An obstacle avoidance method of action support 7-DOF manipulators is proposed in this paper. The manipulators are controlled with impedance control to follow user’s motions. 7-DOF manipulators are able to avoid obstacles without changing the orbit of the end-effector because they have kinematic redundancy. A joint rate vector is used to change angular velocity of an arbitrary joint with kinematic redundancy. The priority of avoidance is introduced into the proposed method, so that avoidance motions precede follow motions when obstacles are close to the manipulators. The usefulness of the proposed method is demonstrated through obstacle avoidance simulations and experiments.

1. Introduction

The application of robot technology extends from the manufacturing industry to our homes. In particular, applied research on robot technology is widely carried out in the field of medical treatment and welfare, such as operation support robots and meal support robots. The authors focus on an action support manipulator which supports humans with poor muscle strength. One application of this manipulator is a meal support manipulator. The manipulator grasps a spoon, and a user attaches the hand to the spoon. The spoon moves to the desired direction according to the minute force applied by the user. Obstacle avoidance is necessary to use the manipulator safely under the environment where humans and other objects exist.

A 7-DOF manipulator is used as an action support in this paper. 7-DOF manipulators have kinematic redundancy. 7-DOF manipulators are able to avoid obstacles without changing the position and the attitude of the end-effector by using their redundant degree of freedom. Various methods on obstacle avoidance for redundant manipulators are proposed in [1–6]. A joint rate vector [1, 2] is adopted to avoid obstacles in this paper.

Impedance control [7–10] is used to make the manipulator follow the user’s motion in this paper. Though the methods of impedance control for redundant manipulators are proposed in [7, 8], the obstacle avoidance is not handled. The methods of impedance control for redundant manipulators considering the obstacle avoidance are presented in [9, 10]. Though the manipulator avoids the obstacle while the end-effector follows the fixed reference path in [9, 10], cooperative works of manipulators and humans are not considered.

An obstacle avoidance method for redundant manipulators using impedance control is proposed in this paper. Priority of avoidance is introduced into the proposed method, so that avoidance motions precede follow motions when an obstacle is close to the manipulator. There are few papers on obstacle avoidance by using the joint rate vector for redundant manipulators which follows the human’s actions with impedance control. The validity of the proposed method is demonstrated through obstacle avoidance simulations and experiments.

2. Experimental Equipment

Figure 1 shows a manipulator used in this paper. This manipulator is the PA-10A-ARM made by Mitsubishi Heavy Industries, Ltd. The manipulator has seven degrees of freedom and the transportable weight is 98 N. The joints are driven by
AC servo motors with brushless resolvers. The manipulator moves to support a user (see Figure 2).

A force sensor is installed in the end-effector to measure forces and moments applied to the end-effector. The force sensor is the IFS-67M25A50-I40 made by Nitta Corp. The measurable maximum forces are 200 N on x- and y-axis and 400 N on z-axis, and the measurable maximum moment is 13 Nm around x-, y- and z-axis.

The distance between obstacles and the manipulator may be measured with a distance sensor such as a PSD sensor, a laser sensor, an ultrasonic sensor, or a stereo camera. The distance is calculated under the situation that obstacles’ sizes and positions are known in this paper. This ideal situation is considered in experiment to evaluate the proposed method purely, because the experimental performance is too sensitive to the accuracy of the distance sensor.

The seven joint angles of the manipulator and the output of the force sensor are transmitted to a personal computer. The command calculated in the computer is sent to the manipulator. The sampling period is 10 ms.

### 3. Obstacle Avoidance Method

The manipulator is controlled with impedance control to follow user’s motions. Kinematic redundancy is used to avoid obstacles. Priority of avoidance is introduced to combine the follow motions and the avoidance motions.

#### 3.1. Impedance Control

The motion equation of the manipulator is expressed as

\[
M(\theta) \ddot{\theta} + h(\theta, \dot{\theta}) + g(\theta) = \tau + J^T(\theta) F_{\text{ext}},
\]

where \( \theta = [\theta_1, \theta_2, \theta_3, \theta_4, \theta_5, \theta_6, \theta_7]^T \) is the joint angle vector; \( M(\theta) \) is the inertia matrix (hereafter denoted by \( M \)); \( h(\theta, \dot{\theta}) \) is the nonlinear term due to the centrifugal and Coriolis force; \( g(\theta) \) is the gravitational term; \( \tau \) is the joint torque vector; \( F_{\text{ext}} \) is the external force exerted to the end-effector; and \( J(\theta) \) is the Jacobian matrix (hereafter denoted by \( J \)).

The desired impedance of the end-effector is described by

\[
M_e \ddot{x} + B_e \dot{x} + K_e (x - x_d) = F_{\text{ext}},
\]

where \( M_e, B_e, \) and \( K_e \) are the desired inertia, viscosity, and stiffness matrices of the end-effector, respectively; \( x \) is the
displacement vector of the end-effector, and $\mathbf{x}_d$ is the desired one. These are given as follows:

$$
\mathbf{M}_c = \text{diag}(m_c, m_c, m_c, I_m, I_m, I_m),
$$

$$
\mathbf{B}_c = \text{diag}(b_c, b_c, b_c, b_c, b_c, b_c),
$$

$$
\mathbf{K}_c = \text{diag}(k_c, k_c, k_c, k_n, k_n, k_n),
$$

$$
\mathbf{F}_{\text{ext}} = [f_x, f_y, f_z, \tau_\phi, \tau_\theta, \tau_\psi]^T,
$$

$$
\mathbf{x} = [x, y, z, \phi, \theta, \psi]^T.
$$

The position and the attitude of the end-effector are denoted by $(x, y, z)$ and $(\phi, \theta, \psi)$, respectively. The moments $\tau_\phi$, $\tau_\theta$, and $\tau_\psi$ of $\mathbf{F}_{\text{ext}}$ are set to zero to keep the initial attitude of the end-effector in this method. The values of the impedance parameters, $m_c = 1.0$ kg, $I_m = 1.0$ kgm², $b_c = 20$ Ns/m, $b_n = 20$ Nms/rad, $k_c = 100$ N/m, and $k_n = 100$ Nm/rad are used in this paper. These values should be optimized for users in the future work.

Putting $\mathbf{F}_{\text{ext}}$ in (2) as

$$
\mathbf{F}_{\text{ext}} = \mathbf{M}_c \ddot{\mathbf{x}}_d + \mathbf{B}_c \dot{\mathbf{x}}_d,
$$

the following equation is obtained:

$$
\mathbf{M}_c (\ddot{\mathbf{x}} - \ddot{\mathbf{x}}_d) + \mathbf{B}_c (\dot{\mathbf{x}} - \dot{\mathbf{x}}_d) + \mathbf{K}_c (\mathbf{x} - \mathbf{x}_d) = 0.
$$

The torque vector $\mathbf{\tau}$ satisfying (5) is given as follows:

$$
\mathbf{\tau} = \mathbf{J}^T (\mathbf{J} \mathbf{M}^{-1} \mathbf{J}^T)^{-1}
$$

$$
\times \left[ \mathbf{\dot{x}}_d + \mathbf{M}_c^{-1} \left( \mathbf{B}_c (\dot{\mathbf{x}}_d - \mathbf{x}) + \mathbf{K}_c (\mathbf{x}_d - \mathbf{x}) \right) - \mathbf{J} \mathbf{q} \right]
$$

$$
- \mathbf{J}^T \mathbf{F}_{\text{ext}} + \mathbf{h} (\mathbf{\theta}, \dot{\mathbf{\theta}}) + \mathbf{g} (\mathbf{\theta}).
$$
The desired displacement of the end-effector $\mathbf{x}_d$ and its derivative $\dot{\mathbf{x}}_d$ is obtained from $\mathbf{F}_{ext}$ by solving (4) with the 4-order Runge-Kutta method. The value of $\dot{x}_d$ is calculated from $x_d$ by using the backward difference approximation. The end-effector follows the user’s hand by applying the torque $\mathbf{\tau}$ in (6) to the manipulator. The desired displacement $\mathbf{x}_d$ is generated in real time from the external force $\mathbf{F}_{ext}$. This point is greatly different from other studies on impedance control for manipulators.

### 3.2. Obstacle Avoidance Using Kinematic Redundancy.

The inverse kinematics equation of redundant manipulators is expressed as

$$\dot{\mathbf{\theta}} = \mathbf{J}^+ \mathbf{x} + \mathbf{P}^\perp(\mathbf{J}) \mathbf{\xi},$$

where $\mathbf{J}^+$ is the pseudoinverse of $\mathbf{J}$, $\mathbf{P}^\perp(\mathbf{J})$ is the projection operator which projects arbitrary joint rates into the null-space of the end-effector’s Cartesian coordinates, and $\mathbf{\xi}$ is an arbitrary joint rate vector. $\mathbf{J}^+$ and $\mathbf{P}^\perp(\mathbf{J})$ are calculated by the method in [11]. The displacement vector of the end-effector $\mathbf{x}$ is regulated by the impedance control to follow the external force $\mathbf{F}_{ext}$. When an obstacle approaches the manipulator, the manipulator avoids the obstacle by using the joint rate vector $\mathbf{\xi}$.

In this paper, two virtual spheres are set in the 4th and the 5th joints (see Figure 3). The center of the virtual sphere is that of the joint. It is considered that these joints may collide against obstacles easily. The virtual sphere is shown in Figure 4. The inner sphere with the radius $L_{min}$ is an inelastic body and covers the joint of the manipulator. The purpose of the obstacle avoidance control is to avoid the collision between the inner sphere and obstacles. The outer sphere with the radius $L_{max}$ is an elastic body with a stiffness $k_s$. When obstacles enter the outer sphere, a repulsive force is generated. The repulsive force is used to calculate the value of the joint rate vector $\mathbf{\xi}$. 

---

**Figure 9:** Verification of simulation model (2).

**Figure 10:** Obstacle avoidance in simulation.

**Figure 11:** Actual applied force, $\mathbf{F}_{act}$.

**Figure 12:** Distance $d_{min}$ in Cases 1, 2, and 3.
A preliminary experiment was carried out to detect which element of $\xi$ is effective for the obstacle avoidance. When a value was given to the 1st or 3rd element, the attitude of the manipulator greatly changed. The 1st and 3rd elements, $\xi_1$ and $\xi_3$, are therefore given values and the other elements are set to zero for the simplification of the problem. The values of $\xi_1$ and $\xi_3$ are calculated from

$$
\xi_{1,3} = \begin{cases} 
  k_a \left( \frac{L_{\text{max}} - d_{\text{min}}}{L_{\text{max}} - L_{\text{min}}} \right) : d_{\text{min}} \leq L_{\text{max}}, \\
  0 : d_{\text{min}} > L_{\text{max}},
\end{cases}
$$

where $k_a$ is a positive constant, $L_{\text{min}}$ is the radius of the inelastic sphere, $L_{\text{max}}$ is the radius of the elastic sphere, and $d_{\text{min}}$ is the distance between the nearest obstacle and the manipulator. In this paper, $L_{\text{min}} = 0.15 \text{ m}$, $L_{\text{max}} = 0.25 \text{ m}$, and $k_a = 0.3 \text{ rad/s}$. The value of $\xi_1$ or $\xi_3$ is shown in Figure 5. As the obstacle approaches the manipulator, the value of $\xi_1$ or $\xi_3$ increases and then the attitude of the manipulator changes to avoid the obstacle.
3.3. Priority of Avoidance. Since the avoidance motions may conflict with the follow motions, the priority of avoidance is introduced. The priority of avoidance means the weight between the follow motions generated by (6) and the avoidance motions caused by (7) and (8). The value of the priority of avoidance is greater when an obstacle is close to the manipulator. The priority of avoidance \( \alpha \) is defined as

\[
\alpha = \begin{cases} 
\exp \left( -k_h \frac{d_{\text{min}} - L_{\text{min}}}{L_{\text{max}} - L_{\text{min}}} \right) & : d_{\text{min}} \geq L_{\text{min}}, \\
1 & : d_{\text{min}} < L_{\text{min}},
\end{cases}
\]

(9)

where \( k_h \) is a positive constant, \( k_h = 5.0 \) in this paper. The value of the priority \( \alpha \) is shown in Figure 6. According to the priority of avoidance \( \alpha \), \( F_{\text{ext}} \) in (4) is calculated as

\[
F_{\text{ext}} = (1 - \alpha) F_{\text{act}},
\]

(10)

where \( F_{\text{act}} \) is the actual applied force measured with the force sensor. \( F_{\text{ext}} = 0 \) at \( \alpha = 1 \) \( (d_{\text{min}} < L_{\text{min}}) \) means that only the avoidance motions are carried out without the follow motions, and \( F_{\text{ext}} = F_{\text{act}} \) at \( \alpha = 0 \) \( (d_{\text{min}} \geq L_{\text{max}}) \) means that only the follow motions are carried out without the avoidance motions. When the manipulator is close to the obstacle, the avoidance motions should precede the follow motions for the safety. Otherwise, the manipulator should follow the user’s motion as much as possible. Therefore, an exponential function is used in (9), so that the value of \( \alpha \) rapidly increases as the value of \( d_{\text{min}} \) approaches \( L_{\text{min}} \).

4. Simulation Model of Manipulator

A simulation model of the manipulator is constructed. The link parameters of the manipulator are shown in Figure 7, and the values of the link parameters and the moment of inertia of the links are shown in Tables 1 and 2, respectively. These values are calculated by measuring the manipulator.

The manipulator with the initial joint angle vector \( \theta(0) = [0, \pi/6, 0, \pi/3, 0, 0, 0]^{\text{T}} \) rad operates by giving some adequate reference path of the end-effector. The results are shown in Figures 8 and 9. These figures show the time history of the position of the end-effector, and the fine line and the bold one denote the simulation result and the experimental one, respectively. The simulation results coincide with the experimental ones. Though the details are omitted, the similar results are also obtained in other experimental situations. Therefore, this model is used in simulation.

5. Simulation Results of Obstacle Avoidance

The usefulness of the proposed method is demonstrated in simulation. Figure 10 shows the initial state of the obstacle avoidance simulation. The pink sphere denotes the inner virtual sphere with the radius \( L_{\text{min}} \). The initial joint angle vector \( \theta(0) = [0, \pi/4, 0, \pi/2, 0 - \pi/4, 0]^{\text{T}} \) rad and the actual applied force \( F_{\text{act}} \) is shown in Figure 11. The obstacle is a sphere of 0.05 m radius and its center is located at \([0.4, 0.3, 0.78]^{\text{T}}\) m.

5.1. Obstacle Avoidance Using Kinematic Redundancy. The distance between the obstacle and the manipulator \( d_{\text{min}} \) is shown in Figure 12, where only \( \xi_1 \) is calculated by (8) in Case 1 and both \( \xi_1 \) and \( \xi_3 \) are done in Case 2. The priority of avoidance \( \alpha \) is not used in both cases, that is, \( F_{\text{ext}} = F_{\text{act}} \). The minimum value of \( d_{\text{min}} \) in Case 2 is greater than that in Case 1. This means that Case 2 using both \( \xi_1 \) and \( \xi_3 \) is better than Case 1 using only \( \xi_1 \) from the viewpoint of obstacle avoidance. The manipulators in Cases 1 and 2 collide with the obstacle, since the distance \( d_{\text{min}} \) is less than \( L_{\text{min}} \). The scenes in Cases 1 and 2 are shown in Figures 13 and 14, respectively. The collision that the obstacle enters the inner sphere is confirmed from the last scene in Figures 13 and 14.

5.2. Obstacle Avoidance Using Kinematic Redundancy and Priority of Avoidance. The priority of obstacle \( \alpha \) is used in Case 3, where both \( \xi_1 \) and \( \xi_3 \) are calculated by (8), since the result in Case 2 is better than that in Case 1. The distance \( d_{\text{min}} \) in Case 3 is also shown in Figure 12. The value of \( d_{\text{min}} \) is never less than \( L_{\text{min}} \). This means that there is no collision between the obstacle and the manipulator. The scenes in Case 3 are
shown in Figure 15. No collision between the inner sphere and the obstacle is confirmed in Figure 15.

### 6. Experimental Results of Obstacle Avoidance

The validity of the proposed method is verified in the experiment. Figure 16 shows the initial state of obstacle avoidance experiment. The initial joint angle vector $\mathbf{\theta}(0)$ is the same as that in simulation. The obstacle is a square pole with $0.1 \times 0.1 \times 0.35$ m and its center is located at the same point in simulation. An experimenter who is a healthy person applies the force to the end-effector in $y$-axis direction.

The applied force measured with the force sensor is plotted in Figure 17. The experimenter applies the vibrational force to the positive direction of $y$-axis, the right direction in Figure 16. The vibration may be reduced by adjusting the impedance parameters $M_1$, $B_1$, and $K_1$ in (3). The position of the 4th joint of the manipulator on $y$-axis and the distance $d_{\text{min}}$ are plotted in Figures 18 and 19, respectively. The 4th joint moves to the positive direction of $y$-axis according to the applied force until about 4 s which causes the value of $d_{\text{min}}$ to be small. When the value of $d_{\text{min}}$ is small or the 4th joint is close to the obstacle, the avoidance motion predominates. The 4th joint moves to the negative direction of $y$-axis from about 4 to 6 s in Figure 18. This motion causes the increase of the value of $d_{\text{min}}$ in Figure 19. There is no collision between the manipulator and the obstacle, since $d_{\text{min}} > L_{\text{min}}$ during the experiment in Figure 19. The scenes of the experiment are shown in Figure 20. The follow motion and the avoidance motion are demonstrated.

### 7. Conclusions

In this paper, an obstacle avoidance method of action support 7-DOF manipulators has been realized by using impedance control and kinematic redundancy of the manipulator. A joint rate vector has been used to avoid obstacles in the way of changing the posture of the manipulators. The joint rate vector has been calculated from the distance between obstacles and the manipulator. The concept of the priority of avoidance has been introduced, so that avoidance motions precede follow motions when obstacles are close to the manipulator. The usefulness of the proposed method has been demonstrated through obstacle avoidance simulations and experiments.
