ACUPUNCTURE has a beneficial effect when treating many diseases and painful conditions, and therefore is thought to be useful as a complementary therapy or to replace generally accepted pharmacological intervention. The attributive effect of acupuncture has been investigated in inflammatory diseases, including asthma, rhinitis, inflammatory bowel disease, rheumatoid arthritis, epicondylitis, complex regional pain syndrome type 1 and vasculitis. Large randomised trials demonstrating the immediate and sustained effect of acupuncture are missing. Mechanisms underlying the ascribed immunosuppressive actions of acupuncture are reviewed in this communication. The acupuncture-controlled release of neuropeptides from nerve endings and subsequent vasodilative and anti-inflammatory effects through calcitonine gene-related peptide is hypothesised. The complex interactions with substance P, the analgesic contribution of \( \beta \)-endorphin and the balance between cell-specific pro-inflammatory and anti-inflammatory cytokines tumour necrosis factor-\( \alpha \) and interleukin-10 are discussed.

Key words: Acupuncture, Inflammation, Neuropeptides, Cytokines, Nitric oxide

Introduction

In China, acupuncture has been used in the treatment of several diseases for at least 5200 years. In Europe and the USA, this integral part of traditional Chinese medicine has become a visible component of the health delivery system and has steadily claimed its usefulness in complementary medicine. Although sometimes without a clear objective beneficial effect, an increasing number of patients, especially those suffering from chronic diseases, are seeking acupuncture treatment and pursue (lay claims to) additional healthcare. Consequently, this increases costs, even though it does not always provide a clear objective beneficial effect.\(^1\) The widespread application of acupuncture includes the treatment of infections, inflammatory diseases like rheumatoid arthritis, autonomic dysfunction, neurological diseases like migraine, pain, cardiovascular diseases, pulmonary diseases like asthma, drug abuse, psychological disorders and many other illnesses.\(^2\) Based on the effects seen in this variety of diseases, acupuncture could be divided into two main subjects: acupuncture analgesia and curative acupuncture. In general, analgesia is obtained by short-term acupuncture, whereas curative acupuncture requires long-term acupuncture treatment procedures. Traditional Chinese acupuncture is characterised by a holistic approach to the management of the disease. The skill of the acupuncturist lies in the ability to work not only with a clear-cut diagnosis, but also takes into account the complex pattern of disease-related factors. The exact pattern and degree of disharmony is unique for each individual. Therefore, the practitioner of traditional acupuncture will approach each patient with a personalised treatment plan. This plan focuses on improving the overall well-being of the patient, rather than the isolated treatment of specific symptoms or disease.

The basic health concept in traditional Chinese medicine consists of the body's vital energy (Qi), circulating unidirectionally through a complex network of channels (meridians) just beneath the skin, but also moving within blood vessels. It permeates organs and tissues, and is behind all physiological processes. Health is the harmonious, uninterrupted flow of Qi, and disease ensues when there is disruption of Qi flow. Factors that can affect Qi flow include emotional states such as anxiety, stress, anger, fear or grief, poor nutrition, weather conditions, hereditary factors, infections and trauma. By inserting needles, the acupuncturist tries to recover the equilibrium (the equal and dynamic opposite qualities of Yin and Yang) between physical, emotional and spiritual aspects of the individual, and to improve energy flow and energy quality. Additional activation can be obtained through manipulation of the needle or electro-stimulation at different frequencies. The most common manifestations of Yin and...
Yang in diseases are excess and deficiency states. Health is defined as the balance of Yin and Yang. In the case of inflammation, differential effects of acupuncture on acute and chronic stages of the disease could be considered, more or less expressed by clinical symptoms like burning pain, redness, swelling, changing temperature and loss of function. Beyond these manifestations, inflammatory mediators could represent subsequent mechanisms that are involved, but could also represent disease activity. For example, in inflammatory bowel disease, the blood flow is increased and vascular resistance diminished, whereas the release of different inflammatory mediators is time and region dependent and could be influenced by external factors. In acupuncture, the insertion of a needle induces marked changes close to the needle in all the different tissues that are penetrated. These peripheral events might improve tissue function through vasodilatation in the skin due to axon reflexes, which cause an immediate flare reaction. This vasodilative effect could be caused by the release of calcitonin gene-related peptide (CGRP) upon stimulation of Aδ or C fibres. The local release of β-endorphin could be responsible for the short-term analgesic effect, whereas the neuropeptide-induced release of anti-inflammatory cytokines could be derived from lymphocytes and secondary activating cells, such as macrophages. In the periphery, the real level of CGRP is of crucial importance. Usually CGRP has been shown to be pro-inflammatory, but in low doses it has a potent anti-inflammatory action. In this respect the release of another neuropeptide, substance P, is not likely to attribute to this phenomenon, but could regulate CGRP release from nerve endings.

In the present review, a hypothesis is presented concerning the anti-inflammatory action of needle acupuncture through a ‘dose’-related and time-related release of CGRP and a hypothesised preferential shift to the subsequent formation of anti-inflammatory cytokines.

**Inflammatory diseases**

In the following, a number of inflammatory diseases will be reviewed in which acupuncture treatment was initiated as a complementary therapy or replacement for conventional pharmacological intervention. Then, the role of mediators of inflammation in acupuncture will be discussed and a proposed mechanism of action to use acupuncture will be hypothesised.

**Asthma**

Numerous uncontrolled trials as well as a limited number of controlled trials have been published with contradictory and conflicting results after the short-term or long-term use of acupuncture in the treatment of asthma. In most studies, a relatively small number of patients were included, whereas methodological procedures were incompletely described. Various outcome parameters such as lung function, quality-of-life questionnaires and reduction of medication were used to reflect improvement of the disease.

The use of acupuncture to suppress the daily intake of orally given corticosteroids and inhaled β2-adrenergic agonists was investigated. In an open trial, patients with bronchial asthma were treated by acupuncture. This resulted in a good therapeutic effect (96% effective rate). Patients initially were treated in 15 consecutive sessions and received 10 follow-up treatments to consolidate the curative effect as marked by a decrease of corticosteroid intake and diminished use of aerosols. The investigator concluded that at least 30 sessions in 3 months should be offered to initiate this effect, followed by 10 more sessions per year to prevent a relapse. The extensive treatment with acupuncture could explain the lack of effect seen in other studies.

In a double-blind cross-over study, the effect of 2 weeks of acupuncture treatment on patients with stable asthma was investigated. Although a significant improvement of the quality of life and a reduction of the usage of inhaled β2-adrenergic agonists was observed, the respiratory function was not affected. This is in contrast with another placebo-controlled study in which patients with moderate persistent asthma, who were only treated with inhaled β2-adrenergic agonists, received a treatment with acupuncture four times. This relatively short course of treatment did not affect daily intake of inhaled β2-adrenergic agonists. No changes in lung functions, bronchial hyper-reactivity or symptom scores were observed.

In a randomised, controlled study, both the additive effect of acupuncture to conventional therapy and the immune-modulating effects on patients with allergic asthma was monitored. All patients were treated 12 times for 30 min over a period of 4 weeks. Subjective parameters like the patients’ general well-being, and more objective parameters like biochemical measurements in blood, were determined before and after completion of the acupuncture treatment. General well-being significantly improved in the acupuncture group (79%) in comparison with the control group (47%). Furthermore, lymphocyte proliferation and CD3+ and CD4+ cells increased, whereas the number of eosinophils significantly decreased in the acupuncture group.
Single application of laser acupuncture performed in a double-blind, placebo-controlled, crossover study to investigate the protective effect on cold dry air hyperventilation-induced bronchoconstriction revealed no significant protection in paediatric and adolescent patients.\(^2\) Forced expiratory volume and the expiratory flow were unaffected by single laser acupuncture.

In 1991, Kleijnen et al. published a systematic review of 13 controlled clinical trials pertaining to the use of acupuncture in the treatment of asthma during the period 1963–1989.\(^20\) Only three studies of acceptable quality resulted in favourable effects. Recently, other systemic reviews and meta-analyses of all randomised clinical trials in the published literature comparing acupuncture at real and placebo points in asthmatic patients were performed. The period 1970–2000 was evaluated by Martin et al.\(^21\) Peak expiratory flow rate, forced expiratory volume and forced vital capacity were collected as objective outcome parameters. In this analysis, no significant overall effect of acupuncture to reduce asthma could be confirmed. After induction of bronchoconstriction, however, a significant effect was observed. The authors concluded that this meta-analysis was limited due to shortcomings of the individual trials and a not clearly described use of sham acupuncture. Others who reviewed the efficacy of acupuncture in asthma concluded that up to now evidence is lacking, also due to inadequately performed investigations.\(^22,23\) In conclusion, mainly based on clinical outcome parameters, there is presently not enough evidence to make specific recommendations about the value of acupuncture in the treatment of asthma (Table 1).

### Rhinitis

Treatment by acupuncture is frequent among adults with asthma and rhinosinusitis, and therefore should be taken into account by health-care providers.\(^1,24\) In acute sinusitis, acupuncture resulted in an improvement in children with chronic and recurring frontal sinusitis.\(^25\) In the treatment of seasonal allergic rhinitis, acupuncture has been proven to be effective. In a small single-blind crossover study, acupuncture (three times a week during a 4-week period) improved subjective symptom scores, although a reduction in medication was not observed.\(^26\) In allergen-provoked rhinitis, acupuncture, acupuncture therapy was not effective when regarding the objective criteria, although again symptom scores as registered in the diary of complaints revealed a reduction.\(^27\) Desensitisation of allergic rhinitis using acupuncture endermic points of the head with the extract of positive allergens proved to be effective in an open study including 102 cases. After a follow-up of 2 years, a significant population (72%) showed a curative effect, mainly reflected by a reduced diameter of redness and reduced swelling of the skin.\(^28\)

In an open study, the positive effect of acupuncture on atrophic rhinitis was demonstrated. The improvement was documented by functional changes of the nasal mucosa (mucociliary transport, secreted volume and surface temperature).\(^29\)

#### Inflammatory bowel disease

The use of alternative medicine in bowel diseases was already investigated almost two decades ago. Significantly more patients with irritable bowel syndrome (11%) appeared to consult practitioners of alternative medicine than patients with Crohn’s disease (4%).\(^30\) Nowadays, traditional and complementary therapies such as acupuncture are more frequently combined in the treatment, relief and control of Crohn’s disease.\(^31\) Until now, only limited data is available for the complementary use of acupuncture in ulcerative colitis with or without moxibustion.\(^32,34\) These data, however, indicate that acupuncture could attribute to recovery in patients with active inflammatory bowel disease.

#### Rheumatoid arthritis

In another autoimmune disease, rheumatoid arthritis, which sometimes also results in the development of Crohn’s disease, successful treatment with acupuncture\(^35\) and moxibustion has been reported.\(^36,37\) Although the results clearly showed a beneficial effect in the reduction of symptomatic pain, the small sample size is a matter of concern.

In other placebo-controlled cross-over studies, in a large number of patients with rheumatoid arthritis, acupuncture could not attribute to any improvement in general health, pain request or the examination of the number of swollen joints, nor to a diminished analgesic intake.\(^38,39\)

Until now, the usefulness of acupuncture as a complementary and alternative medical therapy in rheumatoid arthritis still has to be demonstrated in large randomised trials.\(^40\)

Epicondylitis

The clinical efficacy of acupuncture was also investigated in chronic lateral epicondylitis of the elbow (tennis elbow). The immediate analgesic effect of a single acupuncture stimulation in a placebo-controlled single-blind trial has been reported. In a comparative study, both classical and superficial needle insertion was studied in a short-term treatment schedule stimulating five selected acupuncture points during 10 treatments in 3 weeks. Classical acupuncture was only superior to superficial needle insertion after all treatments were applied, but not at 3-month and 1-year follow-ups. Laser treatment applied to the same acupuncture points, however, did not improve subjective and objective outcome parameters significantly in comparison with a placebo. Psychosomatic factors could attribute significantly in the positive short-term effects of pain reduction. As seen in the improvement of outcome parameters including pain scores, function, disability, strength and quality of life, short-term effects are promising but acupuncture failed to stabilise the disease and did not contribute to further recovery.

Complex regional pain syndrome type 1

Recently, we confirmed that complex regional pain syndrome type 1 (CRPS1), formerly indicated as post-traumatic sympathetic dystrophy or Sudeck’s atrophy, developed in one or more extremities, and should also be considered as the result of an inflammatory reaction after neurogenic stimulation. Two case reports and two randomised trials predominantly focused on pain reduction and have published improvements after long-term acupuncture treatment. Other symptoms of inflammatory reactions including swelling, mobility, temperature and redness were also observed. In comparison with sham-treated patients, no significant improvement of these parameters could be proven.

Vascular diseases

Inflammation of the vascular system could attribute to some of the afore-described inflammatory diseases. The promotion of blood circulation by acupuncture could positively affect the enrolment of the whole cascade of inflammatory mediators that are undoubt- edly involved in the subsequent processes during chronic inflammation. In the context of migraine, neurogenic inflammation could also play an important role. Elevated plasma levels of CGRP during headache suggest that this initial inflammatory mediator is involved. In general, acupuncture has additional value in the treatment of primary headaches.

**Table 2. Inflammatory mediators reported in acupuncture**

In general, inflammation is associated with increasing temperature, oedema, redness, pain and loss of function. Furthermore, the direct and indirect effects of individual neuropeptides, cytokines and vasoactive mediators could be considered to play an intermediate role during and after acupuncture has been assessed. Assuming local blood flow is indeed stimulated by acupuncture, the neurogenic formation of vasoactive mediators could regulate blood flow and blood distribution to affected organs and tissue after inflammation has been initiated. Acupuncture activates the defence systems. It influences specific and non-specific cellular influx, activation of cell proliferation and regulation of subsequently involved cells that will result in a complex mechanism of transport, further breakdown and clearance of all bioactive mediators (Table 2).

Neuropeptides

Calcitonine gene-related peptide is a potent vasodilator that has been shown to have a physiological and pathological role in neurogenic inflammation, migraine, thermal injury, circulatory shock, pregnancy and menopause, hypertension and heart failure, and has been proven to be cardioprotective. Both substance P and CGRP have important roles in oedema formation and inflammation, and when transported centrally these neuropeptides can cause excitation.

In patients with CRPS1, blood samples did not show an elevation of substance P and neuropeptide A, whereas neuropeptide Y, CGRP, bradykinin and vasoactive intestinal peptide (VIP) were increased four-fold. Intraneural substance P contributes to the severity of inflammation. After intra-arterial infusion in the human forearm, substance P provoked vasodilation, flushing and plasma extravasation. In musculocutaneous flaps in the rat, increased blood flow affected by acupuncture was comparable with the effects observed after injection of substance P and...
CGRP. In rats, acupuncture induced the release of substance P from peripheral terminals of primary sensory neurons. After repeated electro-acupuncture, significantly higher concentrations of substance P and other neuropeptides such as neurokinin A and neuropeptide Y were found in the rat brain. The acute release of neuropeptides can be mimicked and easily provoked after application of capsaicin, the bioactive substance of red pepper. Acupuncture could diminish capsaicin-induced oedema in the rat paw, indicating a prominent role for substance P and other neuropeptides.

In dogs, the concentrations of substance P were determined in the skin, muscle and subcutis of acupoints and control points, showing an increased release of substance P after acupuncture. On the other hand, an observation in rabbit tooth pulp showed that, after an initial substance P release had already been evoked, electroacupuncture suppressed this release.

In humans, during labour, the content of substance P in serum declined after acupuncture had been applied, but increased in patients suffering from fibromyalgia. In both observations the analgesic effect of acupuncture was significant. In samples taken from the saliva of healthy subjects, the release of substance P was hardly affected after acupuncture, although neuropeptide Y and CGRP were markedly increased.

Needling of acupuncture points could result in activation of afferent fibres of peripheral nerves, which induces the release of endogenous opiate peptides from nerve cells. Beta-endorphins are believed to play an important intermediate role in the regulation of the analgesic effects obtained through acupuncture. Beta-endorphin concentrations in spinal fluid and plasma of horses, however, were not elevated after acupuncture. Although prenatal acupuncture treatment in women significantly reduced the duration of labour, serum levels of beta-endorphin were not influenced. In another study, however, 90 patients suffering from various painful disorders were subjected to acupuncture. Plasma beta-endorphin levels were increased considerably, resulting in an elevated immunologic response reflected by lymphocyte markers CD3, CD4 and CD8.

In curative (long-term) acupuncture, interactions between beta-endorphins and cytokines could therefore result in an increased formation of anti-inflammatory cytokines such as interleukin (IL)-10 and/or a diminished production of pro-inflammatory cytokines, possibly being the most prominent mechanism of action underlying the attributive effect of acupuncture in chronic inflammatory diseases. Very recently, the existence of regulatory IL-10-dependent T-cell populations was documented in allergic diseases.

### Cytokines

Recently, the effect of acupuncture on regulation of cytokine production in asthma has been published. Clinical signs of asthma improved markedly. In peripheral blood of asthmatic patients, the mean IL-2 and IL-6 plasma levels were decreased, whereas interferon (IFN)-gamma, IL-4 and tumour necrosis factor (TNF)-alpha were increased. After acupuncture IFN-gamma, IL-2, IL-4 and IL-6 were elevated and TNF-alpha was reduced. In allergic rhinitis, plasma concentrations of IL-2, IL-6 and IL-10 were determined before and after acupuncture in comparison with healthy controls. In all allergic rhinitis patients, IL-10 levels were increased prior to real acupuncture, sham acupuncture or non-treatment. In the acupuncture group IL-10 was reduced, whereas IL-2 was hardly affected and IL-6 remained unchanged after therapy. In rheumatoid arthritis, IL-2 levels were lower than in the healthy controls. After acupuncture, this reduced IL-2 production was elevated. In a rat model for ulcerative colitis, acupuncture and moxibustion inhibited the expression of pro-inflammatory cytokines IL-1beta and IL-6.

In conclusion, the (im)balance between T helper 1 cell-derived and T helper 2 cell-derived pro-inflammatory and anti-inflammatory cytokines was reset by acupuncture.

### Nitric oxide

As some observations highlight the stimulating effects of acupuncture on muscle afferents and blood flow through autonomic reflexes, the attributive effect of nitric oxide (NO) through local release and/or induction after electrostimulation should also be considered. Significant and persistent increases in the arteriolar diameter were observed after electro-acupuncture. This effect was abolished in the presence of nitro-L-arginine methyl ester (L-NAME), indirectly indicating that NO plays a key role in the primary mechanisms that are involved in microcirculation. From rat studies, it has been shown that NO levels were increased in rat striatum after cerebral artery occlusion, ischaemia and reperfusion. Electro-acupuncture antagonised the ischaemia-elicited release of NO. The anticonvulsant effect of electro-acupuncture might be related to the decrease of the nitric oxide synthases neuronal nitric oxide synthase and inducible nitric oxide synthase. From these preliminary results it is not clear whether central effects evoked by electro-acupuncture are more pronounced than those observed in the circulatory system, especially when inflammation occurs and the endothelial-derived nitric oxide synthase produces sustained amounts of NO. Furthermore, a disturbed microcirculation through shunting of arterioles is also evoked by serotonin, another reasonable explanation.
could be possible to stimulate an acupuncture procedure without penetrating the skin. In this set-up, placebo-treated patients experienced less pain sensation, also expressed by a diminished visual analogue scale pain. Another acceptable approach could be the inclusion of sham laser acupuncture, but it is preferred that sham acupuncture is used, when not actively involved meridians are needled or superficial pricking is applied. Based on functional magnetic resonance imaging of the whole brain, it has however been demonstrated that superficial pricking revealed more signal intensity than minimal applied acupuncture.

From a pharmacotherapeutical point of view (kinetics, dynamics and dose finding), it is difficult to make comparisons between different acupuncture techniques that are used in not well-described studies. First, from traditional Chinese medicine, acupuncture should be considered and applied as an individually based therapy. Many factors and variables will influence the outcome of the therapy, such as: which of the acupoints and how many acupoints are chosen per treatment session? what is the reproducibility of the matrix of chosen acupoints? what is the type, depth, direction and manipulation of the inserted needle? what is the needle retention time and the length of the session? what is the frequency and total number of treatments? what is the follow-up? and what are the maintenance treatments? (Table 3) Furthermore, for Western scientists, the main part of the literature describing Chinese and Japanese trials performed on acupuncture is only available as translated abstracts. Not only is there a marked difference between Chinese and Japanese acupuncture, but Western educated and qualified acupuncturists apply acupuncture differently in comparison with ancient acupuncturists. In some studies performed in Western countries, Chinese guests scientists collaborated in these studies, and they were the ones who performed the acupuncture treatments during their stay. As a consequence, some specific methodological information is missing, which makes it virtually impossible to continue or repeat treatment schedules for specific purposes (Fig. 1). Recently, standards for reporting the outcome of controlled acupuncture trials have been published. Because the intensity and frequency of acupuncture as a complementary therapy will be individually chosen, one should also consider the subtype of the disease. In asthma, for instance, some aspects such as allergic, acute, chronic, exercise or cold-induced asthma should be considered, which will certainly affect the outcome of the acupuncture therapy. In most studies, subjective parameters (e.g. visual analogue scale pain, life questionnaires) are used. In open and single-blinded trials, the results clearly depend on the sample size and the number of repeated measurements. Object-

why acupuncture could be (only) effective for the short-term treatment of migraine.

**Discussion**

**Pitfalls in methodology of measuring the use of acupuncture**

In general, acupuncture trials include a limited number of patients. These trials are heterogeneous regarding patients, interventions and outcome measures and (therefore) present contradictory results. Most obvious is the need for well-designed and larger clinical trials. Research in the area of complementary medicine such as acupuncture should be performed and evaluated at the same high-quality standards as research in the use of conventional therapies. In some studies, acupuncture points that were used in the sham groups could be effective according to traditional Chinese medicine. Therefore, with regard to the standardised choice of acupuncture points in the set-up of repeatedly applied acupuncture in sham acupuncture controlled clinical trials, the main problem to be solved is to determine the originally individualised treatment strategy that includes this approach.

A matter of debate is the set-up of randomised trials comparing placebo, sham or non-treatment. A placebo needle has been designed, with which it
CGRP, substance P and that, after antidromic stimulation of the nociceptor, the underlying mechanism of acupuncture could be preliminary results. Undoubtedly indicate whether acupuncture is advisable as a complementary therapy and confirm research on underlying mechanisms indicating the specific release or inhibitory action on the formation of inflammatory mediators such as substance P, CGRP, β-endorphin and cytokines would undoubtedly indicate whether acupuncture is advisable as a complementary therapy and confirm preliminary results.

**Mechanism of action of acupuncture: a concept**

The underlying mechanism of acupuncture could be that, after antidromic stimulation of the nociceptor, CGRP, substance P and β-endorphin are all released. Initially, substance P will activate mast cells and in a later phase also macrophages to secrete inflammatory mediators. As a consequence, the mast cell will not only secrete serotonin and histamine, but also cytokines such as TNF-α. In turn, TNF-α could prime sensory nerve endings. The activation of mast cells and mast cell-mediated inflammation is regulated by NO. Macrophages will produce a number of cytokines and eicosanoids. In the blood vessel, CGRP will directly or indirectly affect vasodilation and extravasation via the stimulation of NO, VIP and bradykinin. Delayed dilatation to bradykinin is cyclooxygenase-2 dependent, whereas prostaglandin E2 potentiates bradykinin and induces pain. Substance P regulates the vasodilator activity of CGRP through the action of proteases from mast cells. In calcium/alpha calcitonin gene-related peptide knockout mice, nociceptive hypersensibility was reduced. Furthermore, it has been shown that both CGRP and VIP counteract nicotine-induced sweating. The suppressing or potentiating effects of substance P and CGRP on metacholine-mediated cholinergic sweating, however, were dose dependent. The ability of sweating to regulate skin temperature is well known and is more pronounced in men than in women. In women with chronic pelvic pain, intravenous infusion with CGRP resulted in a significant increase of skin temperature and complaints in comparison with healthy volunteers, whereas VIP did not provoke pain nor affect temperature, suggesting the existence of a neurovascular disorder. There has been some evidence that hot flashes observed in menopausal women are due to up-regulation of CGRP receptors following ovarian hormone deficiency. In ovariectomised rats, the greatest vasodilation and skin temperature increase was observed after CGRP, with less effect of VIP and the smallest effect seen after substance P. In men who showed hot flashes after castration due to prostate carcinoma, plasma CGRP levels were elevated. These results suggest that the vasodilative and skin temperature increasing effect of CGRP could be due to a diminished amount of (female) sex steroids. This could explain the higher incidence of migraine in women and menstrual-related migraine, and the prevalence of some diseases in women, such as CRPS1 and carpal tunnel syndrome. In addition, studies on gender differences in pressure pain threshold in healthy humans showed a significant decrease in females in comparison with males.

In general, the acute, short-term and long-term effects of acupuncture are comparable with actions observed by the use of capsaicin. Capsaicin is the bioactive component of chili pepper. Application of capsaicin to the skin or mucus membranes initially results in irritation and hyperaesthesia. This momentary effect is attributed to the release of substance P from peripheral sensory C fibres. Repeated application of capsaicin would result in a depleted secretion of substance P from neurons. During inflammation these effects are more pronounced. It is conceivable that the simultaneous release of CGRP will follow the same cascade of secretion. The antinociceptive effects of a capsaicin analogue, civamide, when given orally to rats, have been described. Besides the receptor related effects of this vanilloid receptor agonist and neuronal calcium channel blocker, proposed actions could also include inhibition of the neuronal release of CGRP and substance P. That could explain the acute and prophylactic properties of this substance in the treatment of cluster headaches. In concordance with these findings, therapeutic (needle) acupuncture induces peripheral events that might improve tissue function and induce local pain relief, based on mechanisms that include axon reflexes, release of neuropeptides such as CGRP, anti-inflammatory actions of neuropeptides like substance P, and local release of β-endorphin. Furthermore, sympathetic
inhibition could occur and levels of stress hormones and sex steroids could be reduced. Intense and frequently applied acupuncture gives rise to more pain, which could be due to high amounts of secreted CGRP (comparable with initial effects of capsaicin) when the inflammatory effect is predominant. Pain relief sometimes is observed after some days of treatment, possibly due to the delayed release of β-endorphins and the accumulated dose needed to be effective through IL-10 formation. IL-10 formation is limited, as has been shown in IL-10-dependent T-cell populations.

As already stated in the Introduction, high levels of CGRP have been shown to be pro-inflammatory but, on the contrary, CGRP in low concentrations exerts potent anti-inflammatory actions. The main attributive effect of substance P could be the feedback regulation of CGRP release from nerve endings. The effects of neuropeptides may vary from one organ or tissue to another. The presence and time-dependent contribution of mast cells, macrophages and other inflammatory cells to produce mediators that activate or counteract the inflammatory process may be of crucial importance (Fig. 2). Therefore, a well-performed and frequently applied ‘low-dose’ treatment of acupuncture could provoke a sustained release of CGRP with anti-inflammatory activity, without stimulation of pro-inflammatory cells. That could be the explanation why acupuncture only seems to be beneficial in the treatment of some inflammatory conditions.

![Diagram](image_url)

**FIG. 2.** Schematic overview of proposed interplay between nerve cells and inflammatory cells, and site of action of acupuncture and capsaicin or antagonists: role of neuropeptides, cytokines, nitric oxide and eicosanoids. NOS, Nitric oxide synthase; SP, substance P; Th, T helper.
A number of observations on the anti-inflammatory actions of acupuncture have been published, repre-
senting open studies and randomised trials. Both short-term and long-term treatment schedules were
performed, with varying number of acupuncture points, acupuncture frequency and additional appli-
cation of electro-stimulation. The value of comple-
mentary acupuncture in the treatment of inflammatory diseases is still questioned. In asthma, the
highest effective rate observed was obtained after
