Background. Dexamethasone (Dex) has been used to reduce inflammation in preterm infants with assistive ventilation and to prevent chronic lung diseases. However, Dex treatment results in adverse effects on the brain. Since the hippocampus contains a high density of glucocorticoid receptors (GCRs), we hypothesized that Dex affects neurogenesis in the hippocampus through inflammatory mediators.

Methods. Albino Wistar rat pups first received a single dose of Dex (0.5 mg/kg) on postnatal day 1 (P1) and were sacrificed on P2, P3, P5, and P7. One group of Dex-treated pups (Dex-treated D1D2) was given mifepristone (RU486, a GCR antagonist) on P1 and sacrificed on P2. Hippocampi were isolated for western blot analysis, TUNEL, cleaved-caspase 3 staining for cell counts, and morphological assessment. Control pups received normal saline (NS).

Results. Dex reduced the developmental gain in body weight, but had no effect on brain weight. In the Dex-treated D1D2 group, apoptotic cells increased in number based on TUNEL and cleaved-caspase 3 staining. Most of the apoptotic cells expressed the neural progenitor cell marker nestin. Dex-induced apoptosis in P1 pups was markedly reduced (60%) by pretreatment with RU486, indicating the involvement of GCRs.

Conclusion. Early administration of Dex results in apoptosis of neural progenitor cells in the hippocampus and this is mediated through GCRs.

1. Introduction

Corticosteroids are used in preterm infants to suppress inflammation, to facilitate extubation, and/or to prevent chronic lung diseases [1–3]. However, such early dexamethasone (Dex) therapy can result in an adverse neurodevelopmental outcome [4, 5]. For example, Dex treatment reduces cerebral gray matter volume without affecting white matter and the basal ganglia, suggesting that Dex affects only certain cells in the brain [6–8].

Neurons in the dentate gyrus (DG) of the hippocampus continue to divide after term and therefore remain vulnerable to the adverse effects of steroids during the early postnatal period [9–11]. Cells in the hippocampus have a high density of glucocorticoid receptors (GCRs) [12] suggesting that they could be affected by Dex [8–13]. Dex is known to change synaptic plasticity in the hippocampus [14]. As rat and human develop over different embryonic time scales [15], rat pups on P1 correspond to the human fetus at about week 22 to 24 of gestation. The equivalence in development is reflected in brain weight, neurochemistry, electroencephalography, and synaptogenesis [16]. Therefore, rat pups can be used as an animal model for human preterm infants undergoing drug exposure [17].

Here, we studied the effects of single-dose Dex therapy and the role of GCRs on hippocampal development.

2. Materials and Methods

2.1. Animals. The study was approved by the Animal Care and Use Committee of National Cheng Kung University. Time-dated pregnant Albino Wistar rats (body weight 250–300 g) were used. Food and water were provided ad libitum. The dams were allowed to deliver naturally on
gestational day 21 ± 1. Animals were kept in a ventilated room at 22 ± 2 °C under a 12/12 h light/dark cycle. The day of birth was designated P0.

2.2. Study Design. In a preliminary study, each litter was divided into two groups: the Dex group received a dose of Dex phosphate (0.1, 0.2, or 0.5 mg/kg, i.p.) (Oradexon, 4 mg/mL, Organon, the Netherlands) and controls received an equal volume of normal saline (NS). Compared with the controls, changes in apoptosis were only observed with Dex 0.5 mg/kg, so this dose was used in the subsequent experiments. On day 1 (P1) pups received a single dose of 0.5 mg/kg Dex or NS. On P2, P3, P5, and P7, pups were anesthetized and euthanized with 10% chloral hydrate (W/V, 300 mg/kg, Riedel-de Haen, Germany) and then infused transcardially with NS. The body and isolated brain weights were measured to the nearest milligram. Brain tissues were processed histologically following standard protocols and cut serially at 5 μm in the coronal plane.

2.3. Immunohistochemical and Immunofluorescence Staining. Brain sections were matched to the E22 coronal plates 12 to 15 of the prenatal rat brain development atlas [18]. Sections were stained by immunohistochemical (IHC) and/or immunofluorescence (IF), TUNEL, and double-IF methods, using the protocols recommended by the manufacturers or described previously [19]. The following TUNEL detection kits and primary antibodies were used: TdT-Frag EL DNA fragmentation detection kit, ApopTag Red in situ apoptosis detection kit (Calbiochem, San Diego, CA), antibrain-derived neurotrophic factor (diluted 1:2000), and rabbit antiglucocorticoid (diluted 1:50) (Santa Cruz Biotechnology), anti-OX-6 (diluted 1:50; AbD Serotec, Oxford, UK), and anti-NeuN (diluted 1:200; Chemi-Con, CruzBiotechnology), anti-OX-6 (diluted 1:50; AbDSerotec, Oxford, UK), and anti-NeuN (diluted 1:200; Chemi-Con, CruzBiotechnology), anti-NeuN (diluted 1:200; Chemi-Con, CruzBiotechnology), anti-NeuN (diluted 1:200; Chemi-Con, CruzBiotechnology), anti-NeuN (diluted 1:200; Chemi-Con, CruzBiotechnology), anti-NeuN (diluted 1:200; Chemi-Con, CruzBiotechnology), and anti-NeuN (diluted 1:200; Chemi-Con, CruzBiotechnology). All sections were matched to the same anatomical sites for comparing cell counts between the Dex-treated and control groups. For IF staining, biotinylated anti-rabbit and asthesecondaryantibodies;forIHCstaininggoatanti-rabbit anti-mouse IgG (1:400; Victor, Burlingame, CA) were used as secondary antibodies; for IHC staining goat anti-rabbit IgG, H&L Chain specific Texas Red conjugate and rat anti-mouse IgG H&L Chain specific fluorescein conjugate (diluted 1:400; Calbiochem, San Diego, CA) were used as secondary antibodies. Sections were also double stained using the above primary antibodies and dilutions.

2.4. TUNEL Assay. The sections were subjected to TUNEL (Oncogene Research, Cambridge, MA) and IF staining. The signal was detected by the streptavidin-horseradish peroxidase conjugate and diaminobenzidine reaction.

2.5. Counts of Cells Stained for TUNEL, Cleaved-Caspase 3, and NeuN. Sections were examined by light microscopy and the images captured by a video camera coupled to a desktop computer (Eclipse 80i, Nikon, Japan). TUNEL-positive cells were identified and counted at 400x magnification. The numbers of TUNEL-positive cells in the DG, cornu ammonis 1 (CA1), CA2, and CA3 in the hippocampus were counted. For comparison with the control, sections at the same level were analyzed. Four sections were counted for each pup and the results were averaged. Cleaved-caspase 3- and NeuN-positive cells were counted at 400x magnification in four, 1 mm² areas in the DG. Data were validated by TissueGnostics FACS-like Tissue Cytometry software (Vienna, Austria). This method was also applied to IHC, IF, and double-stained cells in subsequent experiments.

2.6. Tissue Dissection and Western Blot Analysis. The hippocampi were dissected from the pups on P2, one day after Dex or NS treatment (D1D2). Western blots were performed on cytosolic and nuclear fractions of the hippocampus homogenates as described previously [19]. Briefly, 20 μg protein homogenate, determined by the Bradford protein assay (Bio-Rad, Hercules, CA), was separated by SDS-PAGE, blotted onto nitrocellulose (Hy-Bond, Amersham, Arlington Heights, IL) and blocked with nonfat dry milk. Blots were incubated with specific primary antibody, followed by incubation with horseradish-peroxidase-conjugated secondary antibodies (Abcam, Cambridge, UK) and detected by enhanced chemiluminescence (Bio-Rad). Samples were normalized to actin and proliferating cell nuclear antigen (pCNA) proteins (EMD Millipore). Each experiment was repeated at least three times.

2.7. Mifepristone (RU486) Treatment. The GCR antagonist, RU486 (Tocris Bioscience, Ellisville, MO), was dissolved in 100 mM DMSO. Thirty minutes prior to Dex injection, P1 pups received 25 mg/kg RU486 or vehicle intraperitoneally [20]. The RU486- and DMSO-treated pups (D1D2) with or without Dex treatment were euthanized on P2, and morphological and biochemical analyses were carried out as described above.

2.8. Statistical Analysis. Quantitative results are expressed as mean ± standard error (SE). Statistical analyses were performed using one- or two-way ANOVA with a multiple comparisons posttest or the Wilcoxon signed-rank test as appropriate. P values < 0.05 were considered statistically significant. The body and brain weight results were analyzed by mixed-model ANOVA with age as the within-subject factor and Dex as the between-subject factor.

3. Results

3.1. Body and Brain Weights. Pups that had received Dex (0.5 mg/kg) showed reduced body weights. In contrast, no difference in the developmental growth of brain weight was found between the Dex and control groups (Table 1).

3.2. Apoptotic Cell Death. More TUNEL-positive and cleaved-caspase 3-positive cells were found in the DG of P1 D1D2 Dex-treated group (Figures 1(b) and 1(e)), with

N: number of pups; *=days of normal saline (NS) or dexamethasone (Dex) administration to the rat pups.

In P1 group, after Dex or NS injection on day 1, the pups were sacrificed on days 2, 3, 5, and 7.
Compared pups injected with dexamethasone (Dex) and normal saline (NS) by using two-way ANOVA.

3.3. Cell Counts and Coexpression of Apoptosis and Neuronal Maturation Markers. Representative results of TUNEL, nestin, and NeuN staining are shown in Figure 2. We found about twice as many TUNEL-positive cells in the Dex-treated D1D2 group (38.1 ± 1.1) compared with the control (21.8 ± 1.2; P < 0.05) (Figure 3(a)). The Dex-treated group had a greater proportion of TUNEL-positive cells (0.75 ± 0.01) that coexpressed nestin than control (0.61 ± 0.01) (Figure 3(b)).

The proportion of TUNEL-positive cells coexpressing NeuN was also greater in the Dex-treated group (0.68 ± 0.10) than in control (0.64 ± 0.01; P < 0.05) (Figure 3(c))

3.4. Glucocorticoid Receptors (GCRs) and Mifepristone (RU486) in Dex-Induced Apoptosis. Western blot analysis showed that the nuclear fractions of GCRs in the hippocampus were upregulated in the Dex-treated D1D2 group (Figure 4). The Dex-retarded developmental gain in body weight was blocked by RU486 while neither Dex nor RU486 affected the brain weight in this group (Table 2).

Furthermore, Dex-induced apoptosis in the P1 D1D2 group was reduced by the preadministration of RU486 (Figure 5).

4. Discussion
Steroids have long been used in the treatment of respiratory problems in preterm infants [21]. The complications of adverse neurological effects (such as increased risk of cerebral palsy and neurodevelopment impairment [4, 22, 23] demand the reevaluation of steroid-based therapeutic strategies in postnatal practice [23–26]. The safe timing and dosage of Dex remain undecided for preterm patients [4].

Our results from the P1 rat pups, equivalent to 24-week preterm infants, showed that Dex retarded the developmental gain in body weight, consistent with earlier reports [27–29]. Furthermore, neonatal Dex exposure leads to delayed neurodevelopment and physical maturation, suggesting that Dex permanently alters neuronal functions during this period, particularly those associated with the hypothalamic-pituitary-adrenal axis [27–29]. Other studies showed that neonatal Dex exposure reduces brain weight [10, 28–32]. On the contrary, our data showed no such change. We attribute this discrepancy to the differences in timing, dosage regimes, and/or the preparation of Dex [28, 31, 32]. Among clinicians, the general consensus is that a lower dose of Dex (0.1–0.2 mg/kg/day) facilitates tracheal extubation and reduces the risk of chronic-lung disease. This study revealed no deleterious effects on the brain with single low doses of Dex (0.1–0.2 mg/kg), although it became harmful at a higher dose (0.5 mg/kg). The subgranular zone of the DG contains a reserve of neuroglial progenitor cells [33]. Apoptosis is crucial during neuronal development by eliminating excess cells and ensuring proper synaptic connectivity [34, 35].

GCRs are known to be involved in Dex-induced apoptosis [36] and are present at high levels in the hippocampus where progenitor cells capable of dividing reside in the DG.

Our results showed increased apoptosis throughout the DG, suggesting that perinatal development in the hippocampus is vulnerable even to a single dose of Dex when given at a critical time. How this effect is related to the GCR density, receptor types, and the proliferation of progenitor cells remains to be studied.

It has been reported that administration of 3.0 mg/kg Dex to P7 mice increases the apoptosis of cerebellar progenitor cells and reduces the number of cerebellar neurons [37, 38]. It is likely that the dosage and timing of Dex treatment and...

N: number of pups.

Compared pups injected with dexamethasone (Dex) and normal saline (NS) by using Wilcoxon rank sum test, *P < 0.05.

D1D2: administration on postnatal day 1 and sacrificed on day 2; RU486: mifepristone; DMSO: dimethyl sulfoxide; DMSO/Dex: dimethyl sulfoxide plus dexamethasone; RU486/Dex: mifepristone plus dexamethasone.

Figure 1: TUNEL staining of dentate gyrus (DG) P1 D1D2 pups treated with dexamethasone (Dex) or normal saline (NS) shows apoptotic cells stained brown (arrows). The Dex-treated D1D2 DG had more apoptotic cells (b) than NS control (a). High magnification photomicrographs of TUNEL-positive cells are shown in the upper left corner. TUNEL-positive cell counts revealed that the number of apoptotic cells in the Dex-treated D1D2 DG was increased when compared to that of NS control pups (n = 6, *P < 0.05) (c). Cleaved-caspase 3 staining of the DG from P1 D1D2 pups with or without Dex treatment showed apoptotic cells (arrows) ((d) and (e)). High magnification photomicrographs of cleaved-caspase 3-positive cells are shown in the upper left corner. The numbers of apoptotic cells in Dex-treated pups were increased compared to those of NS control (f) (n = 6, *P < 0.05). Magnification, 200x; scale bars, 100 μm; inset magnification, 400x. P1 D1D2: P1 pups receiving treatment on postnatal day 1 and sacrificed on day 2.

vulnerability of neural progenitor cells to glucocorticoids together determine the effects on neonatal brain development.

Exposure to Dex in the neonatal period results in marked apoptosis among the nestin-expressing cells in the DG [39]. The importance of Dex-induced apoptosis in the hippocampus and the type of cells affected remain unknown. Our results from double staining in the Dex-treated pups showed higher ratios of cells coexpressing TUNEL and nestin to TUNEL-positive cells, indicating that Dex-induced apoptosis affects the neuroprogenitor cells. This result is consistent with previous reports that neuroprogenitor cells are sensitive to Dex during the early neonatal period [39, 40]. Since the ratio of TUNEL and NeuN coexpressing cells to TUNEL-positive cells also increased, Dex treatment might also cause apoptosis in mature neurons and be associated with a transient

FIGURE 3: TUNEL-positive cells were more numerous in the hippocampus of Dex-treated D1D2 pups than in control (n = 6, *P < 0.05) (a) and the ratio of TUNEL-positive cells which coexisted nestin to total TUNEL-positive cells was higher in the Dex treated than in the control groups (n = 6, *P < 0.05) (b). The ratio of TUNEL-positive cells coexpressing NeuN to total TUNEL-positive cells was higher than that of control (n = 6, *P < 0.05) (c). Dex-treated D1D2: P1 pups receiving dexamethasone on postnatal day 1 and sacrificed on day 2.

and acute slowing of cell proliferation during hippocampal
development [41, 42]. Whether these neurons were derived
from the proliferating progenitors cells or represent existing
mature neurons in the DG remains to be determined.

Mifepristone (or RU-486) is a synthetic steroid with
both antiprogesterone and antiglucocorticoid properties. In
a recent study, mifepristone was the only GCR antagonist
found to increase both mineralocorticoid receptor (MCR)
and GCR binding in the rat frontal cortex [43]. The effects
of mifepristone on corticosteroid receptor expression could
explain the neurocognitive improvement it is reported to
induce [43, 44]. RU486 has no effect on Dex regarding
thymocyte composition and maturation [45]. MCR-
mediated responses to glucocorticoids, rather than GCRs,
are important in steroid-responsive hearing disorders [46].
GCR activity levels are high in the hippocampus during the
first postnatal week [40]. The anti-inflammatory effects
of glucocorticoids require the presence of GCRs [47]. Interest-
ingly, results of these studies and those of our own
(60% reduction in Dex-induced apoptosis by RU486) are
consistent, suggesting that the type of receptor and the timing
of Dex treatment determine the effects of glucocorticoids on
the hippocampus. Examining pup brain tissues stained with
eosin/hematoxylin or IHC revealed no inflammatory cells
in the NS and Dex-treated D1D2 groups. These results suggest
that while GCRs are likely to be key players in Dex-induced
neuroprogenitor cell death, inflammatory cells are not.

In summary, brain development is a dynamic process in
which the growth spurt, differentiation, and cell responses to
endogenous (and exogenous) steroids occur at critical times.
Species differences add further complexity to the process.
These species-specific developmental schedules allowed the
design of animal models to study the effects of drug treat-
ment in preterm babies, as in this study. Here, we have
demonstrated that timing is a major factor in determining
Dex-induced apoptosis in the hippocampus, the vulnerable
cells are neuronal precursors, and the process is partly
regulated by GCRs. We also provided cytological evidence
that the administration of a single dose of Dex can result in
deleterious effects in the brain.
**Figure 4:** Dexamethasone (Dex) treatment increased levels of nuclear glucocorticoid receptors (GCRs), but not cytosolic GCRs, total brain-derived neurotrophic factor (BDNF) or total nestin in the hippocampus of P1 pups. (a) Representative western blots of hippocampal protein extracts obtained from P1 D1D2 pups, normal saline (NS, control) (left lane), and Dex (right lane). (b) Signals from BDNF, nestin, and cytosolic GCRs were normalized to actin and signals from nuclear GCRs were normalized to pCNA. Quantitative results showed no difference in BDNF, nestin, and cytosolic GCR expression between Dex-treated and control pups. The nuclear fraction of GCR expression in Dex-treated pups differed from control ($n = 6, *P < 0.05$). P1 D1D2: P1 pups receiving treatment on postnatal day 1 and sacrificed on day 2; white and black bars represent control and Dex-treated pups, respectively.

**Figure 5:** Dexamethasone-(Dex-) induced apoptosis in P1 D1D2 pups was reduced by preadministration of RU486. Dex treatment increased apoptotic cell counts in the hippocampus compared to control ($n = 6, *P < 0.05$); P1 D1D2 pups treated with DMSO or DMSO plus Dex showed results similar to those from pups treated with either normal saline (NS) or Dex alone ($n = 6, ^{†}P < 0.05$). RU486 treatment showed apoptotic cell counts similar to those from pups treated with NS or DMSO. Pups treated with RU486 plus Dex had lower apoptotic cell counts than those with Dex or DMSO plus Dex ($n = 6, ^{*}P < 0.05$). P1 D1D2: P1 pups receiving treatment on postnatal day 1 and sacrificed on day 2.
