(Received 18 April 1996)

Improvability theory for a simple assembly system consisting of two components and one assembly machine is developed. Both constrained and unconstrained formulations are addressed. In the constrained case, it is shown that the assembly is unimprovable with respect to workforce if each component machine is blocked as frequently as the assembly machine is starved for parts produced by this particular assembly machine. The system is unimprovable with respect to work-in-process if, roughly speaking, all buffers have equal average steady state occupancy. In the unconstrained improvability case, it is shown that the bottleneck machine can be identified by analyzing the probabilities of the so-called manufacturing blockages and starvations. A generalization to n component—one assembly machine system is also included.

Keywords: Improvability; assembly systems; bottlenecks; manufacturing blockage and starvation

1. INTRODUCTION

Assembly is a production system which includes the merging of parts produced. In most cases, it consists of two or more component machines, one or more assembly machines and, if necessary, additional processing machines. All the machines are separated by finite buffers. An example of

an assembly is shown in Figure 1, where m_{ij} , $i > 0$, are the component machines, m_{01} is the assembly machine, m_{0j} , $j > 1$, are the additional processing machines, and b_{ij} and b_{0j} are the buffers. Systems of this structure are the focus of this paper.

The idea of improvability for production systems was introduced in [1] to facilitate the development of quantitative engineering methods for design and implementation of continuous improvement projects on the factory floor. Roughly speaking, a production system is called improvable under constraints if limited resources involved in its operation (for instance, workforce—WF or work-in-process—WIP) can be re-distributed so that a performance index is improved. Unconstrained improvability addresses the question of constraints relaxation and, in particular, the identification of the machine improvement of which results in the best possible behavior of the system as a whole.

The properties of improvability under constraints for the simplest class of production systems—serial lines, where all machines are arranged in the consecutive order—have been investigated in [1], [2]. In particular, it has been shown that a serial line is unimprovable with respect to the WF if and only if all of its buffers are on the average half full. In other words, if some of the system's buffers are too full, the system can be improved; analogously, when some of the buffers are too empty; only when all the buffers are on the average half full (whatever the size of buffers may be), the system is unimprovable by re-assigning the existing WF. Also, it has been shown that a serial line is unimprovable with respect to WIP and WF simultaneously if and only if each machine is blocked and starved with equal probability. In a certain sense (see [2]), this condition holds

FIGURE 1 Assembly system.

also for improvability with respect to WIP. Thus, if some of the machines in the system are blocked more often than they are starved, the system is improvable; analogously, if some of the machines are more often starved than blocked; only when each machine is blocked and starved with equal frequency, the system is unimprovable by WIP re-allocation. Several extensions of this theory and a practical application have been reported in [3]–[5].

The unconstrained improvability for serial lines was analyzed in [2] and [6]. The bottleneck was defined as the machine which has the largest effect onto the overall system production rate. It was shown that in a system unimprovable with respect to WF, the slowest machine is always the bottleneck. Systems which are improvable with respect to WF may or may not have the slowest machine as the bottleneck. Sometimes other machines, including the fastest one, could be the bottleneck. In [6], a method for bottlenecks identification was developed, and it was shown that they can be identified by analyzing the probabilities of the so-called manufacturing blockages and starvations.

Although assembly systems have been a subject of many studies over the years (see [7], [8] and references therein) and heuristic algorithms for their performance analysis have been (relatively recently) developed ([9]–[11]), system-theoretic properties of these systems remain largely unknown. Two exceptions are reported in [12], [13], where the question of work and work-in-process distribution among the component machines and the assembly machine has been addressed. In particular, it has been shown that less work should be assigned to the assembly machine than to each of the component machines.

In this paper, we develop improvability theory for a simple assembly system consisting of two component and one assembly machine. Both constrained and unconstrained improvability are addressed. A generalization for n component machines, working in parallel, is also presented. The case of a more general systems, such as shown in Figure 1, will be described elsewhere.

The goal of the development presented here is not only to characterize the improvability properties of the assembly but also to accomplish this in terms of variables available on the factory floor. This should make the results obtained practical from the point of view of applications. Indeed, conditions formulated in terms which are either unfamiliar to practitioners or are not measurable on the factory floor could hardly find a receptive

audience among the production systems personnel. Only the conditions which are, on one hand, intuitively understandable and, on the other hand, use data available on the factory floor could realistically be expected to make an impact on the manufacturing practice. To this end, every condition derived in this work is re-formulated as an Improvability Indicator, i.e., a rule which, being based on real-time data, allows the production system personnel to identify whether the systems is improvable and to design steps for accomplishing this improvement.

The outline of the paper is as follows: In Section 2, the model of the system considered and the problem analyzed are formulated. In Section 3 an auxiliary result pertaining to the production rate calculation is described. Sections 4–6 and 7–8 are devoted to constrained and unconstrained improvability, respectively. A generalization for a system with n component machines is outlined in Section 9. The conclusions are given in Section 10. All the proofs are assembled in Appendices A–E.

Roughly speaking, the main results of this work are as follows:

(a). The assembly system is unimprovable with respect to WF if the probability of blockage of every component machine equals to the probability of starvation of the assembly machine caused by the lack of the parts produced by this component machine.

(b). The assembly system is unimprovable with respect to WIP if the average buffer occupancy of all buffers is as close to each other as possible.

(c). In an improvable system, if the probabilities of manufacturing blockage of the component machines are larger than the probability of manufacturing starvation of the assembly machine, the latter is the bottleneck; otherwise, one of the component machines is the bottleneck, and the rule for its identification is provided.

2. PROBLEM FORMULATION

2.1. The Model

The following model is considered throughout this work:

- (i) The system consists of component machines, m_i , $i = 1, 2$, an assem-

- bly machine, m_0 , and buffers, b_i , $i = 1, 2$, storing the parts produced by m_i , $i = 1, 2$, respectively; one part from each buffer is required for the assembly.
- (ii) All the machines have an identical cycle time, T ; the time axis is slotted with the slot duration T .
 - (iii) Each machine is characterized by the probability, p_i , $i = 0, 1, 2$, to produce a part during a time slot; these probabilities are referred to as machines' production rate in isolation.
 - (iv) Each buffer is characterized by its capacity, N_i , $i = 1, 2$; the buffer capacity is assumed to be finite.
 - (v) A component machines m_i , $i = 1, 2$, is never starved; it is blocked during a time slot if buffer b_i is full and the assembly machine, m_0 , fails to take a part from the buffer at the beginning of this time slot.
 - (vi) The assembly machine is never blocked; it is starved for parts, if at least one buffer b_i , $i = 1, 2$, is empty at the beginning of this time slot.

Remark 2.1: The generalization of this model to the case of $n > 2$ component machines (Section 9) is obvious: in all of the above assumptions use $i = 1, 2, \dots, n$, instead of $i = 1, 2$.

Remark 2.2: The assumption that only one part from each buffer is required for the assembly can be removed by an appropriate modification in the model. Basically, it does not restrict the generality.

Remark 2.3: On the other hand, the assumed Bernoulli model of machines reliability (assumption (iii)) is quite restrictive. In many practical situations, machines obey the Markovian, rather than the Bernoulli, reliability model, where the machines are characterized by exponentially distributed up- and down-time. As in [1]–[5], we use the Bernoulli model because, on one hand, there are assembly operations with machine' up-time process similar to a sequence independent trials and, on the other hand, this simpler model permits a more complete analytical investigation. We believe (and have a numerical evidence) that the results reported here hold qualitatively for the Markovian model as well. However, the extension of this theory to Markovian machines is the topic of the future work.

Remark 2.4: The synchronous operation, implied by (ii), is also assumed to simplify the analysis. Although somewhat restrictive, it is not unrealistic

for operations with automated material handling system which defines the assembly tact.

Remark 2.5: The assumption of a deterministic and fixed processing time (or cycle time) of the machines (see (ii)) does reflect the situation in most large volume production industries, with automated material handling or not. The often cited in the literature random processing time is not, in our opinion, appropriate in the context of such production systems.

2.2. Constrained Improvability

Assume that N_i 's and p_i 's are constrained as follows

$$N_1 + N_2 = N^*, \quad (2.1)$$

$$p_1 p_2 p_0 = p^*. \quad (2.2)$$

Obviously, (2.1) can be interpreted as WIP constraint: the total inventory in the system cannot exceed N^* . As in [1], [2], equality (2.2) is interpreted as WF (or machine efficiency) constraint: the total work that can be carried out in the system is bounded by p^* , and a reassignment of the workforce (or work) among the operations leads to changes in p_i 's compatible with (2.2).

DEFINITION 2.1: The assembly system (i)–(vi) is improvable with respect to WF if there exists a sequence p_0^*, p_1^*, p_2^* such that $p_1^* p_2^* p_0^* = p^*$ and

$$\widetilde{PR}(p_1^*, p_2^*, p_0^*, N_1, N_2) > \widetilde{PR}(p_1, p_2, p_0, N_1, N_2),$$

where $\widetilde{PR}$ denotes the production rate of the system, i.e., the average steady state number of parts produced by the assembly machine per cycle time.

DEFINITION 2.2: The assembly system (i)–(vi) is improvable with respect to WF and WIP simultaneously if there exist sequences p_0^*, p_1^*, p_2^* and N_1^*, N_2^* such that $p_1^* p_2^* p_0^* = p^*$, $N_1^* + N_2^* = N^*$ and

$$\widetilde{PR}(p_1^*, p_2^*, p_0^*, N_1^*, N_2^*) > \widetilde{PR}(p_1, p_2, p_0, N_1, N_2).$$

DEFINITION 2.3: The assembly system (i)–(vi) is improvable with respect to WIP if there exist N_1^* and N_2^* such that $N_1^* + N_2^* = N^*$ and

$$\widetilde{PR}(p_1, p_2, p_0, N_1^*, N_2^*) > \widetilde{PR}(p_1, p_2, p_0, N_1, N_2).$$

2.3. Unconstrained Improvability

When the system is no longer improvable under constraints or when the resource re-allocation, required by the improvability conditions, cannot be carried on the factory floor, a further increase in $\widetilde{PR}$ can be obtained only by the constraints relaxation, i.e., by increasing p^* or N^* . In practical terms, this amounts to the improvement of the machines isolation production rates (say, by improved preventative maintenance or by installing a more efficient machine) or by allocating additional in-process inventories to the system. The question arises: Which p_i or N_i should be increased so that the largest increase in $\widetilde{PR}$ is obtained? A formalization of this question is as follows:

DEFINITION 2.4: Machine m_i , $i = 0, 1, 2$, is the bottleneck machine if

$$\frac{\partial \widetilde{PR}}{\partial p_i} > \frac{\partial \widetilde{PR}}{\partial p_j}, \forall j \neq i.$$

DEFINITION 2.5: Buffer b_1 is the bottleneck buffer if

$$\widetilde{PR}(p_1, p_2, p_0, N_1 + 1, N_2) > \widetilde{PR}(p_1, p_2, p_0, N_1, N_2 + 1).$$

Buffer b_2 as the bottleneck is defined analogously.

Remark 2.6: In Definitions 2.1–2.5 and throughout this paper, the symbols with the “ $\sim$ ” denote the exact values of the appropriate quantity. The respective analytical approximation, to be introduced below, is denoted by the same symbol but without the “ $\sim$ ”.

Remark 2.7: Definitions 2.1–2.5 have obvious generalizations to the n component machines case: The sequences of three p_i ’s and two N_i ’s

should be replaced by sequences of p_i 's and N_j 's, with $i = 1, \dots, n + 1$; $j = 1, \dots, n$.

2.4. Problems

The goal of this paper is to derive conditions under which the assembly system (i)–(vi) is improvable in both constrained and unconstrained sense. As it was pointed out above, the conditions sought are to be formulated either in terms of the data available on the factory floor or in terms of the data that can be constructively calculated using the machines and buffers parameters, p_i 's and N_i 's. As in [1], [2], we refer to these conditions as Indicators of Improvability. The problems, then, addressed in this paper are:

Problem 1: Given model (i)–(vi), derive indicators of improvability with respect to WF, WIP, and WF and WIP simultaneously which could be used based on either measured or calculated data.

Problem 2: Given model (i)–(vi), derive indicators of improvability for bottleneck identification which are based on real-time or calculated data.

Solutions of Problems 1 and 2 are given in Sections 4–6 and 7–8, respectively. In the unconstrained case, only the notion of bottleneck machines is analyzed; the problem of bottleneck buffers will be addressed elsewhere.

3. PRODUCTION RATE EVALUATION

This section presents auxiliary results used below to provide an analytical solution to Problems 1 and 2.

Under assumption (i)–(vi), the dynamics of the assembly system are described by an irreducible, ergodic Markov chain with the states (k_1, k_2) , $k_i = 1, \dots, N_i$, $i = 1, 2$. Let $\tilde{X}_{1,2}(k_1, k_2)$ be the stationary probability that buffers b_1 and b_2 have k_1 and k_2 parts, respectively. In terms of $\tilde{X}_{1,2}(k_1, k_2)$, the production rate of the system is:

$$\begin{aligned}
 \widetilde{PR} &= p_0 \sum_{k_2=1}^{N_2} \sum_{k_1=1}^{N_1} \tilde{X}_{1,2}(k_1, k_2) \\
 &= p_0 [1 - \tilde{X}_{1,2}(0, 0) - \sum_{k_1=1}^{N_1} \tilde{X}_{1,2}(k_1, 0) - \sum_{k_2=1}^{N_2} \tilde{X}_{1,2}(0, k_2)].
 \end{aligned} \tag{3.1}$$

Unfortunately, $\tilde{X}_{1,2}(k_1, k_2)$ cannot be calculated in the closed form. Therefore, a simplification is necessary. One possibility is to reduce the joint probability distribution to the product of its marginals. In general, of course, the joint probability distribution $\tilde{X}_{1,2}(k_1, k_2)$ is not equal to the product of its marginals, $\tilde{X}_1(k_1)$ and $\tilde{X}_2(k_2)$. However, when either k_1 or k_2 or both are 0, these two quantities are close to each other in the following sense: Introduce

$$\mu_1(k_1) := |\tilde{X}_{1,2}(k_1, 0) - \tilde{X}_1(k_1)\tilde{X}_2(0)|, \quad k_1 = 0, \dots, N_1,$$

$$\mu_2(k_2) := |\tilde{X}_{1,2}(0, k_2) - \tilde{X}_1(0)\tilde{X}_2(k_2)|, \quad k_2 = 0, \dots, N_2,$$

$$\mu := \max_{k_1, k_2} \{\mu_1(k_1), \mu_2(k_2)\}.$$

NUMERICAL FACT 3.1: *For the assembly system defined by assumptions (i)–(vi),*

$$\mu << 1.$$

Justification: Justification is carried out using numerical analysis of the Markov chain defined by assumptions (i)–(vi). Specifically, the transition matrix has been constructed and iterated upon until the stationary probability distribution, $\tilde{X}_{1,2}(k_1, k_2)$, has been reached. The $\tilde{X}_{1,2}(k_1, 0)$ and $\tilde{X}_{1,2}(0, k_2)$, thus calculated, have been compared with the products of their marginals $\tilde{X}_1(k_1)\tilde{X}_2(0)$ and $\tilde{X}_1(0)\tilde{X}_2(k_2)$, where

$$\tilde{X}_1(k_1) = \sum_{k_2=0}^{N_2} \tilde{X}_{1,2}(k_1, k_2),$$

$$\tilde{X}_2(k_2) = \sum_{k_1=0}^{N_1} \tilde{X}_{1,2}(k_1, k_2).$$

Finally, the value of μ has been calculated. In every case analyzed, it was found that $\mu \ll 1$. Several typical example are shown in Table I. Based on this evidence, we conclude that Numerical Fact 3.1 holds.

Remark 3.1: We believe that Numerical Fact 3.1 can be proved analytically. Up to now, however, we were unable to do so. The readers are certainly encouraged to attempt such a proof.

Using Numerical Fact 3.1, expression (3.1) can be rewritten as follows:

$$\begin{aligned} \widetilde{PR} &= p_0[1 - \tilde{X}_1(0)\tilde{X}_2(0) - \sum_{k_1=1}^{N_1} \tilde{X}_1(k_1)\tilde{X}_2(0) \\ &\quad - \sum_{k_2=1}^{N_2} \tilde{X}_1(0)\tilde{X}_2(k_2)] + \mathcal{O}(\mu) \\ &= p_0[1 - \tilde{X}_1(0)\tilde{X}_2(0) - (1 - \tilde{X}_1(0))\tilde{X}_2(0) \\ &\quad - \tilde{X}_1(0)(1 - \tilde{X}_2(0))] + \mathcal{O}(\mu). \end{aligned}$$

Therefore,

$$\widetilde{PR} = p_0[1 - \tilde{X}_1(0)][1 - \tilde{X}_2(0)] + \mathcal{O}(\mu). \quad (3.2)$$

The quantities $\tilde{X}_1(0)$ and $\tilde{X}_2(0)$, i.e., the probabilities that buffers b_1 and b_2 are empty, still cannot be calculated in the closed form. However, a recursive evaluation is possible. Indeed, assume that the estimate of the

TABLE I Illustration of μ and the estimation error

p_1	p_2	p_0	N_1	N_2	μ	$\widetilde{PR}$	PR	$\frac{ \widetilde{PR} - PR }{\widetilde{PR}} \cdot 100\%$
								$\widetilde{PR}$
0.7	0.6	0.8	1	1	0.0032	0.4527	0.4512	0.3%
0.8	0.7	0.8	1	2	0.0024	0.598	0.5974	0.1%
0.7	0.6	0.8	2	2	0.0108	0.5492	0.5537	0.8%
0.6	0.6	0.99	3	3	0.029	0.5584	0.5856	4.9%
0.9	0.9	0.6	2	2	0.0013	0.5893	0.589	0.05%

probability that b_2 is empty at the s -th step of the recursion is known; denote this probability as $X_2(0, s)$. Consider the serial line $\{m_1, b_1, m_0\}$ (see Figure 2) with the isolation production rate of machines m_1 and m_0 defined as p_1 and $p_0[1 - X_2(0, s)]$, respectively. For this line, using the results of [1], it is easy to calculate the probability that b_1 is empty. Specifically, this probability is $Q(p_1, p_0[1 - X_2(0, s)], N_1)$, where function $Q(x, y, N)$ is defined below and N_1 is the capacity of b_1 . Denote this probability as $X_1(0, s + 1)$ and consider another serial line, $\{m_2, b_2, m_0\}$, with the isolation production rate of m_2 and m_0 given by p_2 and $p_0[1 - X_1(0, s + 1)]$, respectively. Again, calculate the probability that b_2 is empty and, thus, obtain $X_2(0, s + 1)$. As a result, we obtain the following recursive procedure:

$$X_1(0, s + 1) = Q(p_1, p_0[1 - X_2(0, s)], N_1), \quad (3.3)$$

$$X_2(0, s + 1) = Q(p_2, p_0[1 - X_1(0, s + 1)], N_2),$$

$$X_2(0, 0) = 0, s = 0, 1, 2, \dots,$$

where

$$Q(x, y, N) = \begin{cases} \frac{(1-x)(1-\alpha)}{1 - \frac{x}{y}\alpha^N}, & x \neq y, \\ \frac{1-x}{N+1-x}, & x = y, \end{cases} \quad \alpha = \frac{x(1-y)}{y(1-x)}.$$

LEMMA 3.1: *Recursive procedure (3.3) is convergent, i.e., the following limits exist:*

FIGURE 2 Two component—one assembly machine system.

$$\lim_{s \rightarrow \infty} X_1(0, s) =: X_1(0),$$

$$\lim_{s \rightarrow \infty} X_2(0, s) =: X_2(0).$$

Moreover, sequences $X_1(0, s)$ and $X_2(0, s)$ are monotonically decreasing and increasing, respectively.

Proof: See Appendix A.

The relationship between the exact, $\tilde{X}_i(0)$, and the calculated, $X_i(0)$, probabilities of the buffers being empty is given by

THEOREM 3.1: *For assembly lines defined by assumptions (i)–(vi),*

$$\begin{aligned}\tilde{X}_1(0) &= X_1(0) + \mathbb{O}(\mu), \\ \tilde{X}_2(0) &= X_2(0) + \mathbb{O}(\mu).\end{aligned}\tag{3.4}$$

Proof: See Appendix A.

Introduce the production rate estimate as follows:

$$PR := p_0[1 - X_1(0)][1 - X_2(0)],\tag{3.5}$$

where $X_1(0)$ and $X_2(0)$ are the steady states of (3.3).

COROLLARY 3.1: *For the assembly system defined by assumptions (i)–(vi),*

$$\widetilde{PR} = PR + \mathbb{O}(\mu).$$

Proof: Follows immediately from (3.2), (3.4) and (3.5).

The numerical accuracy of the calculated production rate, defined by (3.5), is illustrated in Table I, where both $\widetilde{PR}$ and PR are shown along with the approximation error. All cases analyzed resulted in a high accuracy, with 0.05%–5% error. Based upon this evidence, the improvability analysis described in this paper is carried out in terms of the calculated production rate, PR , defined by (3.3), (3.5).

To conclude this Section, we cite two more auxiliary results. The first one is concerned with the relationship between the exact and the calcu-

lated steady state occupancies of buffers b_1 and b_2 and the second describes the monotonicity properties of the assembly system.

Let

$$\tilde{X}_i(k_i) = \text{Prob}\{b_i \text{ has } k_i \text{ parts in the steady state}\}, k_i = 1, \dots, N_i, i = 1, 2.$$

Introduce

$$X_1(k_1) = X_1(0) \left(\frac{1}{1 - p_0[1 - X_2(0)]} \right) \alpha_1^{k_1}, k_1 = 1, \dots, N_1, \quad (3.6)$$

$$X_2(k_2) = X_2(0) \left(\frac{1}{1 - p_0[1 - X_1(0)]} \right) \alpha_2^{k_2}, k_2 = 1, \dots, N_2,$$

where $X_1(0)$, $X_2(0)$ are the steady states of (3.3) and

$$\alpha_1 = \frac{p_1(1 - p_0[1 - X_2(0)])}{p_0[1 - X_2(0)](1 - p_1)}, \alpha_2 = \frac{p_2(1 - p_0[1 - X_1(0)])}{p_0[1 - X_1(0)](1 - p_2)}.$$

COROLLARY 3.2: *For the assembly system defined by assumptions (i)–(vi),*

$$\tilde{X}_i(k_i) = X_i(k_i) + \mathcal{O}(\mu), k_i = 1, \dots, N_i, \quad i = 1, 2.$$

Proof: See Appendix A.

COROLLARY 3.3: *The calculated production rate, $PR(p_1, p_2, p_0, N_1, N_2)$, defined by (3.3), (3.5), is a monotonically increasing function of all its arguments.*

Proof: See Appendix A.

The monotonicity property of the assembly system cited above is quite similar to that established in [14]–[15].

4. IMPROVABILITY WITH RESPECT TO WF

4.1. Improvability Conditions

In terms of the calculated production rate, assembly system (i)–(vi) is improvable with respect to WF if there exist p_0^*, p_1^*, p_2^* such that $p_1^* p_2^* p_0^* = p^*$ and

$$PR(p_1^*, p_2^*, p_0^*, N_1, N_2) > PR(p_1, p_2, p_0, N_1, N_2).$$

THEOREM 4.1: *Assembly system (i)–(vi) is unimprovable with respect to WF if and only if*

$$\begin{aligned} p_1 &= p_0[1 - X_2(0)], \\ p_2 &= p_0[1 - X_1(0)]. \end{aligned} \quad (4.1)$$

where $X_i(0)$, $i = 1, 2$, is the steady state of the recursive procedure (3.3).

Proof: See Appendix B.

To reformulate condition (4.1) in terms of the data available on the factory floor, let $\widetilde{cb}_i$, $i = 1, 2$, denote the probability of the so-called **communication blockage** of the component machine i :

$$\widetilde{cb}_i = \text{Prob}\{b_i \text{ is full and } m_0 \text{ fails to take parts from } b_i\}, i = 1, 2.$$

Let $\widetilde{cs}_i$, $i = 1, 2$, denote the probability of the **communication starvation** of the assembly machine m_0 due to the lack of parts produced by the component machine i :

$$\widetilde{cs}_i = \text{Prob}\{b_i \text{ is empty}\}, i = 1, 2.$$

Finally, let $\widetilde{h}_i$, $i = 1, 2$, denote the average steady state occupancy of buffer b_i .

COROLLARY 4.1: *Under condition (4.1),*

(a).

$$\widetilde{cb}_i = \widetilde{cs}_i + \mathcal{O}(\mu), i = 1, 2;$$

(b).

$$\widetilde{h}_i = E[\widetilde{h}_i] = \frac{N_i}{2} \frac{N_i + 1}{N_i + 1 - p_i} + \mathcal{O}(\mu) \approx \frac{N_i}{2}, i = 1, 2.$$

Proof: See Appendix B.

Since, as it is stated in Corollaries 3.1 and 3.2, the exact and the calculated production rates and buffer occupancies are $\mathcal{O}(\mu)$ close to each other, from Corollary 4.1 follows

IMPROVABILITY INDICATOR 4.1: *Assembly system (i)–(vi) is unimprovable with respect to WF if the frequency of communication blockage of a component machine is close to the frequency of communication starvation of the assembly machine caused by the lack of parts produced by this component machine; when this situation takes place, each buffer is on the average almost half full.*

Remark 4.1: Improvability indicator 4.1 can be rationalized as follows: Buffer b_1 protects m_1 from blockages and m_0 from starvations due to parts produced by m_1 . From the point of view of m_1 , buffer b_1 should be mostly empty; from the point of view of m_0 , buffer b_1 should be mostly full. The compromise is: buffer half full or blockages equal starvations. This is accomplished by distributing p^* in an unimprovable manner.

4.2. Unimprovable Distribution of p^*

Using improvability indicator 4.1, one could determine how good the assembly system is with regard to WF distribution. This does not require the knowledge of the machines and buffers parameters, p_i 's and N_i 's. If, however, N_i 's are known, the unimprovable value of p_i 's can be calculated as follows:

Let PR^* denote the production rate of the system under the best possible distribution of p_i 's, i.e.,

$$PR^* = \max_{p_1 p_2 p_0 = p^*} PR(p_1, p_2, p_0, N_1, N_2). \quad (4.2)$$

Introduce the recursive procedure:

$$x(s+1) = (p^*)^{\frac{1}{3}} \left(\frac{N_1 + x(s)}{N_1 + 1} \right)^{\frac{2}{3}} \left(\frac{N_2 + x(s)}{N_2 + 1} \right)^{\frac{2}{3}}. \quad (4.3)$$

THEOREM 4.2: Assume $\frac{1}{N_1} + \frac{1}{N_2} \leq \frac{3}{2}$. Then the recursive procedure (4.3) is a contraction on $[0, 1]$. Moreover,

$$\lim_{s \rightarrow \infty} x(s) = PR^*,$$

where PR^* is defined by (4.2). In addition, the values of p_i , $i = 0, 1, 2$, that result in PR^* are:

$$\begin{aligned} p_i^* &= \left(\frac{N_i + 1}{N_i + PR^*} \right) PR^*, \quad i = 1, 2, \\ p_0^* &= \left(\frac{N_1 + 1}{N_1 + PR^*} \right) \left(\frac{N_2 + 1}{N_2 + PR^*} \right) PR^*. \end{aligned} \quad (4.4)$$

Proof: See Appendix B.

Remark 4.2: Since, as it follows from the above $p_0^*/p_i^* > 1$, Theorem 4.2 confirms the conclusion, established in [12], concerning the bowl phenomenon for the assembly systems.

5. IMPROVABILITY WITH RESPECT TO WF AND WIP SIMULTANEOUSLY

5.1. Improvability Conditions

In terms of the calculated production rate, the assembly system (i)–(vi) is improvable with respect to WF and WIP simultaneously if there exist p_0^* , p_1^* , p_2^* and N_1^* , N_2^* such that $p_1^* p_2^* p_0^* = p^*$, $N_1^* + N_2^* = N^*$ and

$$PR(p_1^*, p_2^*, p_0^*, N_1^*, N_2^*) > PR(p_1, p_2, p_0, N_1, N_2).$$

THEOREM 5.1: Assembly system (i)–(vi) is unimprovable with respect to WF and WIP simultaneously if and only if (4.1) takes place and, in addition,

$$X_1(0) = X_2(0). \quad (5.1)$$

where, as before, $X_i(0)$, $i = 1, 2$, is the steady state of the recursive procedure (3.3).

Proof: See Appendix C.

COROLLARY 5.1: Under conditions (4.1) and (5.1),

$$\bar{h}_1 = \bar{h}_2 + \mathcal{O}(\mu), \quad (5.2)$$

where $\bar{h}_i$, $i = 1, 2$, is the average steady state occupancy of buffer b_i .

Proof: See Appendix C.

From Corollaries 4.1 and 5.1 follows

IMPROVABILITY INDICATOR 5.1: Assembly system (i)–(vi) is unimprovable with respect to WF and WIP simultaneously if each buffer is on the average close to being half full and the average occupancy of each buffer is almost the same.

Remark 5.1: A rationalization of Improvability indicator 5.1 can be given as follows: Buffers b_1 and b_2 protect m_0 from starvations for parts produced by m_1 and m_2 , respectively. When $\bar{h}_1 > \bar{h}_2$, a unit of the capacity of b_1 can be reallocated to b_2 so that the starvation of m_0 for parts produced by m_2 is reduced and, consequently, PR is increased. Only when $\bar{h}_1 \approx \bar{h}_2$, machine m_0 is protected equally from the starvations for each part type and, therefore, the system is unimprovable.

5.2 Unimprovable Distribution of p^* and N^*

The values of p_i^* , $i = 0, 1, 2$, and N_j^* , $j = 1, 2$, which render the system unimprovable with respect to WF and WIP can be calculated as follows:

THEOREM 5.2: Assume that N^* is even and denote

$$PR^{**} = \max_{\substack{p_1, p_2, p_0; p_1 p_2 p_0 = p^* \\ N_1, N_2; N_1 + N_2 = N^*}} PR(p_1, p_2, p_0, N_1, N_2).$$

Then conditions (4.1) and (5.1) are satisfied if and only if,

$$\begin{aligned}
 p_i^* &= \left(\frac{\frac{N^*}{2} + 1}{\frac{N^*}{2} + PR^*} \right) PR^*, i = 1, 2, \\
 p_0^* &= \left(\frac{\frac{N^*}{2} + 1}{\frac{N^*}{2} + PR^*} \right)^2 PR^*, \\
 N_i^* &= \frac{N^*}{2},
 \end{aligned} \tag{5.3}$$

where PR^{**} is calculated according to recursive procedure (4.3) with N_i 's defined by (5.3).

Proof: See Appendix C.

Thus, in an assembly system unimprovable with respect to both WF and WIP buffers b_1 and b_2 are of equal capacity and $p_1 = p_2 < p_0$, as indicated in (5.3).

6. IMPROVABILITY WITH RESPECT TO WIP

In terms of the calculated production rate, assembly system (i)–(vi) is improvable with respect to WIP if there exist N_1^* and N_2^* such that $N_1^* + N_2^* = N^*$ and

$$PR(p_1, p_2, p_0, N_1^*, N_2^*) > PR(p_1, p_2, p_0, N_1, N_2).$$

Unfortunately, no simple analytical criteria for improvability with respect to WIP have been found. However, motivated by condition (5.2), we formulate the rule given below and justify it by numerical analysis of the Markov chain.

IMPROVABILITY INDICATOR 6.1: *Assembly system (i)–(vi) is unimprovable with respect to WIP if the average occupancy of b_1 is as close as possible*

to that of b_2 , i.e., $|\bar{h}_1 - \bar{h}_2|$ is minimized over all N_1 and N_2 such that $N_1 + N_2 = N^*$.

Remark 6.1: Recall that sign “ $\sim$ ” indicates that $\bar{h}_i$ is the exact (rather than calculated h_i) occupancy of buffer b_i , $i = 1, 2$.

Numerical Justification: For all systems considered, transition matrices have been constructed, stationary probabilities of all states have been calculated, and the average occupancies of buffers have been evaluated. A typical example is shown in Table II. Obviously, $\max \widetilde{PR}$ takes place if $|\bar{h}_1 - \bar{h}_2|$ is minimized. Similar results have been obtained in the majority of cases analyzed. Several counterexamples, however, have also been found. One of them is shown in Table III. Although in this example $\min |\bar{h}_1 - \bar{h}_2|$ does not result in the $\max \widetilde{PR}$, the difference between $\max \widetilde{PR}$ and the $\widetilde{PR}$ corresponding to $\min |\bar{h}_1 - \bar{h}_2|$ is quite small. A similar situation was observed in every case where the above rule failed. Therefore, we conclude that Improvability indicator 6.1 results in either the best or “almost” the best WIP distribution.

Remark 6.2: The unimprovable distribution of N_1 and N_2 can be reached not only through the complete search as in Tables II and III but also using the following **Algorithm**: Estimate $\bar{h}_1 - \bar{h}_2$; re-allocate a unit of the buffer capacity from N_1 to N_2 if this difference is positive and from N_2 to N_1 if it is negative; continue this process until a periodic cycle of length 2 is reached; choose N_1 and N_2 from the values on the cycle that give the largest $\widetilde{PR}$; stop. The performance of this algorithm in comparison with the complete search procedure is illustrated in Table IV: In all case analyzed, it resulted in the same distribution of N_i 's as the complete search approach.

TABLE II Illustration of Improvability indicator 6.1 ($p_1 = 0.8$, $p_2 = 0.5$, $p_0 = 0.5$, $N_1 + N_2 = 6$)

N_1	N_2	$\bar{h}_1$	$\bar{h}_2$	$ \bar{h}_1 - \bar{h}_2 $	$\widetilde{PR}$
5	1	4.8746	0.6667	4.2079	0.3333
4	2	3.8177	1.2002	2.6175	0.4
3	3	2.7891	1.7191	1.07	0.4281
2	4	1.7987	2.285	0.4863	0.4406
1	5	0.8938	3.2781	2.3843	0.4249

TABLE III Counterexample for Improvability indicator 6.1 ($p_1 = 0.7, p_2 = 0.6, p_0 = 0.8, N_1 + N_2 = 6$)

N_1	N_2	$\bar{h}_1$	$\bar{h}_2$	$ \bar{h}_1 - \bar{h}_2 $	$\overline{PR}$
5	1	4.2565	0.6534	3.6031	0.5199
4	2	3.0152	0.9526	2.0626	0.5692
3	3	2.0881	1.2351	0.853	0.5796
2	4	1.3521	1.6724	0.3203	0.5792
1	5	0.7607	2.7529	1.9922	0.5583

TABLE IV Implementation of Improvability indicator 6.1 based on the complete search and the Algorithm ($N_1 + N_2 = 6$)

p_1	p_2	p_0	Algorithm		Complete search	
			N_1	N_2	N_1	N_2
0.7	0.6	0.5	3	3	3	3
0.7	0.6	0.65	3	3	3	3
0.7	0.6	0.8	3	3	3	3
0.8	0.5	0.5	2	4	2	4
0.8	0.5	0.65	2	4	2	4
0.8	0.5	0.8	2	4	2	4

Remark 6.3: In the case of improvability with respect to WF and WIP simultaneously, the exact equality of the average buffer occupancies is possible due to the infinitesimal nature of the distribution of p_i 's; this counteracts the discrete nature of the distribution of N_i 's. Since in the case of improvability with respect to WIP only the p_i 's are fixed, no equality of $\bar{h}_1$ and $\bar{h}_2$ can, in general, be reached. Only the minimization of the difference $|\bar{h}_1 - \bar{h}_2|$ could be achieved, and the N_i 's that result in this minimization are, according to the Improvability indicator 6.1, the unimprovable values of WIP distribution.

7. UNCONSTRAINED IMPROVABILITY: WF UNIMPROVABLE SYSTEMS

According to Definition 2.4, m_i is the bottleneck of the assembly system if

$$\frac{\partial PR}{\partial p_i} > \frac{\partial PR}{\partial p_j}, \forall j \neq i.$$

As it has been pointed out in Section 2, a machine with the smallest p_i is not necessarily the bottleneck. An example is given in Figure 3, where m_2 has the smallest p_i but m_1 has the largest $\partial PR/\partial p_i$. In Figure 3 and all the subsequent figures, the numbers in the circles and the rectangles represent the machines' and buffers' parameters, p_i and N_i , respectively, and the numbers under the machines are the estimates of $\partial PR/\partial p_i$ denoted as $\Delta \widetilde{PR}/\Delta p_i$ and calculated using the numerical Markov chain analysis.

It turns out, however, that if the assembly is unimprovable with respect to WF, the machine with the smallest p_i is indeed the bottleneck. This follows from

THEOREM 7.1: *If assembly system (i)–(vi) is unimprovable with respect to WF, then*

$$p_1 \frac{\partial PR}{\partial p_1} = p_2 \frac{\partial PR}{\partial p_2} = p_0 \frac{\partial PR}{\partial p_0}. \quad (7.1)$$

Proof: See Appendix D.

Equalities (7.1) imply that the smallest p_i has the largest $\partial PR/\partial p_i$. Therefore,

IMPROVABILITY INDICATOR 7.1: *To expose the bottleneck machine, first ensure that the system is unimprovable with respect to WF; then, the machine with the smallest production rate in isolation is the bottleneck.*

FIGURE 3 The bottleneck example.

8. UNCONSTRAINED IMPROVABILITY: THE GENERAL CASE

8.1. Preliminaries

Most production systems on the factory floor are, unfortunately, improvable and often cannot be made unimprovable due to practical limitations. Therefore, it is of importance to identify bottlenecks in improvable systems. In many cases this is the only way for continuous improvements. This section is devoted to this topic.

Generally speaking, bottleneck machine of any assembly, improvable or not, can be determined by calculating $\partial \widetilde{PR} / \partial p_i$ and selecting m_i corresponding to its largest value. Unfortunately, however, the calculation of $\partial \widetilde{PR} / \partial p_i$ is a difficult, if not an impossible, proposition. As it has been pointed out above, in the case of unimprovable systems this calculation is unnecessary: the slowest machine is always the bottleneck. Is there a way to identify bottlenecks in improvable systems without calculating $\partial \widetilde{PR} / \partial p_i$? It turns out that the answer is positive, and a way for such an identification is described below.

Let $\widetilde{mb}_i$ and $\widetilde{ms}_i$ denote the probabilities of the **manufacturing blockage** of the component machine i , $i = 1, 2$, and the **manufacturing starvation** of the assembly machine m_0 due to the lack of parts produced by the component machine i , $i = 1, 2$, respectively, i.e.,

$$\widetilde{mb}_i = \text{Prob} (\{m_i \text{ is up during a time slot} \}$$

$$\cap \{b_i \text{ is full at the beginning of this slot} \}$$

$$\cap \{m_0 \text{ fails to take a part from } b_i \text{ at the beginning of this slot} \}), i = 1, 2,$$

$$\widetilde{ms}_i = \text{Prob} (\{m_0 \text{ is up during a time slot} \}$$

$$\cap \{b_i \text{ is empty at the beginning of this slot} \}), i = 1, 2.$$

We show below that bottlenecks in improvable systems can be identified by analyzing the relationships between the values $\widetilde{mb}_i$ and $\widetilde{ms}_i$ for each pair of consecutive machines.

8.2. The Case of a Single Bottleneck

Consider an assembly shown in Figure 4(a). The two numbers under each component machine represent $\widetilde{mb}_i$ and an estimate of $\partial \widetilde{PR}/\partial p_i$ denoted as $\Delta \widetilde{PR}/\Delta p_i$. The assembly machine has three numbers, with $\widetilde{ms}_1$ and $\widetilde{ms}_2$ representing the probability of starvations due to the lack of part in b_1 and b_2 , respectively, and $\Delta \widetilde{PR}/\Delta p_0$. Obviously, m_1 and m_2 are never starved and m_0 is never blocked; this is not represented in Figure 4. To identify the bottleneck machine, place arrows directed from one machine to another according to the following:

FIGURE 4 Illustration of Improbability indicator 8.1.

RULE 8.1: If $\widetilde{mb}_i > \widetilde{ms}_i$, the arrow is directed from the upstream to the downstream machine; if $\widetilde{mb}_i < \widetilde{ms}_i$, the direction of the arrow is reversed.

The following improvability indicator identifies the bottleneck machine if it is unique. The case of multiple bottlenecks is addressed in Subsection 8.3.

IMPROVABILITY INDICATOR 8.1: Assume that assembly system (i)–(vi) has a unique machine which has no arrows emanating from it. Then this machine is the bottleneck.

Thus, according to this indicator, the bottleneck of an assembly can be identified without calculating $\partial \widetilde{PR} / \partial p_i$, or even without the knowledge of the machines and buffers parameters, p_i 's and N_i 's, but just by observing the frequencies of blockages and starvations of the machines. Since these frequencies often are or can be measured on the factory floor, this indicator offers a constructive way for bottleneck identification.

Improvability indicator 8.1 is justified below both numerically and analytically.

Numerical Justification: The transition matrix for the Markovian chain defined by assumptions (i)–(vi) has been constructed and iterated upon to obtain stationary probability distributions for p_i and $p_i + \Delta p_i$, with the step $\Delta p_i = 0.01$. Then, the difference between the resulting production rates, $\Delta \widetilde{PR}$, has been calculated and $\Delta \widetilde{PR} / \Delta p_i$ has been evaluated. Two typical examples are shown in Figure 4. According to Improvability indicator 8.1, the bottleneck is the machine without arrows emanating from it. Hence, the bottlenecks in Figure 4(a) and (b) are component machine m_1 and assembly machine m_0 , respectively. This conclusion is supported by the values of $\Delta \widetilde{PR} / \Delta p_i$.

For most systems considered the bottleneck identified using Improvability indicator 8.1 and $\Delta \widetilde{PR} / \Delta p_i$ coincides. An example in which the two results differ is shown in Figure 5: According to Improvability indicator 8.1, the bottleneck is m_0 whereas according to $\Delta \widetilde{PR} / \Delta p_i$ the bottleneck is m_1 . However, as it can be seen in Figure 5, the difference between $\Delta \widetilde{PR} / \Delta p_1$ and $\Delta \widetilde{PR} / \Delta p_0$ is quite small. The same situation has been observed in all counterexamples discovered. Therefore, we conclude that Improvability indicator 8.1 identifies either the machine with the largest $\partial \widetilde{PR} / \partial p_i$ or a machine with $\partial \widetilde{PR} / \partial p_i$ being close to the largest one.

FIGURE 5 Counterexample for Improvability indicator 8.1.

Analytical Justification: An additional assumption is needed to carry out the analytical proof:

Hypothesis 8.1: In assembly system (i)–(vi), if

$$mb_j > ms_j, j = 1, 2,$$

then

$$X_j(0) \approx Q(p_j, p_0[1 - X_{3-j}(0)], N_j) =: \epsilon_{j1} < 1; \quad (8.1)$$

if

$$mb_j < ms_j, j = 1, 2,$$

then

$$(1 - p_0[1 - X_{3-j}(0)])X_j(N_j) \approx Q(p_0[1 - X_{3-j}(0)], p_j, N_j) =: \epsilon_{j2} < 1. \quad (8.2)$$

Here $X_j(0)$ and $X_j(N_j)$ are the stationary probabilities that buffer $b_j, j = 1, 2$, is empty and full respectively, and function $Q(x, y, N)$ is defined in (3.3).

Expression (8.1) implies that if a component machine is blocked more often than the assembly machine is starved due to parts produced by this component machine, the probability that the buffer separating these two

machines, is empty is small. Similarly, (8.2) implies that if a component machine is blocked less frequently than the assembly machine is starved, the probability that the buffers is full is small. Hypothesis 8.1 has been formulated based on numerical evidence obtained in simulations.

THEOREM 8.1: *Assume that system (i)–(vi) has a unique machine m_i , $i \in \{0, 1, 2\}$, with no arrows emanating from it. Then, under Hypothesis 8.1, m_i is the bottleneck in the sense that*

$$\frac{\partial PR}{\partial p_i} > \frac{\partial PR}{\partial p_j}, \forall j \neq i.$$

Proof: See Appendix E.

8.3. Multiple Bottlenecks

Assume now that the assembly system has two machines with no arrows emanating from them. Under the Rule 8.1, these could be only the two component machines. Which one, then, is the bottleneck? To answer this question, introduce the notion of a bottleneck severity:

$$\tilde{S}_i = \widetilde{ms}_i - \widetilde{mb}_i, i = 1, 2.$$

IMPROVABILITY INDICATOR 8.2: *If the assembly system (i)–(vi) has both component machines with no arrows emanating from them, the one with the largest severity is the primary bottleneck, i.e. defines the largest $\partial \widetilde{PR} / \partial p_i$.*

Numerical Justification: Improvability indicator 8.2 has also been justified using the direct numerical Markov chain analysis. Two typical examples are shown in Figure 6, where the last row of numbers is the bottleneck severity. In most cases analyzed, Improvability indicator 8.2 resulted in the correct identification of the primary bottleneck. A number of counterexamples have also been found. One of them is shown in Figure 7. Nevertheless, since in the majority of cases analyzed Improvability indicator 8.2 identified the machine with the best possible effect on the production rate, we conclude that it can be employed as a tool for the primary bottleneck identification.

(a)

(b)

FIGURE 6 Illustration of Improvability indicator 8.2.

9. THE CASE OF n COMPONENT—ONE ASSEMBLY MACHINE SYSTEM

Results described in Sections 3–8 can be generalized for the case of the assembly that consists on n component machines working in parallel and one assembly machine (Figure 8). Such a system is defined by assumptions (i)–(vi) with obvious changes pertaining to the number of the component machines (see Remark 2.1). The notions of improvability also remain the same with obvious changes in Definitions 2.1–2.5 (Remark 2.7). Below, we

FIGURE 7 Counterexample for Improvability indicator 8.2.

FIGURE 8 n component—one assembly machine system.

cite main results on improbability of such a system. The proofs are straightforward generalizations of those given in Appendices A–E and are not included here.

9.1. Production Rate Evaluation

Using arguments similar to those described in Section 3, the production rate, $\widetilde{PR}$, of the assembly systems with n component machines is represented as

$$\widetilde{PR} = p_0 \prod_{i=1}^n [1 - \tilde{X}_i(0)] + \mathcal{O}(\mu).$$

where p_0 is the isolation production rate of the assembly machine, $\tilde{X}_i(0)$, $i = 1, \dots, n$, is the steady state probability of buffer i being empty, and $\mu \ll 1$. The analytical approximations of $\tilde{X}_i(0)$ are obtained through the following recursive procedure:

$$X_i(0, s+1) = Q(p_1, p_0 \prod_{j=1}^{i-1} [1 - X_j(0, s+1)] \prod_{j=i+1}^n [1 - X_j(0, s)], N_i),$$

$$i = 1, \dots, n, \quad (9.1)$$

$$X_i(0, 0) = 0, \quad i = 2, \dots, n, \quad s = 0, 1, 2, \dots$$

LEMMA 9.1: *Procedure (9.1) is convergent, i.e., the following limits exist:*

$$\lim_{s \rightarrow \infty} X_i(0, s) =: X_i(0), \quad i = 1, \dots, n.$$

THEOREM 9.1: *For the assembly system with n component machines,*

$$\tilde{X}_i(0) = X_i(0) + \mathcal{O}(\mu), \quad i = 1, \dots, n.$$

As before, define the calculated production rate as follows

$$PR = p_0 \prod_{i=1}^n [1 - X_i(0)], \quad (9.2)$$

where $X_i(0)$, $i = 1, \dots, n$, are the steady states of (9.1).

COROLLARY 9.1:

$$\widetilde{PR} = PR + \mathcal{O}(\mu).$$

COROLLARY 9.2: *The calculated production rate, $PR(p_1, \dots, p_n, p_0, N_1, \dots, N_n)$, defined by (9.2) is a monotonically increasing function of all its arguments.*

9.2. Constrained Improvability

9.2.1. WF improvability

THEOREM 9.2: *Assembly system with n component machines is unimprovable with respect to WF if and only if*

$$p_i = p_0 \prod_{j=1}^{i-1} [1 - X_j(0)] \prod_{j=i+1}^n [1 - X_j(0)], \quad i = 1, \dots, n. \quad (9.3)$$

COROLLARY 9.3: *Under conditions (9.3),*

(a).

$$\widetilde{cb}_i = \widetilde{cs}_i + \mathcal{O}(\mu), \quad i = 1, \dots, n;$$

(b).

$$\bar{h}_i = E[\tilde{h}_i] = \frac{N_i}{2} \frac{N_i + 1}{N_i + 1 - p_i} + \mathcal{O}(\mu) \approx \frac{N_i}{2}, \quad i = 1, \dots, n,$$

where $\widetilde{cb}_i$ and $\widetilde{cs}_i$ are the probabilities of communication blockage and starvation of machine i , respectively, and $\bar{h}_i$ is the average occupancy of buffer i .

Therefore,

IMPROVABILITY INDICATOR 9.1: *Assembly system (i)–(vi) with n component machines is unimprovable with respect to WF if the frequency of communication blockage of each component machine is close to the frequency of communication starvation of the assembly machine caused by the lack of the parts produced by this particular component machine; when this situation takes place, each buffer is on the average almost half full.*

Unimprovable distribution of p_i 's is given by

THEOREM 9.3: Assume $\sum_{i=1}^n \frac{1}{N_i} \leq \frac{n+1}{2}$. Then

$$p_i^* = \left(\frac{N_i + 1}{N_i + PR^*} \right) PR^*, i = 1, \dots, n,$$

$$p_0^* = \prod_{i=1}^n \left(\frac{N_i + 1}{N_i + PR^*} \right) PR^*. \quad (9.4)$$

where

$$PR^* = \lim_{s \rightarrow \infty} x(s)$$

and $x(s)$ is defined by the following convergent recursive procedure:

$$x(s+1) = (p^*) \frac{1}{n+1} \prod_{i=1}^n \left(\frac{N_i + x(s)}{N_i + 1} \right)^{\frac{2}{n+1}}. \quad (9.5)$$

Remark 9.1: In comparison with the two component machine case, (9.4) result in a larger imbalance between the component and the assembly machine. This effect was discovered in [12].

9.2.2. WF & WIP improvability

THEOREM 9.4: Assembly system with n component machines is unimprovable with respect to WF and WIP simultaneously if and only if (9.3) takes place and, in addition,

$$X_1(0) = X_2(0) = \dots = X_n(0), \quad (9.6)$$

where, as before, $X_i(0)$, $i = 1, \dots, n$, is the steady state of the recursive procedure (9.1).

COROLLARY 9.4: Under conditions (9.3) and (9.6),

$$\tilde{h}_1 = \tilde{h}_2 + \mathbb{O}(\mu) = \dots = \tilde{h}_n + \mathbb{O}(\mu),$$

where $\tilde{h}_i$, $i = 1, \dots, n$, is the average steady state occupancy of buffer b_i .

Therefore,

IMPROVABILITY INDICATOR 9.2: *Assembly system (i)–(vi) with n component machines is unimprovable with respect to WF and WIP simultaneously if each buffer is on the average close to being half full and the average occupancy of each buffer is almost the same.*

The unimprovable distribution of p_i 's and N_i 's is given by

THEOREM 9.5: *Assume that N^* is a multiple of n . Then*

$$p_1^* = p_2^* = \dots = p_n^* = \left(\frac{N_1^* + 1}{N_1^* + PR^{**}} \right) PR^{**},$$

$$p_0^* = \left(\frac{N_1^* + 1}{N_1^* + PR^{**}} \right)^n PR^{**}, \quad (9.7)$$

$$N_i^* = \frac{N^*}{n}, \quad i = 1, \dots, n,$$

where PR^{**} is calculated according to the recursive procedure (9.5) with N_i 's defined by (9.7).

9.2.3. WIP improvability

The following has been justified numerically:

IMPROVABILITY INDICATOR 9.3: *Assembly system (i)–(vi) with n component machines is unimprovable with respect to WIP if the average occupancies of all buffers are as close to each other as possible, i.e., $\max |\bar{h}_i - \bar{h}_j|$ is minimized over all N_i 's such that $\sum_{i=1}^n N_i = N^*$.*

Remark 9.2: The unimprovable distribution of N_i 's can be reached using an algorithm similar to that described in Remark 6.1.

9.3. Unconstrained Improvability

9.3.1. WF unimprovable case

THEOREM 9.6: *For assembly system (i)–(vi) with n component machines, unimprovable with respect to WF,*

$$p_1 \frac{\partial PR}{\partial p_1} = p_2 \frac{\partial PR}{\partial p_2} = \dots = p_n \frac{\partial PR}{\partial p_n} = p_0 \frac{\partial PR}{\partial p_0}. \quad (9.8)$$

Equalities (9.8), obviously, imply that smallest p_i has the largest $\partial PR / \partial p_i$. Therefore,

IMPROVABILITY INDICATOR 9.4: *To expose the bottleneck machine in a system with n component machines, first ensure that it is unimprovable with respect to WF; then, the machine with the smallest p_i is the bottleneck.*

9.3.2. Improvable case

Consider an assembly shown in Figure 8. As in the two component machines case, the symbol $\widetilde{mb}_i$ under each component machine represents the probabilities of manufacturing blockage and the symbols, $\widetilde{ms}_i$, $i = 1, \dots, n$, under the assembly machine represent the probability of manufacturing starvation due to the lack of parts produced by m_i . The arrows are placed according to the Rule 8.1: If $\widetilde{mb}_i > \widetilde{ms}_i$, the arrow is directed from the upstream to the downstream machine; if $\widetilde{mb}_i < \widetilde{ms}_i$, the direction of the arrow is reversed. For each machine with no arrows emanating from it, the following value of severity is assigned:

$$\widetilde{S} = \widetilde{ms}_i - \widetilde{mb}_i, i = 1, \dots, n.$$

IMPROVABILITY INDICATOR 9.5: *If the assembly system (i)–(vi) with n component machines has a single machine with no arrows emanating from it, then this machine is the bottleneck. If there are multiple machines with no emanating arrows, the primary bottleneck is that with the largest severity.*

10. CONCLUSIONS

An effective continuous improvement process is considered by many as a necessary condition to achieve and maintain a competitive advantage in today's manufacturing market place. Often, however, it is not obvious how to select, design, and implement a continuous improvement process which would be most effective in a given practical situation. Although the general philosophy of manufacturing gurus, such as Diming, Taguchi, Goldratt, is quite helpful, quantitative **engineering** techniques might also be productive in helping to **design** a continuous improvement project, in the same manner as products and processes are designed. The theory developed in this paper provides an instance of such a technique. The authors used it in five different continuous improvement projects carried out during the last 3 years at two automotive component plants and found it to be a useful tool for both improvement of existing production systems and design of new ones. The results of these applications will be reported elsewhere. It is hoped that this approach will prove to be useful for other practitioners and theoreticians alike.

APPENDIX A. PROOFS FOR SECTION 3

Proof of Lemma 3.1: By induction: Since function $Q(x, y, N)$ takes values in $(0, 1)$ and is monotonically increasing in $y, [1]$, for $s = 0$ we have

$$\begin{aligned}
 X_1(0, 1) &= Q(p_1, p_0[1 - X_2(0, 0)], N_1) \\
 &= Q(p_1, p_0, N_1) \\
 &> Q(p_1, p_0[1 - Q(p_2, p_0[1 - X_1(0, 1)], N_2)], N_1) \\
 &= Q(p_1, p_0[1 - X_2(0, 1)], N_1) \\
 &= X_1(0, 2).
 \end{aligned}
 \tag{A.1}$$

Assume that for $s > 0$,

$$X_1(0, s) < X_1(0, s - 1). \tag{A.2}$$

Then, due to the monotonic properties of $Q(x, y, N)$,

$$\begin{aligned} X_2(0, s - 1) &= Q(p_2, p_0[1 - X_1(0, s - 1)], N_2) \\ &< Q(p_2, p_0[1 - X_1(0, s)], N_2) \\ &= X_2(0, s) \end{aligned} \tag{A.3}$$

and

$$\begin{aligned} X_1(0, s + 1) &= Q(p_1, p_0[1 - X_2(0, s)], N_1) \\ &< Q(p_1, p_0[1 - X_2(0, s - 1)], N_1) \\ &= X_1(0, s). \end{aligned} \tag{A.4}$$

Thus, $X_1(0, s)$ is monotonically decreasing in s . Since the sequence $X_1(0, s)$ is monotonic and bounded from above and below (function Q takes values in $(0, 1)$), it is convergent, i.e.,

$$\lim_{s \rightarrow \infty} X_1(0, s) =: X_1(0).$$

Similar arguments are used to prove that $X_2(0, s)$ is convergent and monotonically increasing.

To prove Theorem 3.1, we need the following 5 lemmas:

LEMMA A.1: *Let*

$$\tilde{p}_0^1 := \text{Prob}\{\text{machine } m_0 \text{ produces} \mid \text{buffer } b_1 \text{ has parts}\},$$

$$\tilde{p}_0^2 := \text{Prob}\{\text{machine } m_0 \text{ produces} \mid \text{buffer } b_2 \text{ has parts}\},$$

Then, under Numerical Fact 3.1,

$$\tilde{p}_0^1 = p_0[1 - \tilde{X}_2(0)] + \mathbb{O}(\mu),$$

$$\tilde{p}_0^2 = p_0[1 - \tilde{X}_1(0)] + \mathbb{O}(\mu),$$

where $\tilde{X}_1(0)$ and $\tilde{X}_2(0)$ are the stationary probabilities that buffer b_1 and b_2 are empty.

Proof: Based on the conditional probability formula and Numerical Fact 3.1, we write:

$$\begin{aligned}
 & \text{Prob}\{b_1 \text{ is empty} \mid b_2 \text{ has parts}\} \\
 &= \frac{\sum_{k_2=1}^{N_2} \tilde{X}_{1,2}(0, k_2)}{\sum_{k_2=1}^{N_2} \tilde{X}_2(k_2)} \\
 &= \frac{\sum_{k_2=1}^{N_2} \tilde{X}_1(0) \tilde{X}_2(k_2)}{1 - \tilde{X}_2(0)} + \mathcal{O}(\mu) \\
 &= \frac{\tilde{X}_1(0)[1 - \tilde{X}_2(0)]}{1 - \tilde{X}_2(0)} + \mathcal{O}(\mu) \\
 &= \tilde{X}_1(0) + \mathcal{O}(\mu) \\
 &= \text{Prob}\{b_1 \text{ is empty}\} + \mathcal{O}(\mu). \tag{A.5}
 \end{aligned}$$

Using repeatedly the conditional probability formula, the definition of $\tilde{p}_0^1$, and (A.5), we obtain:

$$\begin{aligned}
 \tilde{p}_0^1 &= \text{Prob}\{m_0 \text{ produces} \mid b_1 \text{ has parts}\} \\
 &= \text{Prob}\{m_0 \text{ is up, } b_1 \text{ has parts, and } b_2 \text{ has parts} \mid b_1 \text{ has parts}\} \\
 &= \frac{\text{Prob}\{m_0 \text{ is up, } b_1 \text{ has parts, and } b_2 \text{ has parts}\}}{\text{Prob}\{b_1 \text{ has parts}\}} \\
 &= \text{Prob}\{m_0 \text{ is up} \mid b_1 \text{ has parts and } b_2 \text{ has parts}\} \cdot \\
 &\quad \frac{\text{Prob}\{b_1 \text{ has parts} \mid b_2 \text{ has parts}\}}{\text{Prob}\{b_1 \text{ has parts}\}} \\
 &\quad \cdot \text{Prob}\{b_2 \text{ has parts}\}
 \end{aligned}$$

$$\begin{aligned}
&= p_0[1 - \tilde{X}_2(0)] \frac{\text{Prob}\{b_1 \text{ has parts} \mid b_2 \text{ has parts}\}}{\text{Prob}\{b_1 \text{ has parts}\}} \\
&= p_0[1 - \tilde{X}_2(0)] \frac{1 - \text{Prob}\{b_1 \text{ is empty} \mid b_2 \text{ has parts}\}}{1 - \text{Prob}\{b_1 \text{ is empty}\}} \\
&= p_0[1 - \tilde{X}_2(0)] + \mathcal{O}(\mu). \tag{A.6}
\end{aligned}$$

This proves the first statement of the lemma. The second is proved analogously. $\blacksquare$

Consider now 2 two-machine-one-buffer lines, L_1 and L_2 , where the first machine of L_1 has the isolation production rate p_1 , the second $\tilde{p}_0^1$, and the buffer capacity is N_1 ; the first machine of L_2 is characterized by p_2 , the second by $\tilde{p}_0^2$, and the buffer capacity is N_2 . Let $\tilde{X}_1(\cdot)$ and $\tilde{X}_2(\cdot)$ be the stationary probability distributions of the buffer occupancy of lines L_1 and L_2 , respectively, and let $\tilde{X}_1(\cdot)$ and $\tilde{X}_2(\cdot)$ be the stationary probability distributions of the occupancy of buffers b_1 and b_2 in the assembly system (i)–(vi). Then, we have

LEMMA A.2: *Under Numerical Fact 3.1, the following is true:*

$$\tilde{X}_i(k_i) = \tilde{X}_i(k_i) + \mathcal{O}(\mu), \quad k_i = 0, \dots, N_i, \quad i = 1, 2.$$

Proof: Since assembly system (i)–(vi) can be described by an ergodic Markov chain with states $\tilde{X}_{1,2}(k_1, k_2)$, in the steady state we write:

$$\begin{aligned}
&\tilde{X}_{1,2}(0, k_2) \\
&= \sum_{k_2} \tilde{X}_{1,2}(0, k_2') \text{Prob}\{m_1 \text{ does not produce} \mid 0, k_2'\} \text{Prob}\{k_2' \rightarrow k_2 \mid 0 \rightarrow 0\} \\
&+ \sum_{k_2} \tilde{X}_{1,2}(1, k_2') \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, k_2'\} \\
&\quad \text{Prob}\{k_2' \rightarrow k_2 \mid 1 \rightarrow 0\}, \tag{A.7}
\end{aligned}$$

where $\text{Prob}\{m_1 \text{ does not produce} \mid k_1, k_2\}$ denotes the conditional probability that machine m_1 does not produce a part during a cycle, given that buffer b_1 contains k_1 and buffer b_2 contains k_2 , and $\text{Prob}\{k'_2 \rightarrow k_2 \mid k'_1 \rightarrow k_1\}$ denotes the conditional probability of the transition from the state where buffer b_2 contains k'_2 parts, given that the number of parts in buffer b_1 change from k'_1 to k_1 . Summation over all k_2 yields

$$\begin{aligned} & \bar{X}_1(0) \\ &= \sum_{k'_2} \tilde{X}_{1,2}(0, k'_2) \text{Prob}\{m_1 \text{ does not produce} \mid 0, k'_2\} \sum_{k_2} \text{Prob}\{k'_2 \rightarrow k_2 \mid 0 \rightarrow 0\} \\ &+ \sum_{k'_2} \tilde{X}_{1,2}(1, k'_2) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, k'_2\} \\ &\quad \sum_{k_2} \text{Prob}\{k'_2 \rightarrow k_2 \mid 1 \rightarrow 0\}, \end{aligned} \tag{A.8}$$

Since $\text{Prob}\{k'_2 \rightarrow k_2 \mid 0 \rightarrow 0\} = 1$,

$$\begin{aligned} \bar{X}_1(0) &= \sum_{k'_2} \tilde{X}_{1,2}(0, k'_2) \text{Prob}\{m_1 \text{ does not produce} \mid 0, k'_2\} \\ &+ \sum_{k'_2} \tilde{X}_{1,2}(1, k'_2) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, k'_2\}. \end{aligned} \tag{A.9}$$

Consider the first term of the right hand side of equation (A.9). Since m_1 is the first machine and b_1 contains zero parts, m_1 is neither starved nor blocked. Therefore,

$$\begin{aligned} & \sum_{k'_2} \tilde{X}_{1,2}(0, k'_2) \text{Prob}\{m_1 \text{ does not produce} \mid 0, k'_2\} \\ &= (1 - p_1) \sum_{k'_2} \tilde{X}_{1,2}(0, k'_2) \\ &= (1 - p_1) \bar{X}_1(0). \end{aligned} \tag{A.10}$$

For the second term of the right hand side of equation (A.9), we write:

$$\begin{aligned}
 & \sum_{k'_2} \tilde{X}_{1,2}(1, k'_2) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, k'_2\} \\
 &= \sum_{k'_2 \geq 1} \tilde{X}_{1,2}(1, k'_2) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, k'_2\} \\
 &+ \tilde{X}_{1,2}(1, 0) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, 0\}.
 \end{aligned} \tag{A.11}$$

When b_1 contains one part and b_2 contains at least one part, m_0 is not starved. If m_0 produces a part, then m_1 is not blocked. Therefore, the conditional probability in the first term on the right hand side of equation (A.11) is equal to $(1 - p_1)p_0$. When b_2 contains zero parts, m_0 is starved, and the conditional probability in the second term on the right hand side of equation (A.11) is equal to 0. Thus,

$$\begin{aligned}
 & \sum_{k'_2} \tilde{X}_{1,2}(1, k'_2) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, k'_2\} \\
 &= (1 - p_1)p_0 \sum_{k'_2 \geq 1} \tilde{X}_{1,2}(1, k'_2).
 \end{aligned} \tag{A.12}$$

Under Numerical Fact 3.1, this can be rewritten as

$$\begin{aligned}
 & \sum_{k'_2} \tilde{X}_{1,2}(1, k'_2) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces} \mid 1, k'_2\} \\
 &= (1 - p_1)p_0[\tilde{X}_1(1) - \tilde{X}_{1,2}(1, 0)] \\
 &= (1 - p_1)p_0[\tilde{X}_1(1) - \tilde{X}_1(1)\tilde{X}_2(0)] + \mathbb{O}(\mu) \\
 &= (1 - p_1)p_0[1 - \tilde{X}_2(0)]\tilde{X}_1(1) + \mathbb{O}(\mu).
 \end{aligned} \tag{A.13}$$

Using Lemma A.1,

$$\begin{aligned}
& \sum_{k'_2} \tilde{X}_{1,2}(1, k'_2) \text{Prob}\{m_1 \text{ does not produce, } m_0 \text{ produces } | 1, k'_2\} \\
&= (1 - p_1) \tilde{p}_0^1 \tilde{X}_1(1) + \mathbb{O}(\mu).
\end{aligned} \tag{A.14}$$

From (A.10) and (A.14), equation (A.9) can be rewritten as

$$\tilde{X}_1(0) = (1 - p_1 + \mathbb{O}(\mu)) \tilde{X}_1(0) + (1 - p_1) \tilde{p}_0^1 \tilde{X}_1(1) + \mathbb{O}(\mu). \tag{A.15}$$

Similar arguments are used to obtain equations for $\tilde{X}_1(k_1)$, $k_1 = 1, \dots, N_1$. As a result, we have the following:

$$\begin{aligned}
\tilde{X}_1(0) &= (1 - p_1 + \mathbb{O}(\mu)) \tilde{X}_1(0) + (1 - p_1) \tilde{p}_0^1 \tilde{X}_1(1), \\
\tilde{X}_1(1) &= p_1 \tilde{X}_1(0) + [p_1 \tilde{p}_0^1 + (1 - p_1)(1 - \tilde{p}_0^1) + \mathbb{O}(\mu)] \tilde{X}_1(1) \\
&\quad + (1 - p_1) \tilde{p}_0^1 \tilde{X}_1(2),
\end{aligned} \tag{A.16}$$

$$\begin{aligned}
\tilde{X}_1(k_1) &= p_1(1 - \tilde{p}_0^1) \tilde{X}_1(k_1 - 1) + [p_1 \tilde{p}_0^1 + (1 - p_1)(1 - \tilde{p}_0^1) + \mathbb{O}(\mu)] \tilde{X}_1(k_1) \\
&\quad + (1 - p_1) \tilde{p}_0^1 \tilde{X}_1(k_1 + 1), \quad k_1 = 2, \dots, N_1 - 1,
\end{aligned}$$

$$\tilde{X}_1(N_1) = p_1(1 - \tilde{p}_0^1) \tilde{X}_1(N_1 - 1) + [1 - \tilde{p}_0^1 + p_1 \tilde{p}_0^1 + \mathbb{O}(\mu)] \tilde{X}_1(N_1).$$

This can be written in matrix form as:

$$\tilde{X}_1 = (A + \Delta A) \tilde{X}_1, \quad \tilde{X}_1 = [\tilde{X}_1(0), \dots, \tilde{X}_1(N_1)]^T \tag{A.17}$$

where

$$A = \begin{bmatrix} 1 - p_1 & (1 - p_1) \tilde{p}_0^1 & & & \\ p_1 & p_1 \tilde{p}_0^1 + (1 - p_1)(1 - \tilde{p}_0^1) & \ddots & & \\ & p_1(1 - \tilde{p}_0^1) & \ddots & \ddots & \\ & & \ddots & p_1 \tilde{p}_0^1 + (1 - p_1)(1 - \tilde{p}_0^1) & (1 - p_1) \tilde{p}_0^1 \\ & & & p_1(1 - \tilde{p}_0^1) & 1 - \tilde{p}_0^1 + p_1 \tilde{p}_0^1 \end{bmatrix} \tag{A.18}$$

and ΔA is a diagonal matrix with diagonal elements all of the order $\mathcal{O}(\mu)$, and therefore $\|\Delta A\| \sim \mathcal{O}(\mu)$.

From Lemma A.5 in [1], the stationary probability $\bar{X}_1(\cdot)$ of line L_1 is described by $\bar{X}_1 = A\bar{X}_1$, where A is defined by (A.18). Since A is the state transition matrix of an ergodic Markov chain, $\lambda = 1$ is an eigenvalue of multiplicity 1. Therefore, using the perturbation theory [16],

$$\tilde{X}_1(k_1) = \bar{X}_1(k_1) + \mathcal{O}(\mu), \quad k_1 = 0, \dots, N_1.$$

Analogously, we can prove that

$$\tilde{X}_2(k_2) = \bar{X}_2(k_2) + \mathcal{O}(\mu), \quad k_2 = 0, \dots, N_2. \quad \blacksquare$$

Lemma A.2 shows that if $\bar{X}_1(\cdot)$ and $\bar{X}_2(\cdot)$ are known, then they can be used to estimate the stationary probability distributions of buffer occupancy $\tilde{X}_1(\cdot)$ and $\tilde{X}_2(\cdot)$. Our next goal is to estimate $\bar{X}_1(0)$ and $\bar{X}_2(0)$. Lemma A.3 shows that this can be accomplished using the recursive procedure (3.3).

LEMMA A.3: *Under Numerical Fact 3.1,*

$$\bar{X}_i(0) = X_i(0) + \mathcal{O}(\mu), \quad i = 1, 2,$$

where $\bar{X}_1(0)$ and $\bar{X}_2(0)$ are, respectively, stationary probabilities that buffers b_1 and b_2 in lines L_1 and L_2 are empty, and $X_1(0)$ and $X_2(0)$ are the steady states of the recursive procedure (3.3).

Proof: Using Lemma A.5 of [1],

$$\bar{X}_1(0) = Q(p_1, \tilde{p}_0^1, N_1). \quad (\text{A.19})$$

Since $\tilde{p}_0^1 = p_0[1 - \bar{X}_2(0)] + \mathcal{O}(\mu)$ from Lemma A.1,

$$\bar{X}_1(0) = Q(p_1, p_0[1 - \bar{X}_2(0)] + \mathcal{O}(\mu), N_1). \quad (\text{A.20})$$

From Lemma A.2 and Lemma B.1 of [6],

$$\begin{aligned}
\bar{X}_1(0) &= Q(p_1, p_0[1 - \bar{X}_2(0)] + \mathcal{O}(\mu), N_1) \\
&= Q(p_1, p_0[1 - \bar{X}_2(0)], N_1) + g_2(p_1, p_0[1 - \bar{X}_2(0)], N_1)\mathcal{O}(\mu) \\
&= Q(p_1, p_0[1 - \bar{X}_2(0)], N_1) + \mathcal{O}(\mu),
\end{aligned} \tag{A.21}$$

where

$$g_2(x, y, N) = \begin{cases} \frac{x - [x + N\frac{x(y-x)}{y(1-y)}]\alpha^N}{y^2(1 - \frac{x}{y}\alpha^N)^2}, & x \neq y, \\ \frac{N(N+1-2x)}{2x(N+1-x)^2}, & x = y, \end{cases}$$

and

$$\alpha = \frac{x(1-y)}{y(1-x)}.$$

Similarly,

$$\bar{X}_2(0) = Q(p_2, p_0[1 - \bar{X}_1(0)], N_2) + \mathcal{O}(\mu). \tag{A.22}$$

As it follows from Lemma 3.1, the steady state equations of recursive procedure (3.3) are given below:

$$X_1(0) = Q(p_1, p_0[1 - X_2(0)], N_1), \tag{A.23}$$

$$X_2(0) = Q(p_2, p_0[1 - X_1(0)], N_2). \tag{A.24}$$

Equations (A.21) and (A.22) show that $\bar{X}_1(0)$ and $\bar{X}_2(0)$ solve equations (A.23) and (A.24) with error $\mathcal{O}(\mu)$, i.e.,

$$\bar{X}_i(0) = X_i(0) + \mathcal{O}(\mu), i = 1, 2.$$

■

According to Lemma 3.1, equations (A.23) and (A.24), i.e.,

$$X_1(0) = Q(p_1, p_0[1 - X_2(0)], N_1),$$

$$X_2(0) = Q(p_2, p_0[1 - X_1(0)], N_2),$$

have a solution $(X_1(0), X_2(0))$. We show below that this solution is, in fact, unique. In order to prove this, introduce 2 two-machine-one-buffer serial production lines, L_i , $i = 1, 2$, where the first machine of L_1 has the production rate in isolation p_1 , the second $p_0[1 - X_2(0)]$, and the buffer capacity N_1 ; analogously, the first machine of L_2 is characterized by p_2 , the second by $p_0[1 - X_1(0)]$, and the buffer by N_2 . Let $PR_2(p_x, p_y, N)$ denote the production rate of a two-machine-one-buffer serial line, i.e., according to [1],

$$PR_2(p_x, p_y, N) = p_x[1 - Q(p_y, p_x, N)] = p_y[1 - Q(p_x, p_y, N)].$$

Then, the following properties hold:

LEMMA A.4: *Let PR_{L_i} , $i = 1, 2$, be the production rate of line L_i . Then*

$$PR_{L_1} = PR_2(p_1, p_0[1 - X_2(0)], N_1),$$

$$PR_{L_2} = PR_2(p_2, p_0[1 - X_1(0)], N_2).$$

In addition,

$$PR = PR_{L_1} = PR_{L_2}.$$

Proof: Using Lemma A.5 of [1], we obtain

$$PR_{L_1} = p_0[1 - X_2(0)][1 - Q(p_1, p_0[1 - X_2(0)], N_1)]$$

$$= p_1[1 - Q(p_0[1 - X_2(0)], p_1, N_1)]$$

$$= PR_2(p_1, p_0[1 - X_2(0)], N_1),$$

$$\begin{aligned}
PR_{L_2} &= p_0[1 - X_1(0)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
&= p_2[1 - Q(p_0[1 - X_1(0)], p_2, N_2)] \\
&= PR_2(p_2, p_0[1 - X_1(0)], N_2).
\end{aligned}$$

Moreover, using (A.23) and (A.24),

$$\begin{aligned}
PR_{L_1} &= p_0[1 - X_2(0)][1 - X_1(0)], \\
PR_{L_2} &= p_0[1 - X_1(0)][1 - X_2(0)].
\end{aligned}$$

Therefore, from (3.5),

$$PR = PR_{L_1} = PR_{L_2}.$$

■

LEMMA A.5: *The equilibrium equations (A.23) and (A.24) of recursive procedure (3.3) have a unique solution.*

Proof: By contradiction: Assume that along with the solution $(X_1(0), X_2(0))$ to equations (A.23) and (A.24), there exists another solution $(\hat{X}_1(0), \hat{X}_2(0))$. Suppose that $\hat{X}_1(0) > X_1(0)$. Then, from Lemma A.4,

$$\begin{aligned}
\widehat{PR}_{L_2} &= PR_2(p_2, p_0[1 - \hat{X}_1(0)], N_2), \\
PR_{L_2} &= PR_2(p_2, p_0[1 - X_1(0)], N_2).
\end{aligned}$$

Since function $PR_2(p_x, p_y, N)$ is monotonically increasing in p_y ,

$$\widehat{PR}_{L_2} < PR_{L_2}.$$

By Lemma A.4,

$$\begin{aligned}
\widehat{PR}_{L_2} &= \widehat{PR}_{L_1} = PR_2(p_1, p_0[1 - \hat{X}_2(0)], N_1) \\
&< PR_{L_2} = PR_{L_1} = PR_2(p_1, p_0[1 - X_2(0)], N_1).
\end{aligned}$$

Again, using the monotonically increasing property of function $PR_2(p_x, p_y, N)$ in p_y ,

$$p_0[1 - \hat{X}_2(0)] < p_0[1 - X_2(0)].$$

Since function $Q(x, y, N)$ is a monotonically increasing function in y ,

$$Q(p_1, p_0[1 - \hat{X}_2(0)], N_1) < Q(p_1, p_0[1 - X_2(0)], N_1),$$

i.e.,

$$\hat{X}_1(0) < X_1(0),$$

which is a contradiction. Hence,

$$\hat{X}_1(0) \leq X_1(0).$$

Assuming that $\hat{X}_1(0) < X_1(0)$, and proceeding analogously, yields $\hat{X}_1(0) \geq X_1(0)$. Therefore, we conclude that

$$\hat{X}_1(0) = X_1(0).$$

Similar arguments are used to prove that $\hat{X}_2(0) = X_2(0)$. Therefore, the solution $(X_1(0), X_2(0))$ is unique. ■

Proof of Theorem 3.1: According to Lemma A.2,

$$\tilde{X}_i(0) = \bar{X}_i(0) + \mathbb{O}(\mu), \quad i = 1, 2.$$

According to Lemmas A.3 and A.5,

$$\bar{X}_i(0) = X_i(0) + \mathbb{O}(\mu), \quad i = 1, 2.$$

Therefore,

$$\tilde{X}_i(0) = X_i(0) + \mathbb{O}(\mu), \quad i = 1, 2.$$

■

Proof of Corollary 3.2: Using Lemma A.2,

$$\tilde{X}_1(k_1) = \tilde{X}_1(k_1) + \mathbb{O}(\mu), k_1 = 0, \dots, N_1. \quad (\text{A.25})$$

By Lemma A.5 of [1] and Lemma A.2,

$$\tilde{X}_1(k_1) = \tilde{X}_1(0) \left(\frac{1}{1 - \tilde{p}_0^1} \right) \tilde{\alpha}_1^{k_1}, k_1 = 1, \dots, N_1, \quad (\text{A.26})$$

where $\tilde{\alpha}_1 = \frac{p_1(1 - \tilde{p}_0^1)}{\tilde{p}_0^1(1 - p_1)}$ and $\tilde{p}_0^1 = p_0[1 - \tilde{X}_2(0)] + \mathbb{O}(\mu)$ (Lemma A.1). Using Lemma A.3 and Theorem 3.1, equation (A.26) can be rewritten as

$$\tilde{X}_1(k_1) = X_1(0) \left(\frac{1}{1 - p_0[1 - X_2(0)]} \right) \alpha_1^{k_1} + \mathbb{O}(\mu), k_1 = 1, \dots, N_1, \quad (\text{A.27})$$

where $\alpha_1 = \frac{p_1(1 - p_0[1 - X_2(0)])}{p_0[1 - X_2(0)](1 - p_1)}$. From (A.25) and (A.27),

$$\tilde{X}_1(k_1) = X_1(0) \left(\frac{1}{1 - p_0[1 - X_2(0)]} \right) \alpha_1^{k_1} + \mathbb{O}(\mu), k_1 = 1, \dots, N_1. \quad (\text{A.28})$$

Similar arguments are used to evaluate $\tilde{X}_2(k_2)$, $k_2 = 1, \dots, N_2$. As a result,

$$\tilde{X}_2(k_2) = X_2(0) \left(\frac{1}{1 - p_0[1 - X_1(0)]} \right) \alpha_2^{k_2} + \mathbb{O}(\mu), k_2 = 1, \dots, N_2, \quad (\text{A.29})$$

where $\alpha_2 = \frac{p_2(1 - p_0[1 - X_1(0)])}{p_0[1 - X_1(0)](1 - p_2)}$. Therefore, from (3.6), we conclude that

$$\tilde{X}_i(k_i) = X_i(k_i) + \mathbb{O}(\mu), k_i = 1, \dots, N_i, i = 1, 2. \quad \blacksquare$$

Proof of Corollary 3.3: Let $PR_2(p_x, p_y, N)$ denote the production rate of a two-machine-one-buffer serial line [1]. Then, we have the following two properties:

- (α). Function $PR_2(p_x, p_y, N)$ is monotonically increasing in p_x, p_y , and N (Lemma A.5 of [1]).
- (β). Function $Q(x, y, N)$, is monotonically decreasing in x and N , and monotonically increasing in y (Lemma A.1 of [1]).

Consider two assembly systems (i)–(vi), the first of which is described by parameters $p_i, i = 0, 1, 2$, and $N_i, i = 1, 2$, and the second by parameters $\hat{p}_i \geq p_i, i = 0, 1, 2$, and $\hat{N}_i \geq N_i, i = 1, 2$. Let $X_i(0)$ and $\hat{X}_i(0), i = 1, 2$, denote the steady state of recursive procedure (3.3) for the first and second assembly systems, respectively. We prove Corollary 3.3 by contradiction.

Assume

$$PR(p_1, p_2, p_0, N_1, N_2) > PR(\hat{p}_1, \hat{p}_2, \hat{p}_0, \hat{N}_1, \hat{N}_2).$$

Thus,

$$\begin{aligned} PR_2(p_1, p_0[1 - X_2(0)], N_1) &= PR(p_1, p_2, p_0, N_1, N_2) \\ &> PR(\hat{p}_1, \hat{p}_2, \hat{p}_0, \hat{N}_1, \hat{N}_2) \\ &= PR_2(\hat{p}_1, \hat{p}_0[1 - \hat{X}_2(0)], \hat{N}_1). \end{aligned}$$

Then, by (α),

$$p_0[1 - X_2(0)] > \hat{p}_0[1 - \hat{X}_2(0)].$$

Hence,

$$\hat{X}_2(0) > X_2(0).$$

Since $\hat{X}_2(0) = Q(\hat{p}_2, \hat{p}_0[1 - \hat{X}_1(0)], \hat{N}_2)$ and $X_2(0) = Q(p_2, p_0[1 - X_1(0)], N_2)$ and (β),

$$\hat{p}_0[1 - \hat{X}_1(0)] > p_0[1 - X_1(0)].$$

Again, using (α) ,

$$PR_2(\hat{p}_2, \hat{p}_0[1 - \hat{X}_1(0)], \hat{N}_2) > PR_2(p_2, p_0[1 - X_1(0)], N_2),$$

i.e.,

$$PR(p_1, p_2, p_0, N_1, N_2) < PR(\hat{p}_1, \hat{p}_2, \hat{p}_0, \hat{N}_1, \hat{N}_2),$$

which contradicts the assumption. Therefore, we conclude that $PR(p_1, p_2, p_0, N_1, N_2)$ is a monotonically increasing function of its arguments. ■

APPENDIX B. PROOFS FOR SECTION 4

To prove Theorem 4.1, Corollary 4.1 and Theorem 4.2, we need Lemmas B.1–B.5. To formulate and prove them, we recall a few results from [1]:

Define function $f_N(x, y)$ as follows:

$$f_N(x, y) = [1 - Q(x, y, N)][1 - Q(y, x, N)],$$

where $Q(x, y, N)$ is given in (3.3). Then

(α) . function $f_N(x, y)$ can be represented as

$$f_N(x, y) = \left[\frac{g(1 - \alpha^N)}{1 - \alpha^N g^2} \right]^2,$$

where

$$g = \sqrt{\frac{x}{y}},$$

$$\alpha = \frac{x(1 - y)}{y(1 - x)},$$

(Lemma B.1 of [1]);

(β). under the constraint $xy = p = \text{const}$, function $f_N(x, y)$, achieves its maximum value if and only if $x = y$. Furthermore,

$$f_N(\sqrt{p}, \sqrt{p}) = \left[\frac{N}{N+1-\sqrt{p}} \right]^2,$$

(Lemma B.2 of [1]).

LEMMA B.1: Let $c_1 = \sqrt{p_1 p_0 [1 - X_2(0)]}$ and $c_2 = \sqrt{p_1 p_0 [1 - X_1(0)]}$. Then

$$c_i \geq PR \left(\frac{N_i + 1}{N_i + PR} \right), i = 1, 2. \quad (\text{B.1})$$

The equality takes place if and only if $p_1 = p_0 [1 - X_2(0)]$ and $p_2 = p_0 [1 - X_1(0)]$.

Proof: From Lemma A.4,

$$\begin{aligned} c_1^2 &= p_1 p_0 [1 - X_2(0)] \\ &= \frac{p_1 [1 - Q(p_0 [1 - X_2(0)], p_1, N_1)] p_0 [1 - X_2(0)] [1 - Q(p_1, p_0 [1 - X_2(0)], N_1)]}{[1 - Q(p_0 [1 - X_2(0)], p_1, N_1)] [1 - Q(p_1, p_0 [1 - X_2(0)], N_1)]} \\ &= \frac{PR^2}{f_{N_1}(p_1, p_0 [1 - X_2(0)])}. \end{aligned} \quad (\text{B.2})$$

By (β) and the definition of c_1 ,

$$f_{N_1}(p_1, p_0 [1 - X_2(0)]) \leq \left[\frac{N_1}{N_1 + 1 - c_1} \right]^2, \quad (\text{B.3})$$

with the equality taking place if and only if $p_1 = p_0 [1 - X_2(0)]$, so

$$c_1^2 \geq \frac{PR^2}{\left[\frac{N_1}{N_1 + 1 - c_1} \right]^2},$$

$$\begin{aligned}
c_1 &\geq \frac{PR(N_1 + 1 - c_1)}{N_1}, \\
c_1 \left(1 + \frac{PR}{N_1}\right) &\geq \frac{PR(N_1 + 1)}{N_1}, \\
c_1 &\geq \frac{PR(N_1 + 1)}{N_1 + PR}.
\end{aligned} \tag{B.4}$$

Analogously,

$$c_2 \geq \frac{PR(N_2 + 1)}{N_2 + PR}. \tag{B.5}$$

■

LEMMA B.2: *The total workforce, p^* , necessary to achieve the production rate value PR , is bounded by*

$$p^* \geq \left(\frac{N_1 + 1}{N_1 + PR}\right)^2 \left(\frac{N_2 + 1}{N_2 + PR}\right)^2 PR^3. \tag{B.6}$$

The equality takes place if and only if

$$p_1 = p_0[1 - X_2(0)],$$

$$p_2 = p_0[1 - X_1(0)].$$

Proof: From (3.5) and Lemma A.4,

$$\begin{aligned}
PR &= p_0[1 - X_1(0)][1 - X_2(0)] \\
&= \frac{p_1 p_0[1 - X_2(0)] p_2 p_0[1 - X_1(0)]}{p_1 p_2 p_0} \\
&= \frac{c_1^2 c_2^2}{p_1 p_2 p_0}.
\end{aligned} \tag{B.7}$$

Thus,

$$p_1 p_2 p_0 = p^* = \frac{c_1^2 c_2^2}{PR}. \quad (\text{B.8})$$

By Lemma B.1,

$$p^* \geq \left(\frac{N_1 + 1}{N_1 + PR} \right)^2 \left(\frac{N_2 + 1}{N_2 + PR} \right)^2 PR^3$$

with the equality taking place if and only if

$$p_1 = p_0[1 - X_2(0)],$$

$$p_2 = p_0[1 - X_1(0)].$$

■

Lemma B.2 gives a lower bound on the workforce necessary to accomplish a desired production rate. The following lemma shows that this bound is achievable.

LEMMA B.3: *The conditions $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$ are achieved if and only if the workforce is distributed as follows:*

$$\begin{aligned} p_1 &= \left(\frac{N_1 + 1}{N_1 + PR} \right) PR, \\ p_2 &= \left(\frac{N_2 + 1}{N_2 + PR} \right) PR, \\ p_0 &= \left(\frac{N_1 + 1}{N_1 + PR} \right) \left(\frac{N_2 + 1}{N_2 + PR} \right) PR. \end{aligned} \quad (\text{B.9})$$

Proof: Suppose $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$. Then, from Lemma A.4,

$$\begin{aligned}
PR &= p_1[1 - Q(p_0[1 - X_2(0)], p_1, N_1)] \\
&= p_1\left(1 - \frac{1 - p_1}{N_1 + 1 - p_1}\right) \\
&= \frac{p_1 N_1}{N_1 + 1 - p_1}.
\end{aligned} \tag{B.10}$$

Solving (B.10) for p_1 , we obtain

$$p_1 = p_0[1 - X_2(0)] = \left(\frac{N_1 + 1}{N_1 + PR}\right) PR. \tag{B.11}$$

Similarly, we have

$$p_2 = p_0[1 - X_1(0)] = \left(\frac{N_2 + 1}{N_2 + PR}\right) PR. \tag{B.12}$$

Using Lemma A.4 and recalling that $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$,

$$\begin{aligned}
PR &= p_0[1 - X_1(0)][1 - X_2(0)] \\
&= p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
&= p_0\left(1 - \frac{1 - p_1}{N_1 + 1 - p_1}\right)\left(1 - \frac{1 - p_2}{N_2 + 1 - p_2}\right) \\
&= p_0\left(\frac{N_1}{N_1 + 1 - p_1}\right)\left(\frac{N_2}{N_2 + 1 - p_2}\right).
\end{aligned} \tag{B.13}$$

Substitute for p_1 using (B.11) and for p_2 using (B.12). Then,

$$\begin{aligned}
 PR &= p_0 \left(\frac{N_1}{N_1 + 1 - \left(\frac{N_1 + 1}{N_1 + PR} \right) PR} \right) \left(\frac{N_2}{N_2 + 1 - \left(\frac{N_2 + 1}{N_2 + PR} \right) PR} \right) \\
 &= p_0 \left(\frac{N_1 + PR}{N_1 + 1} \right) \left(\frac{N_2 + PR}{N_2 + 1} \right). \tag{B.14}
 \end{aligned}$$

Therefore,

$$p_0 = \left(\frac{N_1 + 1}{N_1 + PR} \right) \left(\frac{N_2 + 1}{N_2 + PR} \right) PR.$$

Now suppose that the workforce is distributed as in (B.9). Next we show that this implies that $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$. By Lemma A.5, there is a unique solution to (A.23) and (A.24). From (B.11) and (B.12), we claim that this solution is

$$X_1(0) = 1 - \left(\frac{N_2 + 1}{N_2 + PR} \right) \frac{PR}{p_0} = \frac{1 - PR}{N_1 + 1}, \tag{B.15}$$

$$X_2(0) = 1 - \left(\frac{N_1 + 1}{N_1 + PR} \right) \frac{PR}{p_0} = \frac{1 - PR}{N_2 + 1}.$$

Due to the uniqueness of this solution, we only need to prove that (B.15) is indeed a solution. Consider

$$\begin{aligned}
 Q(p_1, p_0[1 - X_2(0)], N_1) &= Q\left(\frac{N_1 + 1}{N_1 + PR} PR, \frac{N_1 + 1}{N_1 + PR} PR, N_1\right) \\
 &= \frac{1 - \frac{N_1 + 1}{N_1 + PR} PR}{N_1 + 1 - \frac{N_1 + 1}{N_1 + PR} PR}
 \end{aligned}$$

$$\begin{aligned}
&= \frac{1 - PR}{N_1 + 1} \\
&= X_1(0).
\end{aligned} \tag{B.16}$$

Similarly,

$$\begin{aligned}
Q(p_2, p_0[1 - X_1(0)], N_2) &= Q\left(\frac{N_2 + 1}{N_2 + PR} PR, \frac{N_2 + 1}{N_2 + PR} PR, N_2\right) \\
&= \frac{1 - \frac{N_2 + 1}{N_2 + PR} PR}{N_2 + 1 - \frac{N_2 + 1}{N_2 + PR} PR} \\
&= \frac{1 - PR}{N_2 + 1} \\
&= X_2(0).
\end{aligned} \tag{B.17}$$

Therefore, equations (B.16) and (B.17) imply that

$$p_1 = p_0[1 - X_2(0)],$$

$$p_2 = p_0[1 - X_1(0)].$$

■

LEMMA B.4: *The minimum workforce, p_{min}^* , required to achieve production rate PR is given by*

$$p_{min}^* = \left(\frac{N_1 + 1}{N_1 + PR}\right)^2 \left(\frac{N_2 + 1}{N_2 + PR}\right)^2 PR^3.$$

In addition, this production rate is achieved if and only if p^ is distributed among p_1 , p_2 and p_0 so that $p_1 p_2 p_0 = p^*$, $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$.*

Proof: According to Lemma B.2,

$$p_{min}^* \geq \left(\frac{N_1 + 1}{N_1 + PR} \right)^2 \left(\frac{N_2 + 1}{N_2 + PR} \right)^2 PR^3, \quad (\text{B.18})$$

and equality is achieved if and only if $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$. By Lemma B.3, this lower bound is obtained with the workforce distribution as specified in equation (B.9). ■

LEMMA B.5: *The minimum workforce, p_{min}^* , necessary to obtain the production rate PR is a monotonically increasing function of PR .*

Proof: By Lemma B.4, p_{min}^* is given by

$$p_{min}^* = \left(\frac{N_1 + 1}{N_1 + PR} \right)^2 \left(\frac{N_2 + 1}{N_2 + PR} \right)^2 PR^3.$$

Differentiation of p_{min}^* with respect to PR yields

$$\begin{aligned} \frac{\partial p_{min}^*}{\partial PR} &= -2 \left(\frac{N_1 + 1}{N_1 + PR} \right) \frac{(N_1 + 1)}{(N_1 + PR)^2} \left(\frac{N_1 + 1}{N_1 + PR} \right)^2 PR^3 \\ &\quad - \left(\frac{N_1 + 1}{N_1 + PR} \right)^2 2 \left(\frac{N_2 + 1}{N_2 + PR} \right) \frac{(N_2 + 1)}{(N_2 + PR)^2} PR^3 \\ &\quad + \left(\frac{N_1 + 1}{N_1 + PR} \right)^2 \left(\frac{N_1 + 1}{N_1 + PR} \right)^2 3PR^2 \\ &= \frac{(N_1 + 1)^2(N_1 + PR)(N_2 + 1)^2(N_2 + PR)PR^2[3N_1N_2 + PR(N_1 + N_2 - PR)]}{(N_1 + PR)^4(N_2 + PR)^4} > 0. \end{aligned} \quad (\text{B.19})$$

Therefore, p_{min}^* is monotonically increasing in PR . ■

Proof of Theorem 4.1: “Only if”: Suppose the assembly system is unimprovable, but either $p_1 \neq p_0[1 - X_2(0)]$ or $p_2 \neq p_0[1 - X_1(0)]$. Then by Lemma B.4, $p^* > p_{min}^*$. Thus, from Lemma B.5, workforce p^* optimally distributed can achieve a larger production rate, which is a contradiction.

The “if” part follows from Lemma B.4. Indeed, if $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$, the assembly system is unimprovable. ■

Proof of Corollary 4.1: From Theorem 3.1 and Corollary 3.2, the distributions of buffer occupancy $\tilde{X}_1(\cdot)$ and $\tilde{X}_2(\cdot)$ can be approximated with error $\mathbb{O}(\mu)$ by $X_1(\cdot)$ and $X_2(\cdot)$. Hence, under Numerical Fact 3.1,

$$\begin{aligned}
 \widetilde{cb}_1 &= \text{Prob}\{b_1 \text{ is full and } m_0 \text{ fails to take parts from } b_1\} \\
 &= \tilde{X}_1(N_1)(1 - p_0) + \tilde{X}_{1,2}(N_1, 0)p_0 \\
 &= \tilde{X}_1(N_1)(1 - p_0) + \tilde{X}_1(N_1)\tilde{X}_2(0)p_0 + \mathbb{O}(\mu) \\
 &= \tilde{X}_1(N_1)(1 - p_0[1 - \tilde{X}_2(0)]) + \mathbb{O}(\mu) \\
 &= X_1(N_1)(1 - p_0[1 - X_2(0)]) + \mathbb{O}(\mu),
 \end{aligned}$$

$$\begin{aligned}
 \widetilde{cs}_1 &= \text{Prob}\{b_1 \text{ is empty}\} \\
 &= \tilde{X}_1(0) \\
 &= X_1(0) + \mathbb{O}(\mu).
 \end{aligned}$$

Using Lemma A.5 of [1],

$$\widetilde{cb}_1 = Q(p_0[1 - X_2(0)], p_1, N_1) + \mathbb{O}(\mu), \quad (\text{B.20})$$

$$\widetilde{cs}_1 = Q(p_1, p_0[1 - X_2(0)], N_1) + \mathbb{O}(\mu). \quad (\text{B.21})$$

The expressions for $\widetilde{cb}_2$ and $\widetilde{cs}_2$ can be derived analogously:

$$\widetilde{cb}_2 = Q(p_0[1 - X_1(0)], p_2, N_2) + \mathbb{O}(\mu), \quad (\text{B.22})$$

$$\widetilde{cs}_2 = Q(p_2, p_0[1 - X_1(0)], N_2) + \mathbb{O}(\mu). \quad (\text{B.23})$$

Since $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$, from (B.20), (B.21), (B.22) and (B.23), the result of statement (a) follows.

Since $p_1 = p_0[1 - X_2(0)]$ and $p_2 = p_0[1 - X_1(0)]$, from (3.6)

$$X_i(k_i) = \frac{X_i(0)}{1 - p_i}, \quad k_i = 1, \dots, N_i, \quad i = 1, 2, \quad (\text{B.24})$$

where

$$X_i(0) = \frac{1 - p_i}{N_i + 1 - p_i}.$$

Thus,

$$\begin{aligned} \bar{h}_i &= E[\tilde{h}_i] = \sum_{k_i=0}^{N_i} k_i X_i(k_i) + \mathbb{O}(\mu) \\ &= \sum_{k_i=1}^{N_i} k_i \left(\frac{1}{1 - p_i} \right) \left(\frac{1 - p_i}{N_i + 1 - p_i} \right) + \mathbb{O}(\mu) \\ &= \frac{N_i(N_i + 1)}{2(N_i + 1 - p_i)} + \mathbb{O}(\mu), \quad i = 1, 2. \end{aligned} \quad (\text{B.25})$$

This proves statement (b) of the corollary. ■

Proof of Theorem 4.2: It has been shown in Lemma B.3 that (4.1) is satisfied if and only if

$$\begin{aligned} p_1 &= \left(\frac{N_1 + 1}{N_1 + PR^*} \right) PR^*, \\ p_2 &= \left(\frac{N_2 + 1}{N_2 + PR^*} \right) PR^*, \\ p_0 &= \left(\frac{N_1 + 1}{N_1 + PR^*} \right) \left(\frac{N_2 + 1}{N_2 + PR^*} \right) PR^*, \end{aligned}$$

where PR^* is defined by (4.2). Thus, for an assembly system satisfying (4.1),

$$p^* = p_1 p_2 p_0 = (PR^*)^3 \left(\frac{N_1 + 1}{N_1 + PR^*} \right)^2 \left(\frac{N_2 + 1}{N_2 + PR^*} \right)^2.$$

This can be rearranged as

$$PR^* = (p^*)^{\frac{1}{3}} \left(\frac{N_1 + PR^*}{N_1 + 1} \right)^{\frac{2}{3}} \left(\frac{N_2 + PR^*}{N_2 + 1} \right)^{\frac{2}{3}}. \quad (\text{B.26})$$

Define a function $f(\cdot)$ as

$$f(x) = (p^*)^{\frac{1}{3}} \left(\frac{N_1 + x}{N_1 + 1} \right)^{\frac{2}{3}} \left(\frac{N_2 + x}{N_2 + 1} \right)^{\frac{2}{3}}, \quad (\text{B.27})$$

and observe that

$$PR^* = f(PR^*). \quad (\text{B.28})$$

We next prove that $x(s + 1) = f(x(s))$ is a contraction on $[0, 1]$ and, therefore, (B.28) has a unique solution which recursive procedure (4.3) converges to. Calculate

$$\begin{aligned} \frac{df(x)}{dx} &= (p^*)^{\frac{1}{3}} \frac{2}{3} \left(\frac{N_1 + x}{N_1 + 1} \right)^{-\frac{1}{3}} \left(\frac{1}{N_1 + 1} \right) \left(\frac{N_2 + x}{N_2 + 1} \right)^{\frac{2}{3}} \\ &\quad + (p^*)^{\frac{1}{3}} \left(\frac{N_1 + x}{N_1 + 1} \right)^{\frac{2}{3}} \frac{2}{3} \left(\frac{N_2 + x}{N_2 + 1} \right)^{-\frac{1}{3}} \left(\frac{1}{N_2 + 1} \right) \\ &= (p^*)^{\frac{1}{3}} \left(\frac{N_1 + x}{N_1 + 1} \right)^{\frac{2}{3}} \left(\frac{N_2 + x}{N_2 + 1} \right)^{\frac{2}{3}} \frac{2}{3} \left(\frac{1}{N_1 + x} + \frac{1}{N_2 + x} \right). \end{aligned}$$

Since $p^* < 1$ and $\frac{N_i + x}{N_i + 1} \leq 1$ for $0 \leq x \leq 1$, using the assumption $\frac{1}{N_1} + \frac{1}{N_2} \leq \frac{3}{2}$, we have

$$\left| \frac{df(x)}{dx} \right| < 1, 0 \leq x \leq 1.$$

By the Mean Value Theorem, $\exists c \in [x, y]$ such that

$$f(x) - f(y) = \left. \frac{df(x)}{dx} \right|_{x=c} (x - y).$$

Therefore,

$$|f(x) - f(y)| < |x - y|,$$

i.e., $x(s + 1) = f(x(s))$ is a contraction on $[0, 1]$. This completes the proof of Theorem 4.2. ■

APPENDIX C. PROOFS FOR SECTION 5

Proof of Theorem 5.1: Define

$$f(N_1, N_2, x) = (p^*)^{\frac{1}{3}} \left(\frac{N_1 + x}{N_1 + 1} \right)^{\frac{2}{3}} \left(\frac{N_2 + x}{N_2 + 1} \right)^{\frac{2}{3}} \quad (\text{C.1})$$

and

$$f^*(x) = \max_{\substack{N_1, N_2 \\ N_1 + N_2 = N}} f(N_1, N_2, x). \quad (\text{C.2})$$

Using the Lagrange multiplier technique, the values N_1^* and N_2^* which solve (C.2) can be determined as follows: Introduce

$$F(N_1, N_2, \lambda) = f(N_1, N_2, x) + \lambda(N_1 + N_2 - N^*).$$

Then the optimality conditions,

$$\frac{\partial F(N_1, N_2, \lambda)}{\partial N_1} = (p^*)^{\frac{1}{3}} \frac{2}{3} \left(\frac{N_1 + x}{N_1 + 1} \right)^{-\frac{1}{3}} \frac{(1-x)}{(N_1 + 1)^2} \left(\frac{N_2 + x}{N_2 + 1} \right)^{\frac{2}{3}} + \lambda = 0,$$

$$\frac{\partial F(N_1, N_2, \lambda)}{\partial N_2} = (p^*)^{\frac{1}{3}} \left(\frac{N_1 + x}{N_1 + 1} \right)^{\frac{2}{3}} \frac{2}{3} \left(\frac{N_2 + x}{N_2 + 1} \right)^{-\frac{1}{3}} \frac{(1-x)}{(N_2 + 1)^2} + \lambda = 0,$$

are satisfied if and only if $N_1 = N_2$. Therefore, the solution of (C.2) is given by

$$N_i^* = \frac{N^*}{2}, i = 1, 2. \quad (\text{C.3})$$

Consider now recursive procedure (4.3),

$$x(s+1) = f(N_1, N_2, x(s)),$$

and recall that, by Theorem 4.2, $\lim_{s \rightarrow \infty} x(s) = PR(p_1^*, p_2^*, p_0^*, N_1, N_2)$, where $p_i^*, i = 0, 1, 2$, are given by (4.4). Consider now recursive procedure (4.3) defined on the optimal pair (N_1^*, N_2^*) and any other one $(N_1^\#, N_2^\#)$ such that $N_1^\# + N_2^\# = N^*$:

$$x^*(s+1) = f(N_1^*, N_2^*, x^*(s)), \quad (\text{C.4})$$

$$x^\#(s+1) = f(N_1^\#, N_2^\#, x^\#(s)). \quad (\text{C.5})$$

Assume that the initial conditions for (C.4) and (C.5) are the same:

$$x^*(0) = x^\#(0) \in [0, 1].$$

We claim that

(α). $x^*(s) \geq x^\#(s), \forall s > 0$, i.e.,

$$PR(p_1^*, p_2^*, p_0^*, N_1^*, N_2^*) \geq PR(p_1^*, p_2^*, p_0^*, N_1^\#, N_2^\#);$$

(β). $X_1(0) = X_2(0)$.

To prove (α), we use induction. For $s = 1$,

$$x^*(1) \geq x^\#(1),$$

because the sequence N_1^* and N_2^* solves (C.2). Assume that

$$x^*(s) \geq x^\#(s), s > 1.$$

Since

$$\frac{df(x)}{dx} = (p^*)^{\frac{1}{3}} \left(\frac{N_1 + x}{N_1 + 1} \right)^{\frac{2}{3}} \left(\frac{N_2 + x}{N_2 + 1} \right)^{\frac{2}{3}} \frac{2}{3} \left(\frac{1}{N_1 + x} + \frac{1}{N_2 + x} \right) > 0, \quad (\text{C.6})$$

i.e., $f(N_1, N_2, x)$ is monotonically increasing in x , and since the sequence N_1^* and N_2^* solves (C.2),

$$\begin{aligned} x^*(s+1) &= f(N_1^*, N_2^*, x^*(s)) \\ &\geq f(N_1^*, N_2^*, x^\#(s)) \\ &\geq f(N_1^\#, N_2^\#, x^\#(s)) \\ &= x^\#(s+1), \forall s. \end{aligned}$$

For statement (β) , from (C.2) and (B.15),

$$\begin{aligned} X_1(0) &= \frac{1 - PR}{N_1 + 1} = \frac{1 - PR}{\frac{N^*}{2} + 1}, \\ X_2(0) &= \frac{1 - PR}{N_2 + 1} = \frac{1 - PR}{\frac{N^*}{2} + 1}. \end{aligned}$$

■

Proof of Corollary 5.1: By conditions (4.1) and (5.1),

$$p_1 = p_2 = p_0[1 - X_1(0)].$$

Substituting (C.3) into (B.25), we have

$$\bar{h}_i = \frac{\frac{N^*}{2} \left(\frac{N^*}{2} + 1 \right)}{2 \left(\frac{N^*}{2} + 1 - p_1 \right)} + \mathbb{O}(\mu), i = 1, 2.$$

Therefore, under conditions (4.1) and (5.1), equation (5.2) holds. ■

Proof of Theorem 5.2: Similar to that of Theorem 5.1. Equation (5.3) follows directly from (C.2) and (4.4). ■

APPENDIX D. PROOFS FOR SECTION 7

Proof of Theorem 7.1: Consider an assembly system (i)–(iv) with (4.1) taking place. Assume that the workforce distribution is p_i^* , $i = 0, 1, 2$, where p_i^* are defined by (4.4). Modify the workforce distribution to $p_i = gp_i^*$ and $p_j = (1/g)p_j^*$, $i = 0, 1, 2$, and $j = 0, 1, 2$, where $g \neq 0$. Then, we find that the total workforce p^* is preserved and is not depending on g , but that the line is unimprovable when $g = 1$. That is, the production rate achieves its maximum value at $g = 1$. Let $PR = PR(g)$. Consequently, we have

$$\left. \frac{\partial PR(g)}{\partial g} \right|_{g=1} = 0. \quad (D.1)$$

By the chain rule,

$$\begin{aligned} \left. \frac{\partial PR(g)}{\partial g} \right|_{g=1} &= \left(\frac{\partial PR(g)}{\partial (gp_i^*)} \frac{\partial (gp_i^*)}{\partial g} + \frac{\partial PR(g)}{\partial \left(\frac{p_j^*}{g} \right)} \frac{\partial \left(\frac{p_j^*}{g} \right)}{\partial g} \right) \bigg|_{g=1} \\ &= \left(p_i^* \frac{\partial PR(g)}{\partial p_i} - p_j^* \left(\frac{1}{g} \right)^2 \frac{\partial PR(g)}{\partial p_j} \right) \bigg|_{g=1}, i = 0, 1, 2, j = 0, 1, 2. \end{aligned} \quad (D.2)$$

From (D.1),

$$p_i^* \frac{\partial PR(g)}{\partial p_i} \Big|_{g=1} - p_j^* \frac{\partial PR(g)}{\partial p_j} \Big|_{g=1} = 0.$$

Since i and j are chosen arbitrarily, we therefore conclude that

$$p_i^* \frac{\partial PR(g)}{\partial p_i} \Big|_{g=1} = p_j^* \frac{\partial PR(g)}{\partial p_j} \Big|_{g=1}, \quad i = 0, 1, 2, j = 0, 1, 2.$$

■

APPENDIX E. PROOFS FOR SECTION 8

To prove Theorem 8.1, we need three auxiliary facts:

LEMMA E.1: *The following is true:*

(E.1)

$$\begin{aligned} \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} &= \frac{p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_1(p_1, p_0[1 - X_2(0)], N_1)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)}, \\ \frac{\partial p_0[1 - X_1(0)]}{\partial p_2} &= \frac{p_0^2 g_2(p_1, p_0[1 - X_2(0)], N_1) g_1(p_2, p_0[1 - X_1(0)], N_2)}{1 - p_0^2 g_2(p_1, p_0[1 - X_2(0)], N_1) g_2(p_2, p_0[1 - X_1(0)], N_2)}, \\ \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} &= \frac{1 - Q(p_2, p_0[1 - X_1(0)], N_2)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)} \\ &\quad - \frac{[1 - Q(p_1, p_0[1 - X_2(0)], N_1)] p_0 g_2(p_2, p_0[1 - X_1(0)], N_2)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)}, \\ \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} &= \frac{1 - Q(p_1, p_0[1 - X_2(0)], N_1)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)} \\ &\quad - \frac{[1 - Q(p_2, p_0[1 - X_1(0)], N_2)] p_0 g_2(p_1, p_0[1 - X_2(0)], N_1)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)}, \end{aligned}$$

where $X_1(0)$ and $X_2(0)$ are the steady states of recursive procedure (3.3), $Q(x, y, N)$ is defined in (3.3) and

$$g_1(x, y, N) = \frac{\partial Q(x, y, N)}{\partial x} = \begin{cases} \frac{-1 + \alpha^N + N \frac{y-x}{y(1-x)} \alpha^N}{y(1 - \frac{x}{y} \alpha^N)^2}, & x \neq y, \\ \frac{-N(N+1)}{2x(N+1-x)^2}, & x = y, \end{cases} \quad (\text{E.2})$$

$$g_2(x, y, N) = \frac{\partial Q(x, y, N)}{\partial y} = \begin{cases} \frac{x - [x + N \frac{x(y-x)}{y(1-y)}] \alpha^N}{y^2(1 - \frac{x}{y} \alpha^N)^2}, & x \neq y, \\ \frac{N(N+1-2x)}{2x(N+1-x)^2}, & x = y, \end{cases}$$

where $\alpha = x(1-y) / y(1-x)$.

Proof: The expression for $\partial p_0[1 - X_2(0)] / \partial p_1$ is derived as follows:
From (A.24),

$$\begin{aligned} \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} &= \frac{\partial p_0[1 - Q(p_2, p_0[1 - X_1(0)], N_2)]}{\partial p_1} \\ &= -p_0 \frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_1} \\ &= -p_0 \left[\frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_2} \frac{\partial p_2}{\partial p_1} \right] \\ &\quad - p_0 \left[\frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_0[1 - X_1(0)]} \frac{\partial p_0[1 - X_1(0)]}{\partial p_1} \right]. \end{aligned}$$

Since $\partial p_2 / \partial p_1 = 0$, by Lemma B.1 of [6],

$$\frac{\partial p_0[1 - X_2(0)]}{\partial p_1} = -p_0 g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_1},$$

where $g_2(x, y, N)$ is given by (E.2). From (A.23),

$$\begin{aligned}
 & \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} \\
 &= -p_0 g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)]}{\partial p_1} \\
 &= -p_0 g_2(p_2, p_0[1 - X_1(0)], N_2) \left[-p_0 \frac{dQ(p_1, p_0[1 - X_2(0)], N_1)}{dp_1} \right] \\
 &= -p_0 g_2(p_2, p_0[1 - X_1(0)], N_2) \\
 & \left[-p_0 \frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_1} \frac{\partial p_1}{\partial p_1} - p_0 \frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_0[1 - X_2(0)]} \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} \right] \\
 &= p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_1(p_1, p_0[1 - X_2(0)], N_1) \\
 &+ p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_1}. \tag{E.3}
 \end{aligned}$$

Therefore, solving (E.3) for $\partial p_0[1 - X_2(0)]/\partial p_1$,

$$\frac{\partial p_0[1 - X_2(0)]}{\partial p_1} = \frac{p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_1(p_1, p_0[1 - X_2(0)], N_1)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)}.$$

The expression of $\partial p_0[1 - X_1(0)]/\partial p_2$ is obtained analogously.

The expressions for $\partial p_0[1 - X_2(0)]/\partial p_0$ and $\partial p_0[1 - X_1(0)]/\partial p_0$ are derived as follows:

$$\begin{aligned}
 \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} &= \frac{\partial p_0[1 - Q(p_2, p_0[1 - X_1(0)], N_2)]}{\partial p_0} \\
 &= 1 - Q(p_2, p_0[1 - X_1(0)], N_2) \\
 &\quad - p_0 \frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_0}
 \end{aligned}$$

$$\begin{aligned}
&= 1 - Q(p_2, p_0[1 - X_1(0)], N_2) \\
&\quad - p_0 \left[\frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_2} \frac{\partial p_2}{\partial p_0} \right. \\
&\quad \left. + \frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_0[1 - X_1(0)]} \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} \right], \\
\frac{\partial p_0[1 - X_1(0)]}{\partial p_0} &= \frac{\partial p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)]}{\partial p_0} \\
&= 1 - Q(p_1, p_0[1 - X_2(0)], N_1) \\
&\quad - p_0 \frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_0} \\
&= 1 - Q(p_1, p_0[1 - X_2(0)], N_1) \\
&\quad - p_0 \left[\frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_1} \frac{\partial p_1}{\partial p_0} \right. \\
&\quad \left. + \frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_0[1 - X_2(0)]} \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \right].
\end{aligned}$$

Since $\partial p_2 / \partial p_0 = 0$ and $\partial p_1 / \partial p_0 = 0$, using Lemma B.1 of [1],

$$\begin{aligned}
\frac{\partial p_0[1 - X_2(0)]}{\partial p_0} &= 1 - Q(p_2, p_0[1 - X_1(0)], N_2) \\
&\quad - p_0 g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_0}, \tag{E.4}
\end{aligned}$$

$$\begin{aligned}
\frac{\partial p_0[1 - X_1(0)]}{\partial p_0} &= 1 - Q(p_1, p_0[1 - X_2(0)], N_1) \\
&\quad - p_0 g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_0}, \tag{E.5}
\end{aligned}$$

where $g_2(x, y, N)$ is defined by (E.2). Equations (E.4) and (E.5) can be re-written in the matrix form as follows:

$$\begin{bmatrix} 1 & p_0 g_2(p_2, p_0[1 - X_1(0)], N_2) \\ p_0 g_2(p_1, p_0[1 - X_2(0)], N_1) & 1 \end{bmatrix} \begin{bmatrix} \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\ \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} \end{bmatrix} = \begin{bmatrix} 1 - Q(p_2, p_0[1 - X_1(0)], N_2) \\ 1 - Q(p_1, p_0[1 - X_2(0)], N_1) \end{bmatrix}. \quad (\text{E.6})$$

Solving (E.6) for $\partial p_0[1 - X_2(0)]/\partial p_0$ and $\partial p_0[1 - X_1(0)]/\partial p_0$, we obtain

$$\begin{aligned} \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} &= \frac{1 - Q(p_2, p_0[1 - X_1(0)], N_2)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)} \\ &\quad - \frac{[1 - Q(p_1, p_0[1 - X_2(0)], N_1)] p_0 g_2(p_2, p_0[1 - X_1(0)], N_2)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)}, \\ \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} &= \frac{1 - Q(p_1, p_0[1 - X_2(0)], N_1)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)} \\ &\quad - \frac{[1 - Q(p_2, p_0[1 - X_1(0)], N_2)] p_0 g_2(p_1, p_0[1 - X_2(0)], N_1)}{1 - p_0^2 g_2(p_2, p_0[1 - X_1(0)], N_2) g_2(p_1, p_0[1 - X_2(0)], N_1)}. \end{aligned}$$

■

LEMMA E.2: For assembly system (i)–(vi),

$$\frac{\partial PR}{\partial p_1} = 1 - Q(p_0[1 - X_2(0)], p_1, N_1) \quad (\text{E.7})$$

$$-p_1[g_1(p_0[1 - X_2(0)], p_1, N_1)] \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} + g_2(p_0[1 - X_2(0)], p_1, N_1),$$

$$\begin{aligned}
\frac{\partial PR}{\partial p_2} &= 1 - Q(p_0[1 - X_1(0)], p_2, N_2) \\
&\quad - p_2[g_1(p_0[1 - X_1(0)], p_2, N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_2} + g_2(p_0[1 - X_1(0)], p_2, N_2)], \\
\frac{\partial PR}{\partial p_0} &= [1 - Q(p_1, p_0[1 - X_2(0)], N_1)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
&\quad - p_0[1 - Q(p_2, p_0[1 - X_1(0)], N_2)]g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\
&\quad - p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)]g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_0},
\end{aligned}$$

where $\partial p_0[1 - X_2(0)]/\partial p_1$, $\partial p_0[1 - X_1(0)]/\partial p_2$, $\partial p_0[1 - X_2(0)]/\partial p_0$, $\partial p_0[1 - X_1(0)]/\partial p_0$, $g_1(x, y, N)$ and $g_2(x, y, N)$ are given by (E.1) and (E.2), respectively.

Proof: By Lemma A. 4,

$$\begin{aligned}
\frac{\partial PR}{\partial p_1} &= \frac{\partial p_1[1 - Q(p_0[1 - X_2(0)], p_1, N_1)]}{\partial p_1} \\
&= 1 - Q(p_0[1 - X_2(0)], p_1, N_1) - p_1 \frac{dQ(p_0[1 - X_2(0)], p_1, N_1)}{dp_1} \\
&= 1 - Q(p_0[1 - X_2(0)], p_1, N_1) \\
&\quad - p_1 \left[\frac{\partial Q(p_0[1 - X_2(0)], p_1, N_1)}{\partial p_0[1 - X_2(0)]} \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} \right. \\
&\quad \left. + \frac{\partial Q(p_0[1 - X_2(0)], p_1, N_1)}{\partial p_1} \right],
\end{aligned}$$

$$\begin{aligned}
\frac{\partial PR}{\partial p_2} &= \frac{\partial p_2[1 - Q(p_0[1 - X_1(0)], p_2, N_2)]}{\partial p_2} \\
&= 1 - Q(p_0[1 - X_1(0)], p_2, N_2) - p_2 \frac{dQ(p_0[1 - X_1(0)], p_2, N_2)}{dp_2} \\
&= 1 - Q(p_0[1 - X_1(0)], p_2, N_2) \\
&\quad - p_2 \left[\frac{\partial Q(p_0[1 - X_1(0)], p_2, N_2)}{\partial p_0[1 - X_1(0)]} \frac{\partial p_0[1 - X_1(0)]}{\partial p_2} \right. \\
&\quad \left. + \frac{\partial Q(p_0[1 - X_1(0)], p_2, N_2)}{\partial p_2} \right], \tag{E.8}
\end{aligned}$$

$$\begin{aligned}
\frac{\partial PR}{\partial p_0} &= \frac{\partial p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)]}{\partial p_0} \\
&= [1 - Q(p_1, p_0[1 - X_2(0)], N_1)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
&\quad - p_0[1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_0} \\
&\quad - p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)] \frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_0} \\
&= [1 - Q(p_1, p_0[1 - X_2(0)], N_1)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
&\quad - p_0[1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
&\quad \left[\frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_1} \frac{\partial p_1}{\partial p_0} \right. \\
&\quad \left. + \frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_0[1 - X_2(0)]} \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \right] \\
&\quad - p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)] \\
&\quad \left[\frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_2} \frac{\partial p_2}{\partial p_0} \right]
\end{aligned}$$

$$\begin{aligned}
& + \frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_0[1 - X_1(0)]} \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} \Big] \\
& = [1 - Q(p_1, p_0[1 - X_2(0)], N_1)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
& \quad - p_0[1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
& \quad \frac{\partial Q(p_1, p_0[1 - X_2(0)], N_1)}{\partial p_0[1 - X_2(0)]} \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\
& \quad - p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)] \\
& \quad \frac{\partial Q(p_2, p_0[1 - X_1(0)], N_2)}{\partial p_0[1 - X_1(0)]} \frac{\partial p_0[1 - X_1(0)]}{\partial p_0}.
\end{aligned}$$

Using the expressions for $\partial Q(x, y, N)/\partial x$ and $\partial Q(x, y, N)/\partial y$ from (E.2), and the expressions for $\partial p_0[1 - X_2(0)]/\partial p_1$, $\partial p_0[1 - X_1(0)]/\partial p_2$, $\partial p_0[1 - X_2(0)]/\partial p_0$, and $\partial p_0[1 - X_1(0)]/\partial p_0$ from (E.1), (E.8) is reduced to (E.7). ■

LEMMA E.3: Under Hypothesis 8.1, the following hold:

(a) if $mb_j > ms_j$, then

$$g_2(p_j, p_0[1 - X_{3-j}(0)], N_j) \frac{\partial p_0[1 - X_{3-j}(0)]}{\partial p_0} \sim \mathcal{O}(\epsilon), \quad j = 1, 2; \quad (\text{E.9})$$

(b) if $mb_j < ms_j$, then

$$\begin{aligned}
& g_1(p_0[1 - X_{3-j}(0)], p_j, N_j) \frac{\partial p_0[1 - X_{3-j}(0)]}{\partial p_j} + g_2(p_0[1 - X_{3-j}(0)], p_j, N_j) \sim \mathcal{O}(\epsilon), \\
& j = 1, 2, \quad (\text{E.10})
\end{aligned}$$

where $\epsilon = \max_{j,s}(\epsilon_{j1}, \epsilon_{s2})$ and $g_1(x, y, N)$, $g_2(x, y, N)$, $\partial p_0[1 - X_{3-j}(0)]/\partial p_0$, and $\partial p_0[1 - X_{3-j}(0)]/\partial p_j$, $j = 1, 2$, are given by (E.2) and (E.1), respectively.

Proof: Statement (a) is proved as follows: Under Hypothesis 8.1,

$$\begin{aligned}\epsilon_{j1} &= Q(p_j, p_0[1 - X_{3-j}(0)], N_j) = \frac{(1 - p_j)(1 - \alpha)}{1 - \frac{p_j}{p_0[1 - X_{3-j}(0)]} \alpha^{N_j}} \\ &= \frac{\frac{p_0[1 - X_{3-j}(0)] - p_j}{p_0[1 - X_{3-j}(0)]}}{1 - \frac{p_j}{p_0[1 - X_{3-j}(0)]} \alpha^{N_j}} << 1, j = 1, 2,\end{aligned}$$

where

$$\alpha = \frac{p_j(1 - p_0[1 - X_{3-j}(0)])}{p_0[1 - X_{3-j}(0)](1 - p_j)}.$$

Hence,

$$1 - \frac{p_j}{p_0[1 - X_{3-j}(0)]} \alpha^{N_j} = \frac{p_0[1 - X_{3-j}(0)] - p_j}{\epsilon_{j1} p_0[1 - X_{3-j}(0)]}, j = 1, 2. \quad (\text{E.11})$$

Using (E.2) and (E.11), we write:

$$\begin{aligned}g_2(p_j, p_0[1 - X_{3-j}(0)], N_j) &= \\ &= \frac{\epsilon_{j1}^2 \{p_j - [p_j + \frac{N_j(p_0[1 - X_{3-j}(0)] - p_j)}{p_0[1 - X_{3-j}(0)](1 - p_0[1 - X_{3-j}(0)])}] (1 - \frac{p_0[1 - X_{3-j}(0)] - p_j}{\epsilon_{j1} p_0[1 - X_{3-j}(0)]} \frac{p_0[1 - X_{3-j}(0)]}{p_j})\}}{(p_0[1 - X_{3-j}(0)] - p_j)^2} \sim \mathbb{O}(\epsilon).\end{aligned} \quad (\text{E.12})$$

By Lemma E.1 and (E.12),

$$\begin{aligned}&\frac{\partial p_0[1 - X_{3-j}(0)]}{\partial p_0} \\ &\approx \frac{1 - Q(p_{3-j}, p_0[1 - X_j(0)], N_{3-j}) - (1 - \epsilon_{j1})p_0 g_2(p_{3-j}, p_0[1 - X_j(0)], N_{3-j})}{1 - p_0^2 g_2(p_{3-j}, p_0[1 - X_j(0)], N_{3-j}) \mathbb{O}(\epsilon)}\end{aligned}$$

Neglecting the $\mathbb{O}(\epsilon)$ terms, we have

$$\begin{aligned} \frac{\partial p_0[1 - X_{3-j}(0)]}{\partial p_0} &\approx 1 - Q(p_{3-j}, p_0[1 - X_j(0)], N_{3-j}) \\ &\quad - p_0 g_2(p_{3-j}, p_0[1 - X_j(0)], N_{3-j}). \end{aligned} \quad (\text{E.13})$$

Therefore, substituting (E.13) into the left hand side of (E.9) and using (E.12), we conclude that

$$g_2(p_j, p_0[1 - X_{3-j}(0)], N_j) \frac{\partial p_0[1 - X_{3-j}(0)]}{\partial p_0} \sim \mathcal{O}(\epsilon), j = 1, 2.$$

Statement (b) is proved similarly. ■

Proof of Theorem 8.1: Under the assumption that system (i)–(vi) has a unique machine, m_i , $i \in \{0, 1, 2\}$, with no arrows emanating from it, the following three cases are possible:

$$(\alpha) \quad mb_1 < ms_1 \text{ and } ms_2 < mb_2;$$

$$(\beta) \quad mb_1 > ms_1 \text{ and } ms_2 < mb_2;$$

$$(\gamma) \quad mb_1 > ms_1 \text{ and } ms_2 > mb_2.$$

Consider first case (α) . Under Hypothesis 8.1, using Lemmas E.2 and E.3, for the first component machine,

$$\begin{aligned} \frac{\partial PR}{\partial p_1} &= 1 - Q(p_0[1 - X_2(0)], p_1, N_1) \\ &\quad - p_1[g_1(p_0[1 - X_2(0)], p_1, N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} \\ &\quad + g_2(p_0[1 - X_2(0)], p_1, N_1)] \\ &= 1 - \epsilon_{12} - p_1[g_1(p_0[1 - X_2(0)], p_1, N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} \end{aligned}$$

$$\begin{aligned}
& + g_2(p_0[1 - X_2(0)], p_1, N_1)] \\
& = 1 - \alpha_1,
\end{aligned} \tag{E.14}$$

where

$$\begin{aligned}
\alpha_1 = & \epsilon_{12} + p_1[g_1(p_0[1 - X_2(0)], p_1, N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} \\
& + g_2(p_0[1 - X_2(0)], p_1, N_1)] \sim \mathbb{O}(\epsilon).
\end{aligned}$$

Analogously, for the second component machine,

$$\begin{aligned}
\frac{\partial PR}{\partial p_2} = & 1 - Q(p_0[1 - X_1(0)], p_2, N_2) \\
& - p_2[g_1(p_0[1 - X_1(0)], p_2, N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_2} + g_2(p_0[1 - X_1(0)], p_2, N_2)] \\
& = 1 - \alpha_2,
\end{aligned} \tag{E.15}$$

where

$$\begin{aligned}
\alpha_2 = & Q(p_0[1 - X_1(0)], p_2, N_2) \\
& + p_2[g_1(p_0[1 - X_1(0)], p_2, N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_2} + g_2(p_0[1 - X_1(0)], p_2, N_2)] \\
& \sim \mathbb{O}(1).
\end{aligned}$$

Finally, for the assembly machine,

$$\begin{aligned}
\frac{\partial PR}{\partial p_0} = & [1 - Q(p_1, p_0[1 - X_2(0)], N_1)][1 - Q(p_2, p_0[1 - X_1(0)], N_2)] \\
& - p_0[1 - Q(p_2, p_0[1 - X_1(0)], N_2)]g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\
& - p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)]
\end{aligned}$$

$$\begin{aligned}
& g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} \\
&= [1 - Q(p_1, p_0[1 - X_2(0)], N_1)](1 - \epsilon_{21}) \\
&\quad - p_0(1 - \epsilon_{21})g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\
&\quad - p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)] \\
& g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} \\
&= 1 - \alpha_0,
\end{aligned}$$

where

$$\begin{aligned}
\alpha_0 &= Q(p_1, p_0[1 - X_2(0)], N_1)(1 - \epsilon_{21}) \\
&\quad + p_0(1 - \epsilon_{21})g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\
&\quad + p_0[1 - Q(p_1, p_0[1 - X_2(0)], N_1)] \\
& g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} \sim \mathbb{O}(1).
\end{aligned}$$

Therefore,

$$\frac{\partial PR}{\partial p_1} > \frac{\partial PR}{\partial p_2} \text{ and } \frac{\partial PR}{\partial p_1} > \frac{\partial PR}{\partial p_0},$$

i.e., the first component machine is the bottleneck.

Consider now case (β). Using Hypothesis 8.1 and Lemmas E.2 and E.3, $\partial PR/\partial p_1$ and $\partial PR/\partial p_0$ are estimated as follows:

$$\begin{aligned}
\frac{\partial PR}{\partial p_1} &= 1 - Q(p_0[1 - X_2(0)], p_1, N_1) \\
&\quad - p_1[g_1(p_0[1 - X_2(0)], p_1, N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} + g_2(p_0[1 - X_2(0)], p_1, N_1)] \\
&= 1 - \alpha_1,
\end{aligned}$$

where

$$\begin{aligned}
\alpha_1 &= Q(p_0[1 - X_2(0)], p_1, N_1) \\
&\quad + p_1[g_1(p_0[1 - X_2(0)], p_1, N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_1} \\
&\quad + g_2(p_0[1 - X_2(0)], p_1, N_1)] \sim \mathbb{O}(1).
\end{aligned}$$

and

$$\begin{aligned}
\frac{\partial PR}{\partial p_0} &= (1 - \epsilon_{11})(1 - \epsilon_{21}) \\
&\quad - p_0(1 - \epsilon_{21})g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\
&\quad - p_0(1 - \epsilon_{11})g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_0}, \\
&= 1 - \alpha_0,
\end{aligned}$$

where

$$\begin{aligned}
\alpha_0 &= \epsilon_{11} + \epsilon_{21}(1 - \epsilon_{11}) \\
&\quad + p_0(1 - \epsilon_{21})g_2(p_1, p_0[1 - X_2(0)], N_1) \frac{\partial p_0[1 - X_2(0)]}{\partial p_0} \\
&\quad + p_0(1 - \epsilon_{11})g_2(p_2, p_0[1 - X_1(0)], N_2) \frac{\partial p_0[1 - X_1(0)]}{\partial p_0} \sim \mathbb{O}(\epsilon).
\end{aligned}$$

The expression for $\partial PR/\partial p_2$ remains the same as in case (α), i.e., (E.15). Therefore,

$$\frac{\partial PR}{\partial p_0} > \frac{\partial PR}{\partial p_1} \text{ and } \frac{\partial PR}{\partial p_0} > \frac{\partial PR}{\partial p_2},$$

i.e., the assembly machine is the bottleneck.

Case (γ) is similar to case (α) and is proved analogously. ■
