1. Introduction

The behavior of lanthanides and actinides has received much attention in nuclear waste management [1, 2]. Eu(III) is a trivalent lanthanide ion, and it is also a trivalent actinide chemical element homologue. A large number of Eu(III) exposure in the environment can cause great harm to people’s health and life. Thus, the adsorption and migration of Eu(III) on metal oxides and minerals have been studied extensively, and the investigations of their potential pollution towards the natural water and soil environment are of great importance. Xu et al. studied the adsorption of Eu(III) on TiO$_2$ with the presence of organic matters in different pH values, which indicated its adsorption behavior strongly influenced by the pH changes, and the adsorption mechanism was attributed to the formation of the inner ring complexes [3]. Wang et al. studied the adsorption of Eu(III) on alumina, which was also influenced by the pH changes, and the reaction is a surface complexation reaction [4]. Li et al. studied the adsorption of Eu(III) on iron oxides; the adsorption of Eu(III) was significantly dependent on pH, temperature, and HA [5].

The carbon nanotube is a kind of carbon allotrope with typical layered hollow structure, and it is considered to be a typical one-dimensional material. Multiwalled carbon nanotubes (MWCNTs) are the coaxial tubes formed by several layers to dozens by hexagonal array of carbon atoms, with hybridization of carbon atoms in the tube wall, which can be easily modified; in addition, the carbon atoms exist as $sp^2$ hybridization in the carbon nanotubes and form the most stable chemical bond C=C covalent bond in nature [6]. Therefore, carbon nanotubes have excellent physiochemical property and versatile applications, especially in mechanics, electromagnetism, optics, electronics, catalysis, and composite materials fields, and have huge potential research value [7]. Due to its special structure, carbon nanotubes have large specific surface area and high chemical stability, and their surfaces can be functionalized easily [8], it is widely used in the adsorption process. Some researchers have done the study about metal ions (Pb(II), Ni(II), and Cd(II)) adsorbed onto MWCNTs in detail [9–11]. For example, Deng et al. studied the adsorption mechanism of PFCs (perfluorinated compounds) on MWCNTs [12]; their results indicated that...
MWCNTs have extremely excellent adsorption properties. And Sheng et al. [13] studied the adsorption of Eu(III) onto titanate nanotubes in microscopic insights.

Compared with experimental environment, the natural environment is more complicated [14]. There are few studies about the behavior of other organic materials on the adsorption of metal ions in the presence of carbon nanomaterials. Therefore, it is of great significance to study the effects of a variety of carbon nanomaterials coexisting on the adsorption of metal ions. In order to simulate the interactions of carbon nanomaterials with metal ions in a real environment, the organic matters are often selected as another study factors in the ternary system to study the adsorption of metal ions [15–19]. In our study, the water-soluble fullerenes was selected as the third element of the adsorption system to study its effect on Eu(III) adsorbed onto carbon nanotubes.

The fullerenes are following graphite, diamond, amorphous carbon, and another allotropes of carbon, which has broad applications in the gas storage, the field of optics, the polymer field, enhanced metals, superconducting field, battery materials, catalysts, and biological medical prospects [20]. As a fullerene, C_{60} is the cheapest and easiest to obtain, so C_{60} and its derivatives were used to investigate their properties in the current studies. Due to their large number of \( \pi \) electrons, fullerene is very easy to form \( \pi - \pi \) stacking with other aromatic materials [21, 22], then to affect its adsorption on metal ion or an organic. And adding the appropriate functional groups to the fullerene skeleton can improve the poor solubility [23]. Therefore, studying the effect of water-soluble fullerene on adsorption of Eu(III) onto carbon nanotubes can provide a new method for the study of trivalent lanthanides and actinides behavior, explore a variety of factors, and provide a theoretical basis for the long-lived radioactive waste disposal security issues.

2. Materials and Methods

2.1. Materials. Multiwall carbon nanotubes (L. MWNTs-1030) materials, purity > 95% (amorphous carbon ≤ 3 wt%, ash content ≤ 0.2 wt%), with a diameter of 10–30 nm, the length of 1–10 \( \mu \)m, specific surface area of 10–100 m\(^2\)/g, were purchased from Shenzhen Nanotech Port Company. Oxidation multi-walled carbon nanotubes were made by raw carbon nanotubes and concentrated nitric acid. First, 3 g MWCNTs were added into concentrated nitric acid (400 mL). The mixture was stirred at 80 \( ^\circ \)C for 24 h then quenched with deionized water, and the product was collected. A mixture of concentrated nitric acid and concentrated sulfuric acid (1:3, V/V) (400 mL) was added to the above compound and refluxed for 48 h then washed with deionized water (pH \( \approx \) 6) to gain the oxidation multi-walled carbon nanotubes (oxidized MWCNTs, oMWCNTs) [26].

Fullerene (C_{60}), purity > 99.9%, was purchased from Yongxin the fullerene Technology Co. Ltd. of Puyang City, Henan Province. The C_{60} and NaH were added into toluene, when the color of the mixture solution changed from purple to deep red, then added diethyl bromomalonate. The residue was dissolved in the toluene, and then added NaH (excess 20-fold than before). The solution was stirred at 80 \( ^\circ \)C for 10 h under the protection of Ar gas and heating. Then, C_{60}OH was added to the solution to terminate the reaction immediately, and added 2 mol/L HCl. The precipitate was filtered, collected, and washed by toluene, 2 mol/L HCl, H_{2}O, and benzene [29].

Unless otherwise noted, materials were obtained from commercial suppliers and were used without further purification.

2.2. Batch Experiments. Determining the equilibrium time and the solid-liquid ratio, in a series of polyethylene centrifuge tube added a certain amount of oMWCNTs, NaCl and a known concentration EuCl\(_3\) solution, so that the various components of the system achieved the required concentration. The extremely small amount of HCl or NaOH solution can be added to the system to adjust the pH to a desired value. The samples were centrifuged 30 min at 12000 r/min after shaking 72 h in constant temperature. Taking out a certain volume supernatant, the supernatant counts were measured by a liquid scintillation counter. The adsorption of Eu(III) on the oMWCNTs was calculated by before and after the adsorption of Eu(III) in the liquid phase concentration.

2.3. X-Ray Photoelectron Spectroscopy (XPS) Analysis. In order to further analyze the molecular level information of the adsorbent material; the thermoelectric ESCALAB 250 spectrometer was used to identify the property of adsorbent material, the results were shown in Figure 1. The Cls peaks of oMWCNTs samples were at about 285.0, 288.2, and 289.0 eV (Figure 1(a)), which were corresponding the C–C, CO, and COO, respectively [30]. And O1s peaks of oMWCNTs sample at about 532.1, 534.1, and 537.2 eV (Figure 1(b)) were indicated the OH, OH/CO, and COO/H\(_2\)O, respectively [31]. Cls peaks of C\(_{60}\)(OH)\(_n\) at about 285.0 and 286.98 eV (Figure 1(c)) showed the C–C and COO, respectively Ols peak of C\(_{60}\)(OH)\(_n\) at 532.77 eV (Figure 1(d)) was assigned to bridging OH. Cls peak of C\(_{60}\)(C(OH)\(_2\))\(_m\) at about 284.9 and 289.1 eV (Figure 1(e)) was corresponding the C–C and COO, respectively. Ols peak of C\(_{60}\)(C(OH)\(_2\))\(_m\) at about 532.4 and 533.5 eV (Figure 1(f)) could be assigned to bridging OH and COO/H\(_2\)O, respectively. The related peak areas are shown in Table 1.

3. Results and Discussions

3.1. Adsorption Kinetics

3.1.1. Effect of Equilibrium Time on Eu(III) Adsorption onto oMWCNTs. The influence of the shaking time on Eu(III) adsorption onto oMWCNTs is shown in Figure 2. The adsorption ratio was increased with the increase of the shaking time. After 17 h, the adsorption ratio of Eu(III) was close to 100%; after that it was substantially unchanged. These results indicated that the adsorption of Eu(III) onto oMWCNTs was a chemical adsorption process [10]. The 48 h was selected as the equilibrium time in the following experiments.

3.1.2. Pseudo-Second-Order Equation. Quasi-second-order kinetic equation linear expression is

\[ \frac{t}{q_t} = \frac{1}{kq_e^2} + \frac{t}{q_e}, \]  

where \( q_t \) and \( q_e \) denote the time \( t \) and the equilibrium adsorption amount (mg/g) and \( k \) is the second-order rate
Figure 2: Effect of equilibrium time on Eu(III) adsorption onto oMWCNTs. pH = 3.00 ± 0.05, \( m/V = 0.0250 \, \text{g/L} \), \( T = (25 \pm 1) ^\circ \text{C} \), \( C_{0_{\text{Eu}}} = 1.21 \times 10^{-5} \, \text{mol/L} \).

Figure 3: Pseudo-second-order sorption kinetics plot for Eu(III). pH = 3.00 ± 0.05, \( m/V = 0.0250 \, \text{g/L} \), \( T = (25 \pm 1) ^\circ \text{C} \), \( C_{0_{\text{Eu}}} = 1.21 \times 10^{-5} \, \text{mol/L} \).

Figure 4: Effect of pH on Eu(III) adsorption onto oMWCNTs. \( m/V = 0.0250 \, \text{g/L} \), \( T = (25 \pm 1) ^\circ \text{C} \), \( C_{0_{\text{Eu}}} = 1.21 \times 10^{-5} \, \text{mol/L} \).

Figure 5: Relative species distribution of Eu(III). \( T = (25 \pm 1) ^\circ \text{C} \), \( C_{0_{\text{Eu}}} = 1.21 \times 10^{-5} \, \text{mol/L} \), \( P_{\text{CO}_2} = 0.0038 \).

Figure 6: Effect of solid-to-liquid ratio of Eu(III) adsorption onto oMWCNTs. pH = 3.00 ± 0.05, \( m/V = 0.0250 \, \text{g/L} \), \( T = (25 \pm 1) ^\circ \text{C} \), \( C_{0_{\text{Eu}}} = 1.21 \times 10^{-5} \, \text{mol/L} \).

3.2. Effect of pH on Eu(III) Adsorption onto oMWCNTs.

The influence of different pH on the adsorption was shown in Figure 4. Figure 4 shows that when the solid-liquid is 0.025 g/L and ionic strength is 0.1 mol/L (NaCl), the ratio of Eu(III) adsorption onto oMWCNTs is influenced strongly by the pH. Figure 4 also shows the adsorption ratio of Eu(III) onto oMWCNTs declines with the ionic strength increases, suggesting that the adsorption can be suppressed by ionic constant \((g \cdot mg^{-1} \cdot min^{-1})\). Using this equation to fit the experimental data, the results as shown in Figure 3, quasi-second-order equation is \( y = 0.00013x + 0.00552 \), calculated by the slope and intercept of \( k = 3.3214 \times 10^{-3} \, \text{g/mg \cdot min} \), the \( q_e = 0.7757 \, \text{mg/g} \) and the linear correlation coefficient \( R^2 = 0.9996 \) which is almost 1. These results showed that the adsorption of Eu(III) onto oMWCNTs was keeping with the quasi-second-order kinetic model.

4. Journal of Nanomaterials
strength. Sheng et al. found that the adsorption rate of Th(IV) on raw diatomite increased rapidly to about 100% when the pH value changed from 2 to 4 and was influenced by the ionic strength strongly [13]. Wu et al., Guo et al., and Mingming et al. also found that the adsorption of Eu(III) on sodium bentonite and Na-attapulgite was effected by ionic strength and pH changes strongly [32–34]. The experimental results in this work further confirmed the previous results.

When pH < 1.5, the adsorption ratio was low and almost not changing with the pH increased. In the range pH of 1.5 to 4.0, the adsorption ratio increased rapidly, from 20% to about 90%. When pH > 4.0, the adsorption ratio changed not so obviously indicating that the system was in equilibrium. Because the species distribution of Eu(III) can form a water-soluble carbonates at high pH, so the adsorption ratio cannot reach 100%.

The effect of pH on Eu(III) adsorption onto the oMWCNTs could be explained by the surface charge and ionization degree of oMWCNTs. When pH < pH_{pzc}, Eu^{3+} and oMWCNTs surface proton produces electrostatic repulsion, which prevents Eu^{3+} from being adsorbed onto oMWCNTs, resulting in a lower adsorption ratio of Eu(III). When pH > pH_{pzc}, Eu^{3+} interacts with oMWCNTs surface proton by electrostatic attraction making more Eu(III) adsorbed onto oMWCNTs surface, increasing the adsorption ratio of Eu(III). The species changes of Eu(III) with pH in solution is another important influencing factor for the adsorption system. The thermodynamic data used to estimate the Eu(III) species distribution in the solution were listed in Table 2. As shown in Figure 5, when the initial concentration of Eu(III) is $1.21 \times 10^{-5}$ mol/L with background electrolyte (0.01 mol/L NaCl solution), the main existence forms are Eu^{3+}, Eu(OH)$_2^+$, EuCl$_2^+$, EuCO$_3^+$, Eu(CO$_3$)$_2^{-}$. When pH ≤ 6.5, the main species is Eu$^{3+}$. When pH > 6.5, due to the impact of CO$_2$, Eu(III) mainly exists as the forms of EuCO$_3^+$ and Eu(CO$_3$)$_2^{-}$ in solution, which have relatively low solubility in aqueous solution leading to increase Eu(III) content in the solid phase, so the adsorption ratio of Eu(III) onto oMWCNTs maintains the maximum and no longer changes.

3.3. Effect of Solid-Liquid Ratio on Eu(III) Adsorption onto oMWCNTs. Figure 6 shows that the adsorption ratio transformation of Eu(III) adsorption onto oMWCNTs increases.
with the increasing of oMWCNTs concentration. With the increasing of the solid solution ratio in the system, the adsorption ratio of Eu(III) is increasing until Eu(III) is adsorbed completely. While the percentage composition of oMWCNTs increases, the surface adsorption sites also increase, which can promote the adsorption of Eu(III). Figure 6 also shows the influence of different m/V value on the distribution coefficient $K_d$. $K_d$ values can be estimated by $C_s$ and $C_e$:

$$K_d = \frac{C_s - C_e}{C_e} \cdot \frac{V}{m},$$

(2)

where $V$ is the volume of the solution (m/L) and $m$ is the weight of solid (g). As shown in Figure 6, with the increasing of the solid-liquid ratio, $K_d$ values also increase gradually, when the solid-liquid ratio exceeds 0.1 mL/g, $K_d$ value declines slightly. Thus, it can be seen from that, $K_d$ value depends on the solid content at low solid concentration, but when the solid content reaches a certain concentration, $K_d$ value is never depend on the solid content. This phenomenon also presents in the adsorption system of the other metal ions and the different adsorbents [35, 36].

### 3.4. Effect of $C_{60}(OH)_n$ on Eu(III) Adsorption onto oMWCNTs

Figure 7 shows the Eu(III) adsorption border changes in the present of different $C_{60}(OH)_n$ concentration. When the concentration of $C_{60}(OH)_n$ is 250 mg/L, the adsorption capacity of Eu(III) on the oMWCNTs is about 10% at pH 2.5, but it arrives at about 28% at pH 7. While the concentration of $C_{60}(OH)_n$ is 125 mg/L, the adsorption rate increases significantly, which rises from 20% at pH 2.5 to 38% at pH 6.8. Similarly, when the concentration of $C_{60}(OH)_n$ is 45 mg/L, the adsorption of $C_{60}(OH)_n$ reaches the maximum at the same pH value. These results show that the presence of $C_{60}(OH)_n$ can restrain the adsorption of Eu(III) onto oMWCNTs. According to the literatures, in a ternary system, the organic material plays an important role in metal ions adsorbed onto oMWCNTs. It is mainly attributed to the ternary complex which was formed by metal ion, the organics, and the surface functional groups of oMWCNTs through hydrophobic interactions, electrostatic interactions, and hydrogen bonds [37, 38]. But $C_{60}(OH)_n$ can compete with Eu(III) for the surface adsorption sites of oMWCNTs, which could weaken the adsorption ratio of Eu(III) onto oMWCNTs. With the concentration of $C_{60}(OH)_n$ increasing gradually, more and more $C_{60}(OH)_n$ is connected to oMWCNTs. So $C_{60}(OH)_n$ could affect the surface properties of oMWCNTs as well as the adsorption sites, then the adsorption ratio of Eu(III) onto oMWCNTs is decreased. For further understanding of the effect of $C_{60}(OH)_n$ on the adsorption system, changing the initial concentration of Eu(III) and solid-liquid ratio to observe

**Figure 10:** Effect of $C_{60}(OH)_n$ on the adsorption of Eu(III) onto oMWCNTs. pH = 3.00 ± 0.05, $m/V = 0.025$ g/L, $T = (25 \pm 1)^{\circ}$C, $C_{Eu} = 1.21 \times 10^{-5}$ mol/L.

**Figure 11:** Effect of Eu(III) initial concentrations and $C_{60}(C(COOH)_2)_n$ concentrations on Eu(III) adsorption onto oMWCNTs. pH = 3.00 ± 0.05, $m/V = 0.025$ g/L, $T = (25 \pm 1)^{\circ}$C, $C_{Eu} = 1.21 \times 10^{-5}$ mol/L.
the effects of different $C_{co}(OH)_n$ concentrations on Eu(III) adsorption onto oMWCNTs was investigated (Figures 8 and 9). It indicates that the Eu(III) is only adsorbed on oMWCNTs surface with no interaction with $C_{co}(OH)_n$. As shown in Figure 8, when the initial concentration of Eu(III) is $6.0822 \times 10^{-5}$ mol/L, the adsorption rate becomes smaller gradually with $C_{co}(OH)_n$ concentration increases. The result shows that Eu(III) is adsorbed by oMWCNTs before the interaction of oMWCNTs with $C_{co}(OH)_n$ due to the low concentration of Eu(III), Conversely, when the initial concentration of the Eu(III) is increased to $2.3082 \times 10^{-5}$ mol/L, under the same concentration of oMWCNTs and $C_{co}(OH)_n$, the adsorption ratio is increases gradually because the abundant Eu(III) is enough strong to compete with $C_{co}(OH)_n$ for oMWCNTs. Figure 9 shows that when the solid-liquid ratio is 0.0250 g/L or 0.0083 g/L, and the concentration of $C_{co}(OH)_n$ is less than 150 mg/L, the adsorption ratio of Eu(III) declines sharply, and then with the increasing of $C_{co}(OH)_n$, the adsorption rate becomes slow and till to stable. However, when the solid-liquid ratio rises to 0.0500 g/L, the adsorption rate of Eu(III) is slowly decreased, but it is higher than that of the solid-liquid ratio is 0.0250 g/L and 0.0083 g/L. This is because that with the increasing of solid-liquid ratio, the available adsorption sites also increases, so more Eu(III) is adsorbed to oMWCNTs.

3.5. Effect of $C_{co}(C(COOH)_2)_2$ on Eu(III) Adsorption onto oMWCNTs. The effect of $C_{co}(C(COOH)_2)_2$ on the adsorption of Eu(III) is shown in Figure 10. The presence of $C_{co}(C(COOH)_2)_2$ promoted the adsorption of the Eu(III) onto the oMWCNTs in the pH range of 1.5 to 3.5 significantly, and the maximum adsorption ratio is observed at pH $> 3.5$. Considering the ability of $\pi-\pi$ stacking between $C_{co}(C(COOH)_2)_2$ and oMWCNTs is less than that of $C_{co}(OH)_n$, and the space steric effect of $C_{co}(C(COOH)_2)_2$ is stronger than that of $C_{co}(OH)_n$, so the adsorption capacity of $C_{co}(C(COOH)_2)_2$ onto the surface of oMWCNTs is not as large as $C_{co}(OH)_n$, which provides more opportunities for Eu(III) to be adsorbed by oMWCNTs. Under the acidic environment, $C_{co}(C(COOH)_2)_2$ is very easy to combine with $H^+$ from the solution and oMWCNTs surface, so Eu(III) is adsorbed onto the surface of oMWCNTs more easily. Meanwhile, the presence of hydrolyzate of Eu(III) may also be another reason to increase the adsorption ratio.

Similarly, changing the initial concentration of Eu(III) and the ratio of solid to liquid at pH 3.00 ± 0.05, the effect of $C_{co}(C(COOH)_2)_2$ concentration on the adsorption ratio is shown in Figures 11 and 12. As shown in Figure 11, when the initial concentration of Eu(III) is $6.0822 \times 10^{-6}$ g/L, there are enough adsorption sites to be occupied by Eu(III), and the adsorption ratio can reach maximum value fast. However, when the initial concentration of Eu(III) is $2.3082 \times 10^{-7}$ g/L, the adsorption sites of oMWCNTs are occupied completely at absence of $C_{co}(C(COOH)_2)_2$, and the adsorption ratio is low; but once the $C_{co}(C(COOH)_2)_2$ is added, the $C_{co}(C(COOH)_2)_2$ can improve Eu(III) adsorption onto oMWCNTs, thus the adsorption ratio is increased with the increasing of $C_{co}(C(COOH)_2)_2$ concentration until to the maximum, and then maintains this level. As shown in Figure 12, for the low solid-liquid ratio, such as $m/V = 0.0083$ g/L or 0.0250 g/L, the quantity of Eu(III) in the solution are so much more than the adsorption sites of oMWCNTs. After the adsorption process is in the equilibrium at the experimental conditions, the solid-liquid ratio is low, and the sorption ratio also is low. However, when the $C_{co}(C(COOH)_2)_2$ presents at the adsorption system, the adsorption ratio is increased due to $C_{co}(C(COOH)_2)_2$ can promote the adsorption of Eu(III) onto oMWCNTs. And with the increasing of the concentration of $C_{co}(C(COOH)_2)_2$, the adsorption ratio is increased till the Eu(III) adsorbed completely.

4. Conclusion

The effects and behavior of Eu(III) adsorption onto oMWCNTs are studied when the $C_{co}(C(COOH)_2)_2$ or $C_{co}(OH)_n$ is added. The adsorption of Eu(III) onto oMWCNTs is affected strongly by pH and ionic strength. The presence of $C_{co}(C(COOH)_2)_2$ promotes the changes of adsorption ratio obviously. However, $C_{co}(OH)_n$ competes the adsorption sites with Eu(III), leading to reducing the adsorption ratio of Eu(III) adsorbed onto oMWCNTs.
