ZnO particles with various morphologies were synthesized by mixing ZnSO\textsubscript{4} and NaOH solutions at 25°C followed by aging of the suspensions at 40–80°C for 2.0 h, keeping the initial molar ratio of Zn\textsuperscript{2+} to OH\textsuperscript{−} at 1:4. ZnO irregular plates were prepared by adding NaOH to ZnSO\textsubscript{4} while ε-Zn(OH)\textsubscript{2} rhombic particles were produced using the opposite mixing way. After aging of the slurries at 80°C for 2.0 h, the ZnO plates were kept stable while the ε-Zn(OH)\textsubscript{2} rhombic particles were converted to ZnO whiskers with a length of 1.0–4.0 µm and a diameter of 0.03–0.3 µm. Thermodynamic analysis indicated that the formation of the Zn-bearing precipitates (ZnO or ε-Zn(OH)\textsubscript{2}) at room temperature was connected closely with the solution composition.

1. Introduction

The synthesis of ZnO with varying morphologies such as the multipods [1], the wires [2], the tubes [3], and the flowers [4] via the liquid-phase routes, including the chemical deposition [5], the microemulsion [6], the hydrothermal/solvothermal/sol-gel ways [7–9], the template-assisted method, and so forth [10], has attracted much attention in recent years owing to the moderate condition and the easy control of the properties of the ZnO products. Many former researchers have focused on the influence of surfactants on the morphology control of ZnO. For example, Sun et al. [11] synthesized ZnO nanorods from Zn via the cetyltrimethylammonium-bromide-(CTAB-) assisted route and found that the presence of CTAB promoted the erosion of Zn and the hydrothermal formation of the ZnO nanorods at 180°C. The needle- and flower-like ZnO nanocrystals were fabricated at 85°C by using ZnCl\textsubscript{2} and NaOH as the reactants in the presence of 0.2 mol L\textsuperscript{−1} sodium dodecyl sulfate (SDS) [12]. Some researchers have also studied the influence of the reactants, the solvent, and the pH on the morphology of ZnO. For example, Gao et al. [13] fabricated the rotor-like ZnO at 100°C by treating the suspension containing the rod-like ZnO powders, which were produced from the NH\textsubscript{3}·H\textsubscript{2}O and ZnCl\textsubscript{2} and a saturated Zn(OH)\textsubscript{4}\textsuperscript{2−} solution obtained by dissolving ZnO in 5 mol L\textsuperscript{−1} NaOH. Zheng et al. [14] prepared the porous octahedron- and rod-shaped ZnO architectures from ZnC\textsubscript{2}O\textsubscript{4}·2H\textsubscript{2}O, which was produced by the solvothermal treatment of the mixture of ZnCl\textsubscript{2}, H\textsubscript{2}C\textsubscript{2}O\textsubscript{4}·2H\textsubscript{2}O, N-dimethylformamide (DNF), and methyl orange (MO) at 180°C. Pal et al. [15] synthesized ZnO crystals with granular, flower-like and rod-like morphology by adjusting the pH of the suspension containing Zn(CH\textsubscript{3}COO)\textsubscript{2}·2H\textsubscript{2}O and ethylenediamine (EDA) at 80–100°C.

Herein, a facile precipitation-aging method was developed in this paper to synthesize ZnO nanoparticles and ZnO whiskers simply by changing the mixing of ZnSO\textsubscript{4} and NaOH solutions at room temperature followed by aging of the suspensions at 40–80°C. The influence of the solution composition on the formation of the Zn-bearing precursors and the morphology of the aging products were investigated.

2. Experimental

In a typical procedure, 20 mL of 8.0 mol L\textsuperscript{−1} NaOH was added drop-wise (0.67 mL min\textsuperscript{−1}) into 20 mL of 2.0 mol L\textsuperscript{−1} ZnSO\textsubscript{4} at 25°C, or using the opposite mixing way. The initial molar
ratio of Zn$^{2+}$ to OH$^-$ was 1:4. After being stirred (150 min$^{-1}$) for 1.0 h, the suspension was transferred to a Teflon-lined stainless autoclave with an inner volume of 60 mL and kept under isothermal condition at 80$^\circ$C for 2.0 h. The suspension was then cooled down to room temperature naturally; the precipitate was filtered, washed with deionized water for three times, and dried at 80$^\circ$C for 4.0 h.

The morphology and structure of the samples were characterized by the field-emission scanning electronic microscope (FE-SEM, JOEL 7401F, Japan) and the X-ray powder diffraction (XRD, D8 Advance, Bruker, Germany) using CuKα radiation (λ = 1.5418 Å), respectively. The solution pH was detected by the pH meter (FE20, METTLER-TOLEDO, Germany). The concentrations of soluble Zn$^{2+}$ and OH$^-$ were analyzed by the ethylene diaminetetraacetic acid (EDTA) titration and the acid-base neutralization methods, respectively.

3. Results and Discussion

3.1. Influence of the Mixing Way on the Formation of the Zn-Bearing Precipitates. Figures 1 and 2 show the morphology and the XRD patterns of the Zn-bearing precipitates formed at 25$^\circ$C. Wurtzite ZnO (space group $P6_3mc$, $a = b = 3.250$ Å, $c = 5.207$ Å) irregular plates with a diameter of 0.3–0.6 $\mu$m were prepared if NaOH was added to ZnSO$_4$, while ε-Zn(OH)$_2$ (space group $P2_12_12$, $a = 8.490$ Å, $b = 5.162$ Å, $c = 4.917$ Å) agglomerated octahedral particles with a diameter of 1.0–3.0 $\mu$m were produced if ZnSO$_4$ was added to NaOH.

Figure 3 shows the variation of the total Zn$^{2+}$ concentration ([Zn]$_T$) and the solution pH with the reaction time at 25$^\circ$C. In the case of adding NaOH to ZnSO$_4$ (Figure 3(a)), with the increase of the reaction time from 0 to 60 min, [Zn]$_T$ decreased from 2.0 mol·L$^{-1}$ to 0.08 mol·L$^{-1}$ and the solution pH increased from 3.8 to 12.6; in the case of adding ZnSO$_4$ to NaOH (Figure 3(b)), the increase of the reaction time from 0 to 60 min led to the decrease of [OH$^-$] from 8.0 mol·L$^{-1}$ to 1.4 mol·L$^{-1}$, while the [Zn]$_T$ increased from 0 to 0.36 mol·L$^{-1}$ at the initial 30 min and then decreased gradually to 0.19 mol·L$^{-1}$ as the reaction time increased from 30 min to 60 min.

Table 1 shows the possible equilibrium reactions existed in the ZnSO$_4$-NaOH-H$_2$O system. The equilibrium constants in Table 1 were calculated from the HSC 7.1 software.

Based on the simultaneous equilibrium principle, the equilibrium concentrations of the soluble ions in varying time can be calculated from the knowing concentrations of total soluble Zn$^{2+}$, OH$^-$, Na$^+$, and SO$_4^{2-}$. To simplify the calculation process, the activity of each species was replaced by concentration due to the shortage of the basic data. Based on these equations above and the experimental data in Figure 3, the concentrations of the soluble Zn-bearing species at different reaction time were calculated and the results are shown in Figure 4.

In the case of adding NaOH to ZnSO$_4$ (Figure 4(a)), Zn(OH)$_3(aq)$ was the predominant species and the increase of the reaction time from 10 min to 60 min led to the decrease of [Zn$^{2+}$] and [Zn(OH)$^-$] and the increase of [Zn(OH)$_2$$^{2-}$], [HZnO$_2$$^{2-}$], [Zn(OH)$_4$$^{2-}$], and [ZnO$_2$$^{2-}$]. In the case of adding ZnSO$_4$ to NaOH (Figure 4(b)), all of the Zn-bearing species were kept quite stable within 60 min, and the order of concentrations for these species was [Zn(OH)$_4$$^{2-}$] ≈ [ZnO$_2$$^{2-}$] > [Zn(OH)$_3$$^{-}$] = [HZnO$_2$$^{2-}$] > [Zn(OH)$_2$]$^{2+}$] > [ZnOH$^+$] > [Zn$^{2+}$]. The difference in the solution composition may be one of the major reasons for the formation of different precipitates (ZnO and ε-Zn(OH)$_2$).

3.2. Aging of the ZnO and ε-Zn(OH)$_2$ Precipitates. The morphology and the XRD patterns of the aging products formed from ZnO and ε-Zn(OH)$_2$ precursors were shown in Figures 5 and 6, respectively. Irregular ZnO plates with a similar morphology using the ZnO precursor were formed after aging treatment at 40–80$^\circ$C, indicating that ZnO precursor was quite stable under the experimental conditions. In the case of the ε-Zn(OH)$_2$ precursor, the precursor was stable up to 40$^\circ$C, but changed...
to ZnO rods with a length of 0.1–0.4 μm and a diameter of 40–100 nm and ZnO whiskers with a length of 1.0–14.0 μm and a diameter of 0.03–0.3 μm after aging treatment at 60°C and 80°C, respectively. The different aging behaviors of ZnO and ε-Zn(OH)$_2$ precursors may be connected with their different dissolution abilities in NaOH solution.

Figure 7 shows the dissolution of ZnO and ε-Zn(OH)$_2$ after mixing excessive amount (3.500 g) of ZnO or ε-Zn(OH)$_2$ with 25 mL of 8.0 mol·L$^{-1}$ NaOH at 25–80°C for 2.0 h. The increase of temperature from 25°C to 80°C favored the dissolution of ZnO and ε-Zn(OH)$_2$ in NaOH solution. Compared with ZnO, ε-Zn(OH)$_2$ was more soluble, which favored the formation of ZnO whiskers via the dissolution-precipitation route [16]:

ε-Zn(OH)$_2$ $\overset{\text{dissolution}}{\longrightarrow}$ Zn$^{2+}$ + 2OH$^-$

ε-Zn(OH)$_2$ $\overset{\text{precipitation}}{\longrightarrow}$ ZnO$\_w$ + H$_2$O

4. Conclusions

ZnO particles and whiskers were synthesized by changing the mixing ways of ZnSO₄ and NaOH at room temperature followed by aging of the suspensions at 40–80°C for 2.0 h. Irregular ZnO plates were formed by adding NaOH to ZnSO₄ while ε-Zn(OH)₂ rhombic particles were produced using the opposite mixing way. Thermodynamic analysis indicated that the formation of ZnO and ε-Zn(OH)₂ in different mixing ways of ZnSO₄ and NaOH should be attributed to the different solution compositions. The aging of the slurries containing ε-Zn(OH)₂ and NaOH at 80°C for 2.0 h led to the formation of ZnO whiskers with a length of 1.0–4.0 μm and a diameter of 0.03–0.3 μm owing to the easy dissolving of...
