown that the first and last block columns together with the first and last block rows of the inverse are sufficient to construct the inverse \( T^{-1} \). In addition, we decompose the inverses of block Toeplitz matrices as a sum of products of block circulant matrices.
solution \( x \) in the sense that the relative error \( \| x - \hat{x} \|_2 / \| x \|_2 \) is small. In the matrix computation, roundoff errors occur. Let \( A, B \in C^{n \times n} \) and \( \alpha \in C \); if we neglect the \( O(\varepsilon^2) \) terms, then for any floating-point arithmetic with machine precision \( \varepsilon \), there are

\[
\begin{align*}
\text{fl}(\alpha A) &= \alpha A + E, \\
\| E \|_F &\leq \varepsilon |\alpha| \| A \|_F \leq \varepsilon \sqrt{n} |\alpha| \| A \|_2, \\
\text{fl}(A + B) &= A + B + E, \\
\| E \|_F &\leq \varepsilon \| A + B \|_F \leq \varepsilon \sqrt{n} \| A + B \|_2, \\
\text{fl}(AB) &= AB + E, \\
\| E \|_F &\leq \varepsilon \| AB \|_F \leq \varepsilon \sqrt{n} \| AB \|_2.
\end{align*}
\]

(32)

See [22]. According to the floating-point arithmetic, we have the following result.

**Theorem 7.** Let \( T \) be a nonsingular Toeplitz matrix given by (1) with \( m = 1 \) and let it be well conditioned then the inversion formula (30) is forward stable for \( \psi \neq 0 \) and a given number \( \psi (\neq \varphi) \).

**Proof.** Assume that we have computed the solutions \( \hat{x}, \hat{u} \) in the inverse formula (30) which are perturbed by the normwise relative errors bounded by \( \hat{e} \)

\[
\begin{align*}
\| \hat{x} \|_2 &\leq \| x \|_2 (1 + \hat{e}), \\
\| \hat{u} \|_2 &\leq \| u \|_2 (1 + \hat{e}).
\end{align*}
\]

(33)

Let \( N = \max\{1, \psi\} \) and \( M = \max\{1, \varphi\} \). Then, we have

\[
\begin{align*}
\| C_{11} \|_F &\leq \sqrt{n} N \| x \|_2, \\
\| C_{12} \|_F &\leq \sqrt{n} M \| u \|_2, \\
\| C_{21} \|_F &\leq \sqrt{n} \left( \frac{\psi - \psi}{\varphi} \right)^2 + n^2 N \| u \|_2^2, \\
\| C_{22} \|_F &\leq \sqrt{n} M \| x \|_2.
\end{align*}
\]

By using the perturbed solutions \( \hat{x}, \hat{u} \), the inverse formula (30) can be expressed as

\[
\hat{T}^{-1} = \text{fl} \left( \frac{\varphi}{\varphi - \psi} \left( C_{11} \hat{C}_{12} + C_{21} \hat{C}_{22} \right) \right) \\
\quad = \text{fl} \left( \frac{\varphi}{\varphi - \psi} \left( (C_{11} + \Delta C_{11}) (C_{12} + \Delta C_{12}) \\
\quad \quad \quad + (C_{21} + \Delta C_{21}) (C_{22} + \Delta C_{22}) \right) \right)
\]

(34)

\[
\hat{T}^{-1} = T^{-1} + \frac{\varphi}{\varphi - \psi} \left( \Delta C_{11} C_{12} + C_{11} \Delta C_{12} + \Delta C_{21} C_{22} \right.
\]

\[
\quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad + C_{21} \Delta C_{22} + E + F \right) + G.
\]

Here, \( E \) is the matrix containing the error which results from computing the matrix products, \( F \) contains the error from subtracting the matrices, and \( G \) represents the error of the multiplication by \( \psi / (\varphi - \psi) \).

For the error matrices \( \Delta C_{11}, \Delta C_{12}, \Delta C_{21}, \) and \( \Delta C_{22}, \) we have

\[
\begin{align*}
\| \Delta C_{11} \|_F &\leq \hat{e} \| C_{11} \|_F \leq \varepsilon \sqrt{n} N \| x \|_2, \\
\| \Delta C_{12} \|_F &\leq \hat{e} \| C_{12} \|_F \leq \varepsilon \sqrt{n} M \| u \|_2, \\
\| \Delta C_{21} \|_F &\leq \hat{e} \varepsilon \sqrt{n} \left( \frac{\psi - \psi}{\varphi} \right)^2 + n^2 N \| u \|_2^2, \\
\| \Delta C_{22} \|_F &\leq \hat{e} \varepsilon \sqrt{n} N \| x \|_2.
\end{align*}
\]

(36)

It follows that

\[
\begin{align*}
\| E \|_F &\leq \| E \|_F \\
&\leq \varepsilon \sqrt{n} \| T^{-1} \|_2, \\
&\leq \varepsilon \sqrt{n} \| T^{-1} \|_2, \\
&\leq \varepsilon \sqrt{n} \| T^{-1} \|_2,
\end{align*}
\]

(37)

After adding all these error bounds, we have

\[
\begin{align*}
\left\| T^{-1} - \hat{T}^{-1} \right\|_2 &\leq \frac{\varphi}{\varphi - \psi} \left( 2 \hat{e} n + \epsilon n^2 + \epsilon n \right) \\
&\quad \times M \| x \|_2 \left( \frac{\psi - \psi}{\varphi} \right) + 2N \| u \|_2 \\
&\quad + \frac{\epsilon \sqrt{n} \epsilon}{\varphi - \psi} \| T^{-1} \|_2,
\end{align*}
\]

(38)

Note that \( x \) and \( u \) are the solutions of (15) and (17), respectively; then \( \| x \|_2 \leq \| T^{-1} \|_2 \) and \( \| u \|_2 \leq \| T^{-1} \|_2 \) \( f \|_2 \),

where \( f = (T_n, T_1 - (1/\varphi)T_{1-n}, \ldots, T_{n-1} - (1/\varphi)T_{-1})^T \). Thus, the relative error is

\[
\begin{align*}
\left\| T^{-1} - \hat{T}^{-1} \right\|_2 &\leq \frac{\varphi}{\varphi - \psi} \left( 2 \hat{e} n + \epsilon n^2 + \epsilon n \right) \\
&\quad \times M \left( \frac{\psi - \psi}{\varphi} \right) + 2N \left\| T^{-1} \|_2 \right\|_2 \\
&\quad + \frac{\epsilon \sqrt{n} \epsilon}{\varphi - \psi}.
\end{align*}
\]

(39)

As \( T \) is well conditioned, thus, \( \| T^{-1} \|_2 \) is finite. Obviously, \( f \|_2 \) is finite. Therefore, the formula (30) presented in this section is forward stable.

For example, there are two particular cases of the inverse formula (30). When \( \varphi = 1 \) and \( \psi = -1 \), the inverse formula

\[
T^{-1} = \left( 1/2 \right) (C(x, -1) \cdot C(u, 1) - C(u - 2E_0, -1) \cdot C(x, 1)),
\]

where \( C(a, b) = \sum_{k=-\infty}^{\infty} e^{-ik} c_k e^{i(b-k)a} \).

Theorem 7 implies the following corollary.

**Corollary 7.** Let \( T \) be a nonsingular Toeplitz matrix given by (1) with \( m = 1 \) and let it be well conditioned then the inversion formula (30) is forward stable for \( \psi \neq 0 \) and a given number \( \psi (\neq \varphi) \).

**Proof.** This follows from Theorem 7 by similar arguments.
which denotes $T^{-1}$ as a sum of products of skew-circulant and circulant matrices, is numerically forward stable for a well-conditioned and nonsingular Toeplitz matrix $T$. In fact, this is the formula of Ammar and Gader in [21]. And when $\varphi = 1$ and $\psi = 0$, this is the formula of Ammar and Gader in [19]. The inverse formula $T^{-1} = C(x, 0) \cdot C(u, 1) - C(u - E_0, 0) \cdot C(x, 1))$ in which skew-circulant matrices are replaced by upper triangular factors is also forward stable, if $T$ is nonsingular and well conditioned.

We also find that even when $\psi = \infty$ and a given number $\varphi \neq 0$, the inverse formula (30) is still numerically forward stable. A similar argument can show that the inverse formulas in Corollaries 5 and 6 for the scalar case are all numerically forward stable when $T$ is nonsingular and well conditioned.

5. Concluding Remarks

In this paper, with the help of the block cyclic displacement, the inverses of block Toeplitz matrices are discussed. New formulas for inversion of block Toeplitz matrices are obtained, which can be decomposed in a sum of products of block circulant matrices. In the scalar case, we analyze the stability of the inverse formulas. In addition, it should be remarked that any mention of matrix Padé forms for representing inverses of Toeplitz matrices could also be given in terms of solving block linear systems. Also the proofs of the inverses formulas in [14] could also be extended to prove the inverse formulas in this work.
