**ESCULENTOSIDE A (EsA)** is a saponin isolated from the roots of *Phytolacca esculenta*. Previous experiments have shown that it has strong anti-inflammatory effects. To investigate the mechanism of anti-inflammatory effects of *esculentoside A* (EsA), [3H] arachidonic acid (AA) prelabelled murine macrophage and radioimmunoassay were used to test the effect of EsA on the total release of AA and prostaglandin E₂ in culture supernatants. The results showed that EsA had no significant effect on the total release of AA from murine macrophages. EsA (2.5–10 μmol/l), from unstimulated murine peritoneal macrophages and rabbit synovial cells, could decrease the production of prostaglandin E₂. In A₂₃₁₈₇ and LPS-treated macrophages and synovial cells, EsA (10 μmol/l) could significantly decrease the prostaglandin E₂ production. These results confirmed that EsA exerted an inhibitory effect on prostaglandin E₂ production from murine macrophages and rabbit synovial cells.

**Introduction**

*Esculentoside A* (EsA) is a saponin isolated from the root of *Phytolacca esculenta*, and was identified as 3β-[β-D-glucopyranosyl-(1-4)-β-D-xylopyranosyl] phytolaccagenin. The structure of this compound is shown in Fig. 1. Previous experiments have shown that it has strong anti-inflammatory effects,³ significantly decreasing the production of tumour necrosis factor (TNF) from LPS stimulated murine macrophages⁴ and platelet activating factor (PAF) from A₂₃₁₈₇ stimulated rat macrophages.³ EsA also inhibited IL-1 production and phagocytic activity in murine macrophages.⁴ Prostaglandin E₂ was an important inflammatory mediator and was found at the site of inflammation. PGE₂ caused vasodilation leading to redness.⁵ It has been implicated in the angiogenesis required for the spread of the pannus in the synovial hyperplasia component of rheumatoid arthritis.⁶ PGE₂ is an arachidonic acid (AA) metabolite. In order to study the mechanism of the anti-inflammatory effect of EsA, this paper studied the effect of EsA on AA release from macrophages and the production of prostaglandin E₂ from murine peritoneal macrophages and rabbit synovial cells.

**Materials and Methods**

Reagents

RPMI-1640, MEM lipopolysaccharides (*Escherichia coli* 055:B5), calcimycin (ionophores, A₂₃₁₈₇), zymosan, trypsin were purchased from Sigma (USA), [5,6,8,9,11,12,14,15³H]arachidonic acid (8029 GBq/mmol) was purchased from Amersham. PGE₂ radio-immunoassay (RIA) kit was obtained from the Chinese Academy of
Medical Sciences. EsA was kindly provided by Dr Y. H. Yi (Department of Phytochemistry, College of Pharmacy, Second Military Medical University). Thioglycolate was supplied by the Shanghai Biological Research Institute.

Preparation of murine macrophages

Thioglycolate medium (1 ml, 3%) was injected i.p. into the C57 BL/6 mice. Four days later the cells in the peritoneal cavity were harvested with D-Hank’s solution, washed twice in RPMI-640 and adhered for 2 h at 37°C in a CO2 incubator. The nonadherent cells were decanted and the remaining adherent cells were digested with trypsin (0.25%) for about 3–4 min. RPMI-1640 containing 10% FCS was added to the culture bottle and the cell suspension was adjusted to 10⁶ ml with RPMI-1640 containing 10% FCS and disposed at 1 ml/well in 24-well plates.

Rabbit synovial cells culture

Synovial cells were prepared from a rabbit (weighing 2500–3000 g). Briefly, the rabbit was killed by bleeding. Synovium was taken out under ascetic conditions and cut in 1–2 mm³. The synovium was directly adhered on to the bottle, MEM (including 20% FCS, 200 μg/ml glutamin) was added to the bottle. The medium was refreshed after 2–3 days. The synovium was taken out when the synovial cells confluenced.

[^]{\text{[3]H}}\text{arachidonic acid uptake by murine macrophages}

The experiment was carried out as previously reported.² Briefly, 10⁷ macrophages in 1 ml medium (containing 10% FCS) were added to 35 mm culture dishes for 2 h. Nonadherent cells were washed away by D-Hank’s solution. [^]{\text{[3]H}}\text{AA, 18500 Bq in 1 ml RPMI-1640 were added to each well for 4 h. The supernatant was decanted and the cells were washed twice. Zymosan, 400 μg/ml was added to each well after EsA in 1 ml RPMI-1640 at different concentrations was co-cultured with macrophages for 20 min. The supernatants were collected at 2, 5 and 15 h and radioactivity was counted in a β-scintillator.}

Measurement of prostaglandin E₂

The experiment was carried out as in Ref. 6. The rabbit’s synovial cells (2 × 10⁵/ml) and murine peritoneal macrophages (1 × 10⁶/ml) in 1 ml medium (MEM containing 10% FCS) was seeded in wells respectively and incubated for 24 h. The supernatants were decanted and the cells were washed with MEM three times. A₂₃₁₈₇ and LPS were added in the presence and absence of EsA. After 24 h incubation the supernatants were adjusted to pH 3.5 with 10% HCOOH and extracted with ethylacetate twice (2 ml each time). The organic section was evaporated and the residual was reconstituted with 200 μl RIA assay buffer. The PGE₂ content was tested and expressed as ng/2 × 10⁵ synovial cells and ng/10⁶ macrophages respectively.

Statistics

Each experiment was carried out three times and the results presented here were representative of the three experiments. The same tendencies occurred in the parallel experiments. The results were expressed as the arithmetic mean ± SEM. The differences between the control group and treatment groups were analysed by Student’s t-test; P < 0.05 was regarded as significant.

Results

Total release of AA from murine macrophages

EsA (2.5–10 μmol/l) had no significant effect on total release of AA from zymosan (400 μg/ml) treated murine macrophages (Fig. 2).

PGE₂ production from murine peritoneal macrophages

EsA (2.5–10 μmol/l) inhibited PGE₂ production from unstimulated murine peritoneal macrophages. In A₂₃₁₈₇ stimulated murine peritoneal
macrophages, EsA (5–10 \(\mu\)mol/l) could significantly suppress the PGE\(_2\) production; in LPS-treated groups EsA (10 \(\mu\)mol/l) could significantly inhibit PGE\(_2\) production (Fig. 3).

**PGE\(_2\) production from rabbit synovial cells**

The same results as for murine peritoneal macrophages were observed in rabbit synovial cells. EsA (2.5–10 \(\mu\)mol/l) inhibited PGE\(_2\) production from unstimulated rabbit synovial cells. In \(\text{A}_23187\) and LPS-treated rabbit synovial cells, EsA (10 \(\mu\)mol/l) could significantly suppress the PGE\(_2\) production (Fig. 4).

**Discussion**

The present study demonstrated that EsA suppressed the production of PGE\(_2\) from murine peritoneal macrophages and rabbit synovial cells. EsA at lower concentrations could inhibit PGE\(_2\) production from unstimulated macrophages and synovial cells. In \(\text{A}_23187\) and LPS-treated macrophages, the inhibitory concentration reached 10 \(\mu\)mol/l. That is to say, the inhibitory concentration of EsA on PGE\(_2\) production in stimulated cells is higher than that in unstimulated cells. Prostaglandins are products of oxidation of arachidonic acid. The cyclooxygenase (COX) enzyme is the first dedicated enzyme in prostaglandin synthesis. At present, there appear to be at least two COX isozymes: a constitutive enzyme denoted COX-I which is responsible for the physiological synthesis of prostaglandins in tissue, and an inducible form termed COX-II which appears to be the major enzyme responsible for inflammatory prostaglandin synthesis. Our studies in the present paper have shown that EsA could inhibit both physiological and inflammatory prostaglandins’ production from macrophages and synovial cells. PGE\(_2\) is a metabolite of AA. We assumed that EsA inhibited PGE\(_2\) production through its inhibitory effect on the release of AA. The results in Fig. 2 confirmed that EsA had no significant effect on the release of AA. Previous experiments proved that released AA could be re-uptake by cell membrane. In the present research paper, our experiments confirmed that EsA had no effect on AA release in \(^{3}\text{H}\)AA prelabelled murine macrophages. We did not know whether EsA could affect AA uptake by cell membrane or not. Further experiments about the effect of EsA on AA uptake by cell membrane, activity of cyclooxygenase, lipooxygenase or other pathways are needed to clarify the anti-inflammatory mechanism of EsA.
