This paper aims at determining the measure of \( Q \) under necessary and sufficient conditions. The measure is an equivalent measure for identifying the given \( P \) such that the process with respect to \( P \) is the deflator locally martingale. The martingale and locally martingale measures will coincide for the deflator process discrete time. We define \( s \)-viable, \( s \)-price system, and no locally free lunch in ordered Banach algebra and identify that the \( s \)-price system \((\mathcal{C}, \pi)\) is \( s \)-viable if and only a character functional \( \psi|_{\mathcal{C}} \leq \pi \) exists. We further demonstrate that no locally free lunch is a necessary and sufficient condition for the equivalent martingale measure \( Q \) to exist for the deflator process and the subcharacter \( \phi \in \Gamma \) such that \( \phi|_{\mathcal{C}} = \pi \). This paper proves the existence of more than one condition and that all conditions are equivalent.

1. Introduction

In this paper, we combine certain concepts in the functional analysis with other concepts in financial mathematics to generate new results. These results are crucial to the improvement of efficient markets and the stock market. Czkwianianc and Pazkiewicz [1] highlighted the martingale measure for the stochastic process with discrete time; Harrison and Kreps [2] investigated the fundamental theorem and confirmed that the equivalent martingale measure is not sufficient to no-arbitrage alone for the stochastic process.

In this paper, we introduce the deflator process and determine the necessary and sufficient conditions of
equivalent locally martingale for deflator process using ordered Banach algebra and other analytic concepts, such as algebra cone and character. We define certain concepts such as $s$-viable, $s$-price system, and $s$-no free lunch. We demonstrate the necessary and sufficient condition for the existence of the equivalent locally martingale measure. Different solutions have been introduced in relation to the topological conditions of arbitrage. Generally, some results validate the relation of no-arbitrage conditions to the existence of an equivalent locally martingale measure for deflator process.

The triple $(\Omega, F, P)$ is called the probability space, where $\Omega$ is a nonempty set, $F$ is a $\sigma$-field on $\Omega$, and $P$ is a probability measure. The process $S$, sometimes denoted as $(S_t)_{t \geq 0}$, is the process adapted to filter $\{F_t\}_{t \geq 0}$. The probability measure $Q$ defined on $F$ is equivalent to $P$ if $Q$ and $P$ contain the same null sets. The equivalent probability measure $Q$ is the equivalent martingale measure $\{S_t\}_{t \geq 0}$ if $\{S_t\}_{t \geq 0}$ is martingale with respect to $Q$. Thus, if $S$ is integrable with respect to $Q$ and for all $t \in T, E(S_t - S_{t-}/F) = 0$. A probability measure $Q$ is an equivalent local martingale measure for $S$ if $Q$ is equivalent to $P$ and $S$ is $Q$-local martingale.

This paper is divided into four sections. Section 1 introduces the research. Section 2 explains the concepts and definitions required in the main subject as locally martingale, ordered Banach algebra, trading strategy, deflator process, subcharacter, s-price system, s-viable, and s-no arbitrage. The classes of martingale and locally martingale measures coinciding with the discrete-time filtrated probability measure are discussed, and the existence of a one-to-one correspondence between equivalent martingale measure $Q$ for the deflator process and the subcharacter $\phi \in \Gamma$ such that $\phi|_{C} = \pi$ and some properties are proposed. In Section 3, the relationship between the equivalent locally martingale measure and the $s$-no-arbitrage is determined and the $s$-price system $(C, \pi)$ is confirmed to be no-arbitrage if and only if a deflator process exists. An equivalent locally martingale measure exists if and only if a uniformly integrable deflator process exists. We prove that if $S$ is a $\mathbb{R}^{d+1}$-valued semimartingale with nonnegative components defined on the filtered probability space $(\Omega, F, \{F_t\}_{t \geq 0}, P)$, an equivalent local martingale measure for deflator process also exists. Section 4 shows the relation between the deflator process and $s$-no-arbitrage, and we prove the uniformly integrable deflator process is necessary and sufficient condition to existence the equivalent locally martingale measure. Section 5 discusses the important conclusions of the research.

2. Preliminary

Consider a filtered probability space $(\Omega, F; \{F_t\}_{t \geq 0}, P)$ where $I \subset [0, 1]$ with 0, $T \in I$, for a fixed $T < \infty$. Let $F_0 = \{F, \Omega\}$, $F_T = F, S = (S(t))_{t \in I}$ be a $\mathbb{R}^{d+1}$-valued stochastic process with components $S_i(t)$ for $i = 0, 1, \ldots, d$ and satisfy the following properties:

(1) $S_i$ is an adapted to $\{F_t\}_{t \geq 0}$ for all $i = 0, 1, \ldots, d$

(2) $E((S_i^2(t))) < \infty$ for $t \in I$ and for all $i = 0, 1, \ldots, d$

(3) $S_0(t, \omega) = 1$ for all $t \in I$ and for all $\omega \in \Omega$.

**Definition 1** (see [22]). Let $(\Omega, F, P)$ be a complete probability space and $\{F_t; t \geq 0\}$ be a right continuous filtration. A right continuous adapted process $\{S_t; t \geq 0\}$ is locally martingale if there exists a sequence $\{\tau_n; n \geq 1\}$ of stopping time of filtration satisfying the following:

(1) $\tau_n \leq \tau_{n+1}$

(2) $P[\tau_n \leq n] = 1$

(3) $P[\lim_{n} \tau_n = \infty] = 1$

(4) If $\{\tau_n^t, t \geq 0\}$ is uniformly integrable martingale. Then, for each $n, \{S_t^\tau, F_t, t \geq 0\}$ is a uniformly integrable martingale. This concept plays a key role in the analysis. A positive local martingale $\{S_t^\tau, F_t, t \geq 0\}$ is super martingale, that is, let $A \in F_{\tau^t}, 0 \leq s \leq t$. Now, the set $\{X^\tau, t \geq 0\}$ is uniformly integrable.

For all $\alpha \geq 0$, $\{w: \lim_{n} \tau_n = \infty\} = \bigcup_{\alpha \geq 0} \lim_{n} \tau_n = \Omega \setminus \{\omega: \tau_n \geq 0\}$ $\bigcup_{\alpha < \infty} B_{\alpha, n}$ differs from $\Omega$ by a $P$-null set and thus $B_{\alpha, n} \in F_{\tau^t}$ for all $n \geq 1$ and $B_{\alpha, n} \subset B_{\alpha+1, n}$ almost everywhere. Hence,

$$\int \bigcup_{\alpha < \infty} \omega X_t dP = \lim_{n} \int \bigcup_{\alpha < \infty} \omega X_t dP = \lim_{n} \int \bigcup_{\alpha < \infty} \omega X_t dP.$$
Definition 4 (see [21]). Let A be a real Banach algebra with identity 1 and C nonempty subset of A. We call A a cone if the following hold:

1. \( a + b \in C \) for all \( a, b \in C \).
2. \( \lambda a \in C \) for all \( a \in C \) and \( \lambda \geq 0 \).

If \( C \cap -C = \{0\} \), then C will be called a proper cone. Any cone C on A induced an ordering \( \geq \) on A as follows: \( b \geq a \) if and only if \( b - a \in C \) for all \( a, b \in C \).

We say that C is algebra cone if

1. \( a \cdot b \in C \) for all \( a, b \in C \).
2. \( e \in C \).

Definition 5 (Ordered Banach algebras, see [21]). A Banach algebra A with unite A is called ordered Banach algebra, which is denoted by (OBA) when A is ordered by a relation \( \geq \) such that for every \( a, b \in A \) and \( b \geq 0 \),

1. \( a + b \geq 0 \Rightarrow a + b \geq 0 \).
2. \( a \geq 0, b \geq 0 \Rightarrow \lambda a \geq \lambda b \).
3. \( a, b \geq 0 \Rightarrow ab \geq 0 \).
4. \( e \geq 0 \).

So, if A is ordered by an algebra cone C, we will obtain \((A, C)\) as an ordered Banach algebra.

If A is (OBA) and C is an algebra cone, C is called normal if there is \( \beta > 0 \) for any \( a, b \in A \), \( 0 \leq a \leq b < \Rightarrow \|a\| \leq \beta b \).

Theorem 1 (see [24]). Let M and N locally martingales and S and T be stopping times. Then,

1. The sum \( M + N \) is also local martingale.
2. If T reduces M and \( S \subseteq T \), then S reduces M.
3. If both S and T reduce, then \( S \cup T \) also reduces.
4. The processes \( M^T \) and \( M^{T}_{(T \geq 0)} \) are local martingale.

We start the section by definition of trading strategy as follows:

Definition 6. A trading strategy H is an \( R^{d+1} \)-valued vector stochastic process, \( H = (\varphi(t)^0, \ldots, \varphi(t)^{d+1})_{t \geq 0} \), such that \( \varphi(t) \) is a \( F_{t-1} \)-measurable function for all \( t \geq 1 \), integrable with respect to semimartingale \( M = (S(t))_{t \geq 0} \).

Let \( V_t(H) = H \cdot M = \varphi(t)^0 S_t + \varphi(t)^1 S_t + \ldots + \varphi(t)^m S_t \), where \( H = (\varphi(t)^0, \ldots, \varphi(t)^{d+1}) \).

The process \( V_t(H) \) is called value process of \( H \).

Definition 7. Let \( S_i, i = 0, 1, \ldots, m \), be a strictly positive semimartingale; we set \( S = (S_0, S_1, \ldots, S_m) \) and \((X(t))_{t \geq 0} \) as a sequence of random variables, which is strictly positive for \( t \in [0, 1, \ldots, T] \). We call \((X(t))_{t \geq 0}^T \) a deflator random variable, and a measurable function \( \bar{S} = ((S^l/X(t)), (S^m/X(t)), \ldots, (S^n/X(t))) \) is called deflator process.

Definition 8. A functional \( \pi \) on ordered Banach algebra is called a subcharacter if \( \pi \) is a sublinear functional on C and \( \pi(x \cdot y) = \pi(x) \cdot \pi(y) \). The set of all subcharacters is denoted by \( \Gamma \).

Definition 9. The s-price system is a pair \((C, \pi)\) where \( C \) is an algebra cone of A and \( \pi \) is a subcharacter.

Definition 10. The s-price system \((C, \pi)\) is s-viable if \( \pi(x) \leq 0 \) and \( x \pm y \) for all \( y \in C \) such that \( \pi(y) \leq 0 \), in a special case if \( e \geq x \) with \( \pi(x) \leq 0 \).

Definition 11. Let \((A, C)\) be (OBA) with the algebra cone \( C = A_+ \setminus \{0\}, K_0 \subseteq A, \) and \( K = \text{span}(K_0) \). Topology \( \tau \) is weak topology, \( \pi: C \longrightarrow R \) is a strictly positive linear functional, and \((C, \pi)\) is s-no-arbitrage; if \( x \in K \cap C \), then \( \pi(x) > 0 \).

Theorem 2. The classes of the martingale and the locally martingale coincide on the discrete-time filtrated probability measure.

Proof. Take \( M = (M_t)_{t \in \mathbb{N}} \) as a \( A^n \)-valued local martingale and \( H = (H_t)_{t \in \mathbb{N}} \) as a \( A^n \)-valued predictable process. We define
\[
S = H \cdot M = (\varphi^i, S_t) = \sum_{i=1}^n H^i M^i. \tag{4}
\]

If \( H^i \) is bounded and \( M^i \) is martingale, then \( S \) is martingale.

Otherwise, let \( \{\tau_n\} \) be a sequence of stopping times increasing as to \( \infty \), such that each process \( M^\tau_n \) is a martingale and the process \( S^\tau_n \) is martingale.

Let \( S^\tau_n \) be martingale; that is, \( S^\tau_n \) with the sequence \( \tau_n \) each is integrable and \( E[\tilde{S}_{\tau_{n+1}} | F_n] = E[S^\tau_{n+1} | F_n] \) on the \( F_n \)-measurable set \( \{\tau_n > n\} \).

\[
E[\tilde{S}_{\tau_{n+1}} | F_n] = E[S_{\tau_{n+1}} | F_n] = S^\tau_n \].

Take \( u_n = \sum_{k=0}^{(1/(k+1))} \Delta S^\tau_{n+1} I_{\{u_n \leq |F_n, \varphi_{n+1} \leq 1\}} \) as \( F_n \)-measurable integrable and \( u_n \geq 0 \). Then, \( M_n = \sum_{i=1}^n u_i \) is a martingale, and (4) holds.

Theorem 3. Let \( A \) be ordered Banach algebra with algebra cone \((A, C)\). The s-price system \((C, \pi)\) is s-viable if and only if a character functional \( \psi_{|C} \leq \pi \) exists.

Proof. Suppose there exists a character functional \( \psi_{|C} \leq \pi \); let \( h \in C \) with \( \pi(h) = 0 \). Because \( \psi(h) = \pi(h) \) for all \( h \in H \), then \( \psi(h) = 0 = \psi(0) \). That is, \( \psi(0) \geq \psi(h) \). Hence, \( h \geq e \); that is, \((C, \pi)\) is s-viable.

Conversely, suppose that s-price system is s-viable.

Define \( M = \{h \in A : h > e\}, N = \{h \in C : \pi(h) \leq 0\} \). If \( h \in M \cap N \), then \( h > e \) and \( \pi(h) \leq 0 \); this contradicts that \((C, \pi)\) is s-viable. Then, \( M \) and \( N \) are disjoint.

Because C is cone, then C is a convex set. To prove \( N \) is cone, let \( h_1, h_2 \in C \) and \( 0 \leq \lambda, 0 \leq \beta, \pi(h_1) \leq 0, \pi(h_2) \leq 0; \).
that is, $\lambda \pi(h_1) \leq 0$ and $\beta \pi(h_2) \leq 0$. Then, $\lambda \pi(h_1) + (\beta) \pi(h_2) \leq 0$;
that is, $\pi(h_1 + \beta \pi(h_2) \leq 0$. $\pi$ is character functional; then $h_1 + \beta \pi(h_2) \in C$ and $N$ is cone.

Thus, $M$ and $N$ are disjointed, nonempty convex sets in (OBA). Using the separation theorem, there exists a non-trivial continuous linear functional $\psi$ on $A$ such that $\psi(h) > 0$
for all $h \in M$ and $\psi(h) \leq 0$ for all $h \in N$

If $\psi(h \cdot g) \neq \psi(h) - \psi(g)$, then $\psi(h \cdot g) > \psi(h) - \psi(h \cdot g)$ or $\psi(h \cdot g) < \psi(h) - \psi(g)$.

By taking $h \in M$ and $g \in N$, then $\psi(h), \psi(g) \leq 0$; that is, $\psi(h \cdot g) \leq 0$, to prove $\psi(h) > 0$, $\psi$ is nontrivial, and thus, $x_0 \in A$ exists, such that $\psi(x_0) > 0$.

$M$ is cone and we have $h_0 - \lambda x_0 > 0$ for $\lambda > 0$ and $h_0 \in H$

Therefore, $\psi(h_0 - \lambda x_0) \geq 0$, and by linearity of $\psi$, we have $\psi(m_0 - \lambda \psi(x_0)) \geq 0$, and when $\psi(m_0 \geq \lambda \psi(x_0) > 0$, we get $\psi(h_0) > 0$. As $\pi(h_0) > 0$ and $\psi(h_0) > 0$, $\psi$ can be normalized so that $\psi(h_0) = \pi(h_0)$.

To prove $\psi_M \leq \pi$, let $h \in M$. If $\pi(h) \leq 0$ and $\lambda > 0$ such that $\lambda \pi(h) = 0$, then $\pi((\lambda h + 1)) \leq \pi((\lambda h + 1)) + \pi((\lambda h + 1))h_0 \leq 0$.

For any $\pi(h_0) > 0$, $\psi$ is nontrivial, and thus, $x_0 \in A$ exists, such that $\psi(x_0) > 0$.

**Definition 12.** An s-price is said to be s-no locally free lunch if a net $(m_\alpha, x_\alpha): \alpha \in \Lambda \subseteq \mathbb{C} \times A$ and $x \in X_e$ exist such that

1. $m_\alpha \geq x_\alpha \forall \alpha \in \Lambda$.
2. $x_\alpha \xrightarrow{\delta} x$, and $m_\alpha \xrightarrow{\delta} m$ such that $\pi (m) \leq \delta \forall \alpha \in \Lambda$.

For $\delta \in R$, $m_\alpha \in C$.

**Proposition 1.** The following conditions are equivalent:

1. The s-price system $(C, \pi)$ is no locally free lunch.
2. $\bar{C} \cap X_e \neq \phi$, where $\bar{C}$ is the set of all limit points of convergence net in C

**Proof.** Suppose that $(C, \pi)$ admits an s-locally free lunch. Then, a net $(m_\alpha, x_\alpha): \alpha \in \Lambda \subseteq \mathbb{C} \times A$ and $x \in X_e$ exist such that

1. $m_\alpha \geq x_\alpha \forall \alpha \in \Lambda$.
2. $x_\alpha \xrightarrow{\delta} x$ and $m_\alpha \xrightarrow{\delta} m$ such that $\pi (m) \leq \delta$ for all $\alpha \in \Lambda$ and for $\delta \in \mathbb{R}$.

Then, $m_\alpha \in C$ because $m_\alpha \geq x_\alpha$, and $x_\alpha - m_\alpha \in C$ for all $\alpha \in \Lambda$.

$x_\alpha \xrightarrow{\delta} x$ and $m_\alpha \xrightarrow{\delta} m$, and then, $x - m \in C$; we have $x \geq 0$, that is, $x \in \bar{C}$.

$x \in X_e$ and $x \geq e$ and $x \geq m$; we obtain $m \geq e$, which implies that $m \in m \in \bar{C} \cap m \in X_e$.

Hence, $m \in \bar{C} \cap X_e$; that is, $\bar{C} \cap X_e \neq \phi$.

Conversely, suppose $\bar{C} \cap X_e \neq \phi$. Then, $y \in \bar{C} \cap X_e$ exists, that is, $y \in \bar{C}$ and $y \in X_e$.

$x_\alpha \in C$ such that $x_\alpha \xrightarrow{\delta} y$ and $m_\alpha \in C$ such that $x_\alpha \geq m_\alpha$ for all $\alpha \in \Lambda$, $m_\alpha \in C$ and $\pi (m) \leq \delta$, for all $\alpha \in \Lambda$.

**Theorem 4.** If no locally free lunch exists, then a one-to-one correspondence between the equivalent martingale measure $Q$ for the deflator process and the subcharacter $\varphi \in \Gamma$ exists such that $\varphi_{I_C} = \pi$. This correspondence is given by $Q(\Lambda) = \varphi(I_\Lambda)$ and $\varphi(x) = E_Q(x)$.

**Proof.** Let $Q$ be an equivalent measure; set $\rho = (dQ/dP)$.

Define $\psi: X \rightarrow R$ by $\psi(x) = E_Q(x)$ for all $x \in X$. Then, $\psi(x) = E(Q(x))$ and $\rho \in L^2$; $\psi$ is linear functional and continuous:

$$\psi(x \cdot y) = E_Q(x \cdot y) = E_Q(x) \cdot E_Q(y) = \psi(x) \cdot \psi(y).$$

(5)

Then, $\psi$ is character. $Q \sim P$ and $\rho$ are strictly positive, and thus, $\psi$ is strictly positive.

Take $\varphi = \psi$, that is, $\varphi \in \Gamma$; this remains to show that $\varphi_{|I_C} = \pi$.

For $n = 1, 2, \ldots, k$, we have $E_Q(\langle \theta(t_n), \bar{S}(t_n) \rangle / F_{t_{n-1}}) = E_Q(\langle \theta(t_{n-1}), \bar{S}(t_n) \rangle / F_{t_{n-1}})$:

$$E_Q(\langle \theta(t_n), \bar{S}(t_n) \rangle / F_{t_{n-1}}) = E_Q(\langle \theta(t_{n-1}), \bar{S}(t_n) \rangle / F_{t_{n-1}})$$

(6)

Because $\bar{S}$ is a martingale with respect to $Q$, this equality yields $E_Q(\langle \theta(T), \bar{S}(T) \rangle) = 0$. $V^\psi(T) = h$; that is, $\langle \theta(T), \bar{S}(T) \rangle = h$; then, $E_Q(h) = E(Q(0), \bar{S}(0))$. $\pi(h) = V^\psi(0) = (\langle \theta(0), \bar{S}(0) \rangle)$, and thus $E_Q(h) = \pi(h)$, $\psi(h) = \pi(h)$ for all $m \in C$.

Conversely, let $\varphi \in \Gamma$ such that $\varphi_{|M} = \pi$. Define $Q: F \rightarrow R$ by $Q(X) = \varphi(I_X)$ for all $X \in F$.

If $P(X) = 0$, that is, $I_X = 0$, then $Q(X) = \varphi(0) = 0$.

If $P(X) > 0$, then $I_X \in H_e$. Therefore, $\varphi(I_X) > 0$, that is, $Q(X) > 0$.

To prove that $Q$ is measure $Q(\phi) = \varphi(I_\phi) = 0$ and $Q(U_{i=1}^\infty E_i)$, where $E_1 \in F = \varphi(I_{i=1}^\infty E_i) = \varphi(\sum_{i=1}^\infty E_i - \sum_{i=1}^\infty E_i, \sum_{i=1}^\infty E_i)$. Then, $Q(\phi) = \varphi(\sum_{i=1}^\infty E_i) \subseteq \sum_{i=1}^\infty Q(E_i)$, then $Q$ is measure. Also, to prove the measure $Q$ is equivalent to measure $P$.

If $P(X) > 0$, then $I_X$ is positive linear functional, $\varphi(I_X) > 0$; that is, $Q(X) > 0$.

$\varphi$ is continuous, so $Q$ is a $\sigma$-additive measure, and $dQ/dP = \rho$ is square-integrable.

$\varphi_{|I_C} = 1$ if $x \in \Omega$ and 0 if $x \notin \Omega$; then, $\varphi(I_\Omega) = 1$; that is, $Q(\Omega) = 1$. Thus, $Q$ is probability measure equivalent to $P$.

**Proposition 2.** A trading strategy $H$ is self-financing with respect to the deflator process and only if $H$ is self-financing with respect to $S(t)$. 

\[ \]
Proof

\( V_t(H) = V_{t+1}(H), \)

\[
\phi_t^0 S_t^0 + \langle \phi_t^0, S_t^0 \rangle = \phi_{t+1}^0 S_{t+1}^0 + \langle \phi_{t+1}^0, S_{t+1}^0 \rangle, \\
\phi_t^j S_t^j + \sum_{j=1}^{m} \phi_{t+1}^j S_{t+1}^j = \phi_{t+1}^j S_{t+1}^j + \sum_{j=1}^{m} \phi_{t+1}^j S_{t+1}^j.
\]

(7)

For any \( (X(t))_{t \geq 0} \), for all \( t \in \{0, 1, \ldots, T\} \), a sequence of strictly positive random variables exists as follows:

\[
\phi_t^0 (X(t))^{1-S_t^0} + \sum_{j=1}^{m} \phi_t^j (X(t))^{1-S_t^j} = \phi_{t+1}^0 (X(t))^{1-S_{t+1}^0} + \sum_{j=1}^{m} \phi_{t+1}^j (X(t))^{1-S_{t+1}^j}.
\]

(8)

Then, \( H \) is self-financing with respect to the deflator process \( \bar{S} \).

\[ \square \]

4. Relation between Equivalent Locally Martingale Measure and S-No-Arbitrage

In this section, we introduce important results related to the main subject.

Proposition 3. Let \((\Omega, F, P)\) be a probability space. Then, \((C, \pi)\) is s-no-arbitrage if and only if a deflator process exists.

Proof. Suppose \((C, \pi)\) is no-arbitrage. If \(\bar{S} \in K \cap C\), that is, \(\bar{S} > 0\). Also, \(S_0 = 1\). For any process \(X \in M\), the deflator process \(\bar{S}(t) = (S(t)/X(t))\), then, \(\pi(\bar{S}) = E[\bar{S}_0]\).

Conversely, suppose a deflator process exists. This is equivalent to \(\bar{S} \in K\), that is, \(S_0 > 0\). \(X_0 = 1\) and \(\bar{S}_0 = (S_0/X_0) = E[S_0/X_0] = E[\bar{S}_0]\). Then, \(\pi(\bar{S}_0) = S_0 > 0\).

\[ \square \]

Theorem 5. Let \((\Omega, F, P)\) be a probability space. Then, an equivalent locally martingale exists if and only if a uniformly integrable deflator process exists.

Proof. A measure \(Q\) equivalent to \(P\) with Radon–Nikodym derivative \(dQ/dP = Z_t\), is strictly positive and \(E[Z_t] = 1\), for a given sequence \(\{t_n\}\) with finite stopping time \(\nu \in F_{\nu}\), \(F \cap \{t_n > \nu\} \in F_{\nu}\) and \(F_n = F_{\nu_n}\):

\[
E[\chi_F E(\bar{S}_{t_n > \nu}) | F_{\nu_n}] = E[\bar{S}_{t_n > \nu}] = E[F_{\nu_n} E(\bar{S}_{t_n > \nu}) | F_{\nu_n}],
\]

(9)

where \(E[\bar{S}_{t_n > \nu}] = F_{\nu_n}\)-measurable, \(E[\bar{S}_{t_n > \nu}] = E[\bar{S}_{t_n > \nu}] = E[F_{\nu_n} E(\bar{S}_{t_n > \nu}) | F_{\nu_n}]\), and \(Z\bar{S}\) is itself a local martingale.

Then, for any \(S \in M\), \(\pi(S) = E_p(S/X) = E_Q(S)\) and \(\bar{S} = E_p[Z_t], \lim E[Z_t\bar{S}_t] = E[Z_t] = 1\).

Then, \(\bar{S}\) is uniformly integrable.

Conversely, if \(\bar{S}\) is a uniformly integrable deflator process. Then, \(\bar{S} \in K\) and \(E[Z_t] = 1\).

Choose \(Q\) as a probability measure on the space \((\Omega, F)\), equivalent to \(P\); then, with Radon–Nikodym theorem, it becomes \((dQ/dP) = Z_t\), so that \(Q_{t^n} = Q[[\nu]] = Z_t(u)P[u] = Q[[\nu]] = Z_t(u)P[u] = Q[[\nu]]\) for all \(u \in A\).

For any \(S \in M\), \(E_p(S/X) = \pi(\bar{S})\), but \(\pi(\bar{S}) = E_Q(\bar{S})\). Then, \(E_p(S/X) = E_Q(S)\) and the \(P\)-martingale property of \(\bar{S}\) is \(Q\)-martingale property of \(S\).

\[ \square \]

Theorem 6. Let \(S\) be a \(\mathbb{R}^{d+1}\)-valued semimartingale with nonnegative components defined on the filtered probability space \((\Omega, F, \{F_t\}_{t \in T}, P)\). Then, equivalent local martingale measure for deflator process exists.

Proof. Let \(\Theta\) be a set of all nonnegative processes, \(D = [X \in \Theta: X_t > 0]\) and \(\preceq\) be a binary relation on \(\Theta\) defined as

\[
X \preceq Y \text{ iff } X_0 \leq Y_0 \text{ and } X - Y \text{ is a supermartingale.}
\]

(10)

This order is not preferences ordered, if we have \(A\) to the quotient space obtained from \(\Theta\) by identifying processes whose difference is locally martingale null at \(0\); the pair \((A, \preceq)\) is an ordered linear space. Let \(C\) be a set of all \(\bar{X} \in A\) such that \(\bar{X} \leq 1\). Then, the closure \(\overline{C} = \{X \in \Theta: E[X \overline{Y}] \leq 1\forall \overline{Y} \in D\} \). Define \(T: C \rightarrow R\) as follows: \(T(X) = E[X]\) for all \(X \in C\).

Then, \(C \cap A^+ = \emptyset\), because for every \(\bar{X} \in \overline{C}\), we have \(X \leq 0\) for some \(q \in \overline{P}(\bar{X})\); let \(\bar{X} \in A^+\). Then, \(\bar{X} \not\in \overline{C}\). But \(C - A^+ \subset C\) implies \(C - A^\circ \subset \overline{C}\). Thus, \(\bar{X} \not\in \overline{C} - A^\circ\). So there exists an open, convex neighborhood of \(\bar{X}\). Say \(N(\bar{X})\), such that \(N(\bar{X}) \cap (C - A^\circ) = \emptyset\). In particular, \(N(\bar{X}) \cap (C - A^\circ) = \emptyset\).

Let \(C(\bar{X})\) denote the convex cone generated by \(N(\bar{X})\) by \(C(\bar{X}) = \{\bar{Y} \in A: \bar{Y} = \lambda \bar{X} \text{ for some } \lambda \geq 0 \text{ and } \bar{X} \in N(\bar{X})\} \). Then, \(C(\bar{X}) \cap (C - A^\circ) = \emptyset\), and by Hahn–Banach theorem, a continuous linear functional \(P: A \rightarrow R\) such that \(P(X) \geq 0\) for every \(\bar{X} \in C(\bar{X}) \) and \(P(X) \leq 0\) for every \(\bar{X} \in C\). Hence, \(\overline{P}: C \rightarrow R\) is a strictly positive character.

For every \(\bar{X} \in C\), \(P(X) \leq 0\) implies \(P(X) \leq 0\) replacing \(m\) with \(\bar{X}\) in this implication.

We see that for every \(\bar{X} \in C\) \(P(X) \geq 0\) and \(P(X) \geq 0\), \(P(X) = 0\) implies \(P(X) = 0 \forall \bar{X} \in C\) and there exists some \(m \in R\) such that \(P(X) = m P(X)\) for every \(\bar{X} \in C\), \(\bar{X} \in C^+\), and \(P(X) > 0\); \(\overline{P}\) is continuous on \(C\). Hence, \(\overline{P}: C \rightarrow R\) is continuous, positive linear functional.

Finally, we show that \(\overline{P}\) is strictly positive. First, assume that \(P\) is not strictly positive. Then, there exists \(X \in C^+\) such that \(P(X) = 0\). Let \(X_{\alpha} = \{\alpha \in V: \bar{X}_{\alpha} \in C\} \subset C\) such that \(X_{\alpha} \rightarrow X\). \(\overline{P}(X_{\alpha}) \rightarrow \overline{P}(X) = 0\). So, \(P(X_{\alpha}) > 0\) for all \(\alpha\) sufficiently large in the directed index set.

Define \(\bar{X}_{\alpha} = X_{\alpha} - \beta_{\alpha} X_{\alpha}\), for every \(\alpha \in \Gamma\) and \(\beta_{\alpha} > 0\) for all \(\alpha\) sufficiently large, and \(\beta_{\alpha} \rightarrow 0\).

Define \(X^\alpha = X_{\alpha} - \beta_{\alpha} X_{\alpha}\) for every \(\gamma \in \Gamma\) and \(X^\alpha \in C\).
Also, \( P(X^*_a) = P(X^*_a - \beta \alpha P(X_0) = 0 \) implies \( X_0 \in \mathcal{C} \), and thus \( X_0 \in \mathcal{C} \cap \mathbb{A}^* \) is a contradiction. \( \mathbb{P} \) is strictly positive. To prove any process under condition is locally martingale, let \( M_0 \) be a set of all measures \( Q \) equivalent to measure \( P \), by taking \( Y^Q = E[(dQ/dP) | F_t] \). \( A_t \) is a non-decreasing, adapted process such that \( A_0 = 0 \), and we assume \( X_0 = 1 \) in \([0, T]\) and find \( H \) to be a predictable \( \mathbb{S} \)integrable process such that \( X = 1 + \int_0^t H_s \mathrm{d}S_s \). We set \( Y_t = (X_t/(X_t - A_t))H_t \), so that \( Y \) is an \( \mathbb{S} \)integrable predictable process:

\[
Y_t = \begin{cases} 0, & v \leq s, \\ Y_s, & v > s. \\ \end{cases}
\]

\[
X_s + \frac{X_s}{X_s - A_s}(X_s - A_s), \quad v > s.
\]

\[
Y^Q_t X_t = Y_t \left( 1 + \int_0^t H_s \mathrm{d}S_s \right) \geq E \left[ Y_s \left( 1 + \int_0^t H_s \mathrm{d}S_s \right) | F_t \right] 
= \frac{X_t}{X_t - A_s} E \left[ Y_s (X_s - A_s) | F_s \right] 
\geq \frac{X_s}{X_s - A_s} E \left[ Y_s (X_s - A_s) | F_s \right].
\]

If we multiply by \((X_s - A_s)/X_s\), we can obtain the desired supermartingale. \( \Box \)

5. Conclusion

In this paper, we use ordered Banach algebra and the algebra cone to define the deflator random variable and confirm that the \( s \)-price system \((\mathcal{C}, \pi)\) is no locally free lunch and equivalent to \( \mathcal{C} \cap \mathcal{X}_s \neq \emptyset \), where \( \mathcal{C} \) is the set of all limit points of convergence net in \( \mathcal{C} \) and the \( s \)-price system \((\mathcal{C}, \pi)\) is s-viable if and only if a subcharacter functional \( \psi|_{\mathcal{C}} \leq \pi \) exists. We validate that the \( s \)-price system \((\mathcal{C}, \pi)\) is no-\( s \)-arbitrage if and only if a deflator process exists and confirm that the trading strategy \( H \) is self-financing with respect to the deflator process if and only if \( H \) is self-financing with respect to \( S(t) \). No locally free lunch is a necessary condition to materialize a one-to-one correspondence between the equivalent martingale measure \( Q \) for the deflator process and the subcharacter \( \varphi \in \Gamma \) such that \( \varphi|_{\mathcal{C}} = \pi \). The uniformly integrable deflator process is also an important condition for generating an equivalent locally martingale measure and to prove that if \( X \) is a \( \mathcal{F} \)-valued semi martingale with nonnegative components defined on the filtered probability space \((\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \in \mathbb{C}} , P)\), we can construct an equivalent local martingale measure for the deflator process.
