We propose an elaborate geometry approach to explain the group law on twisted Edwards curves which are seen as the intersection of quadric surfaces in place. Using the geometric interpretation of the group law, we obtain the Miller function for Tate pairing computation on twisted Edwards curves. Then we present the explicit formulae for pairing computation on twisted Edwards curves. Our formulae for the doubling step are a little faster than that proposed by Arène et al. Finally, to improve the efficiency of pairing computation, we present twists of degrees 4 and 6 on twisted Edwards curves.

1. Introduction

Pairing-based cryptography has been one of the most active areas in elliptic curve cryptography since 2000. Some details on this subject can be found in [1, 2]. How to compute pairings efficiently is a bottleneck for implementing pairing-based cryptography. The most efficient method of computing pairings is Miller's algorithm [3]. Consequently, various improvements were presented in [4–8]. One way to improve the efficiency is to find other models of elliptic curves which can provide more efficient algorithms for pairing computation. Edwards curves were one of the popular models. Edwards curve was discovered by Edwards [9] and was applied in cryptography by Bernstein and Lange [10]. Then twisted Edwards curves which are the generalization of Edwards curves were introduced by Bernstein et al. in [11]. Bernstein and Lange also pointed out several advantages of applying the Edwards curves to cryptography. Pairing computation over Edwards curves was first considered in [12, 13]. In 2009, Arène et al. [4] gave the geometric interpretation of the group law and presented explicit formulae for computing the Tate pairing on twisted Edwards curves. Their formulae are faster than all previously proposed formulas for pairings computation on twisted Edwards curves. Their formulae are even competitive with all published formulae for pairing computation on Weierstrass curves. In particular, if a pairing-friendly curve

used in a pairing-based protocol is isomorphic or isogenous to an Edwards curve, all the scalar multiplication appearing in the protocol can be computed efficiently [14].

Any elliptic curve defined over a field K with characteristic different from 2 is birationally equivalent to an Edwards curve over some extension of K , that is, a curve given by $x^2 + y^2 = 1 + dx^2y^2$ with $d \notin \{0, 1\}$. In fact, the twisted Edwards curves can be seen as the intersection of two quadratic surfaces in space. That is to say, the twisted Edwards curves can be given by $SW_{a,d} : aX^2 + Y^2 - Z^2 - dW^2 = 0$, $XY - ZW = 0$. For general elliptic curves given by intersection of two quadratic surfaces, the geometric interpretation of group law had been discussed by Merriman et al. in [15]. In this paper, we proposed a more detailed geometry approach to explain the group law for the case of twisted Edwards curves which are seen as the intersection of two quadratic surfaces. Using the geometric interpretation of the group law, we obtain the Miller function of Tate pairing computation on twisted Edwards curves. Then we present the explicit formulae for pairing computation on twisted Edwards curves. The doubling step of our formulae is a little faster than that in [4]. Finally, to reduce the cost of evaluating the Miller function on twisted Edwards curve, we employ quadratic, quartic, or sextic twists to the formulae of the Tate pairing computation. The high twists had been sufficiently studied by Costello et al. [16] on Weierstrass curves. As the result

given by [17], one elliptic curve and its quartic/sextic twist can not have a rational twisted Edwards model at the same time, so we turn to Weierstrass curves for the high-degree twists of twisted Edwards curves. These twists enable us to reduce the cost of substituting to a half and a third, respectively, in $j = 1728$ case and $j = 0$ case.

The remainder of the paper is organized as follows. In Section 2, we provide some backgrounds and notations used in this paper. In Section 3, we give a geometry approach to explain the group law on twisted Edwards curves. In Section 4, we present pairing computation on twisted Edwards curves. In Section 5, we employ quartic and sextic twists to the formulae of the Tate pairing computation. In Section 6, we conclude our paper.

2. Preliminaries

2.1. Tate Pairing. Let $p > 3$ be a prime, and let $\mathbb{F}_q$ be a finite field with $q = p^n$. E is an elliptic curve defined over $\mathbb{F}_q$ with neutral element denoted by O . r is a prime such that $r \nmid \#E(\mathbb{F}_q)$. Let $k > 1$ denote the embedding degree with respect to r ; that is, k is the smallest positive integer such that $r \mid q^k - 1$. For any point $P \in E(\mathbb{F}_q)[r]$, there exists a rational function f_P defined over $\mathbb{F}_q$ such that $\text{div}(f_P) = r(P) - r(O)$, which is unique up to a nonzero scalar multiple. The group of r th roots of unity in $\mathbb{F}_{q^k}$ is denoted by μ_r . The reduced Tate pairing is then defined as follows:

$$T_r : E(\mathbb{F}_q)[r] \times E(\mathbb{F}_{q^k}) \longrightarrow \mu_r : (P, Q) \longmapsto f_P(Q)^{(q^k-1)/r}. \quad (1)$$

The rational function f_P can be computed in polynomial time by using Miller's algorithm [3]. Let $r = (r_{l-1}, \dots, r_1, r_0)_2$ be the binary representation of r , where $r_{l-1} = 1$. Let $g_{P_1, P_2} \in \mathbb{F}_q(E)$ be the rational function satisfying $\text{div}(g_{P_1, P_2}) = (P_1) + (P_2) - (O) - (P_1 + P_2)$, where $P_1 + P_2$ denotes the sum of P_1 and P_2 on E and additions of the form $(P_1) + (P_2)$ denote formal additions in the divisor group. Miller's algorithm starts with $T = P$, and $f = 1$ is written as in Algorithm 1.

2.2. Edwards Curves. For $\text{char}(\mathbb{F}_q) \neq 2$, a twisted Edwards curve defined over $\mathbb{F}_q$ is given by

$$E_{a,d} : ax^2 + y^2 = 1 + dx^2y^2, \quad (2)$$

where a, d are distinct nonzero elements of $\mathbb{F}_q$. The projective closure of $E_{a,d}$ in $\mathbb{P}^2$ is

$$\{(X : Y : Z) \in \mathbb{P}^2 : aX^2Z^2 + Y^2Z^2 = Z^4 + dX^2Y^2\}. \quad (3)$$

This curve consists of the points (x, y) on the affine curve $E_{a,d}$, embedded as usual into $\mathbb{P}^2$ by $(x, y) \mapsto (x : y : 1)$, and extra points at infinity, that is, points when $Z = 0$. There are exactly two such points, namely, $\Omega_1 = (1 : 0 : 0)$ and $\Omega_2 = (0 : 1 : 0)$. These points are singular.

In fact, the twisted Edwards curve can be seen as the intersection of two quadric surfaces in space. That is, the twisted Edwards curve can be written as

$$SW_{a,d} : aX^2 + Y^2 - Z^2 - dW^2 = 0, \quad XY - ZW = 0. \quad (4)$$

More generally, every elliptic curve defined over a field K with $\text{char}(K) \neq 2$ can be written in this normal form over an extension of K . Set $O = (0 : 1 : 0 : 1)$ as the neutral element; the group law on (4) is given by

$$\begin{aligned} -(X : Y : W : Z) &= (-X : Y : -W : Z), \\ (X_1 : Y_1 : W_1 : Z_1) + (X_2 : Y_2 : W_2 : Z_2) &= (X_3 : Y_3 : W_3 : Z_3), \end{aligned} \quad (5)$$

where

$$\begin{aligned} X_3 &= (X_1Y_2 + Y_1X_2)(Z_1Z_2 - dW_1W_2), \\ Y_3 &= (Y_1Y_2 - aX_1X_2)(Z_1Z_2 + dW_1W_2), \\ W_3 &= (Y_1Y_2 - aX_1X_2)(X_1Y_2 + X_2Y_1), \\ Z_3 &= (Z_1Z_2 - dW_1W_2)(Z_1Z_2 + dW_1W_2). \end{aligned} \quad (6)$$

The point $O' = (0 : -1 : 0 : 1)$ has order 2. Note that the above formula is unified; that is, it can be applied to both adding two distinct points and doubling a point. The fast arithmetic on twisted Edwards curves given by (4) can be found in [18, 19].

We use $\mathbf{m}$ and $\mathbf{s}$ to denote the costs of multiplication and squaring in the base field $\mathbb{F}_q$, while $\mathbf{M}$ and $\mathbf{S}$ denote the costs of multiplication and squaring in the extension $\mathbb{F}_{q^k}$.

3. Geometric Interpretation of the Group Law on Twisted Edwards Curves

The aim of this section is to give the elaborate geometric interpretation of the group law on twisted Edwards curves which are seen as the intersection of two quadric surfaces in space. We consider projective planes which are given by homogeneous projective equations $\Pi = 0$. In this paper, we still use the symbol Π to denote projective planes. In fact, any plane Π intersects $SW_{a,d}$ at exactly four points. Although these planes are not functions on $SW_{a,d}$, their divisors can be well defined as

$$\text{div}(\Pi) = \sum_{R \in \Pi \cap SW_{a,d}} n_R(R), \quad (7)$$

where n_R is the intersection multiplicity of Π and $SW_{a,d}$ at R . Then the quotient of two projective planes is a well-defined function which gives principal divisor. As we will see, this divisor leads to the geometric interpretation of the group law.

When saying plane Π passes three points P_1, P_2 , and P_3 (not necessary distinct), we means that Π exactly satisfies $\text{div}(\Pi) \geq (P_1) + (P_2) + (P_3)$. In fact, by Riemann-Roch theorem or by explicit discussion on multiplicity, one can prove that there exists a unique plane which satisfies the above inequality. So we may denote this plane by Π_{P_1, P_2, P_3} from now on.

3.1. Group Law over the Twisted Edwards Curves. Abel-Jacobi theorem connects the group law with principal divisor. And we can get the lemma below.

Input: $r = \sum_{i=0}^{l-1} r_i 2^i$, where $r_i \in \{0, 1\}$. $P \in E(\mathbb{F}_q)$, $Q \in E(\mathbb{F}_{q^k})$.
Output: $f_r^{(q^k-1)/r}(Q)$
(1) $f \leftarrow 1, T \leftarrow P$
(2) **for** $i = l-2$ **down to** 0 **do** **do**
(3) $f \leftarrow f^2 \cdot g_{T,T}(Q), T \leftarrow 2T$
(4) **if** $r_i = 1$ **then then**
(5) $f \leftarrow f \cdot g_{T,P}(Q), T \leftarrow T + P$
(6) **end if**
(7) **end for**
(8) **return** $f^{(q^k-1)/r}$

ALGORITHM 1: Miller's algorithm.

Lemma 1. For twist Edwards curve $SW_{a,d}$ with neutral element $O = (0 : 1 : 0 : 1)$, let $O' = (0 : -1 : 0 : 1)$. Then 4 points (not necessarily distinct) P_1, P_2, P_3 , and P_4 satisfy $P_1 + P_2 + P_3 + P_4 = O'$ if and only if there is a plane Π with $\text{div}(\Pi) = (P_1) + (P_2) + (P_3) + (P_4)$.

Proof. Firstly, it is an easy calculation to get that $\text{div}(X - W) = 3(O) + (O')$.

Then the “if” part follows directly: if $\text{div}(\Pi) = (P_1) + (P_2) + (P_3) + (P_4)$, the principal divisor $\text{div}(\Pi/(X - W)) = (P_1) + (P_2) + (P_3) + (P_4) - 3(O) - (O')$ is translated into equation $P_1 + P_2 + P_3 + P_4 = O'$ by the Abel-Jacobi Theorem.

For the “only if” part, suppose that $P_1 + P_2 + P_3 + P_4 = O'$. Consider the plane Π_{P_1, P_2, P_3} ; we can assume that $\text{div}(\Pi_{P_1, P_2, P_3}) = (P_1) + (P_2) + (P_3) + (P'_4)$, so it derives $P_1 + P_2 + P_3 + P'_4 = O'$ from the “if” part. Then we get $P_4 = P'_4$; that is, $\text{div}(\Pi_{P_1, P_2, P_3}) = (P_1) + (P_2) + (P_3) + (P_4)$. $\square$

By this lemma, we can easily construct planes to give the group law. The fourth intersection of $\Pi_{P_1, O, O'}$ and the curve is $-P_1$, that is, the negative point of P_1 . The fourth intersection of $\Pi_{P_1, P_2, O'}$ and the curve is $-P_1 - P_2$, and its negative point gives $P_1 + P_2$. Actually, this geometric interpretation is parallel with the tangent and chord law for the cubic plane curves.

The neutral element we chose here is the same with that of [11], so we can claim that our explicit formulae for negative point, point addition, and point doubling are equivalent with which of [11].

4. Miller Function over $SW_{a,d}$

4.1. Construction of Miller Function. In this section we construct the Miller function over $SW_{a,d}$. Let P_1 and P_2 be two points on $SW_{a,d}$; by Lemma 1, we can get

$$\text{div}(\Pi_{P_1, P_2, O'}) = (P_1) + (P_2) + (O') + (-P_1 - P_2),$$

$$\text{div}(\Pi_{P_1 + P_2, O, O'}) = (P_1 + P_2) + (O) + (O') + (-P_1 - P_2). \quad (8)$$

Thus,

$$\text{div}\left(\frac{\Pi_{P_1, P_2, O'}}{\Pi_{P_1 + P_2, O, O'}}\right) = (P_1) + (P_2) - (P_1 + P_2) - (O). \quad (9)$$

So for addition steps, the Miller function $g_{T,P}$ over $SW_{a,d}$ can be given by setting $P_1 = T, P_2 = P$:

$$g_{T,P} = \frac{\Pi_{T,P,O'}}{\Pi_{T+P,O,O'}}. \quad (10)$$

For doubling steps, we set $P_1 = P_2 = T$, and the Miller function $g_{T,T}$ over $SW_{a,d}$ is given as

$$g_{T,T} = \frac{\Pi_{T,T,O'}}{\Pi_{2T,O,O'}}. \quad (11)$$

Then the remaining work is to compute the equation of these planes. The planes we use are of the form $C_X X + C_Y(Y + Z) + C_W W = 0$, because they always pass through $O' = (0 : -1 : 0 : 1)$. Thus we only need to compute C_X, C_Y , and C_W . To get a unified description, we use P_1, P_2 for both addition and doubling steps and consider $P_1 \neq P_2$ and $P_1 = P_2$, respectively, when necessary. Assume that $P_1 = (X_1 : Y_1 : W_1 : Z_1), P_2 = (X_2 : Y_2 : W_2 : Z_2)$, and $P_3 = P_1 + P_2 = (X_3 : Y_3 : W_3 : Z_3)$.

4.2. Equation of $\Pi_{P_1, P_2, O'}$ with $P_1 \neq P_2$. In the case that P_1, P_2 , and O' are pairwise distinct points on $SW_{a,d}$, by solving linear equations, we get the coefficients of the plane $\Pi_{P_1, P_2, O'}$ as follows:

$$\begin{aligned} C_X &= W_2(Z_1 + Y_1) - W_1(Z_2 + Y_2), \\ C_Y &= X_2 W_1 - X_1 W_2, \\ C_W &= X_1(Y_2 + Z_2) - X_2(Z_1 + Y_1). \end{aligned} \quad (12)$$

4.3. Equation of $\Pi_{P_1, P_2, O'}$ with $P_1 = P_2$. Suppose that $P_1 = P_2 \neq O'$. The tangent line to $SW_{a,d}$ at P_1 is the intersection of the tangent planes to $aX^2 + Y^2 - Z^2 - dW^2 = 0$ and $XY - ZW = 0$ at P_1 . The tangent plane to $aX^2 + Y^2 - Z^2 - dW^2 = 0$ at P_1 is $aX_1 X + Y_1 Y - Z_1 Z - dW_1 W = 0$. The tangent plane to $XY - ZW = 0$ at P_1 is $Y_1 X + X_1 Y - W_1 Z - Z_1 W = 0$. Then $\Pi_{P_1, P_1, O'}$ is of the form:

$$\begin{aligned} &\lambda(aX_1 X + Y_1 Y - Z_1 Z - dW_1 W) \\ &+ \mu(Y_1 X + X_1 Y - W_1 Z - Z_1 W) = 0. \end{aligned} \quad (13)$$

Note that $O' \in \Pi_{P_1, P_1, O'}$; that is, $\lambda(Y_1 + Z_1) + \mu(X_1 + W_1) = 0$. One can verify that $\lambda = -X_1$, $\mu = Z_1$ satisfy the equation. Hence, the equation of $\Pi_{P_1, P_1, O'}$ is

$$\begin{aligned} & -X_1(aX_1X + Y_1Y - Z_1Z - dW_1W) \\ & + Z_1(Y_1X + X_1Y - W_1Z - Z_1W) = 0. \end{aligned} \quad (14)$$

Then we can get the coefficients of $\Pi_{P_1, P_1, O'}$ as follows:

$$\begin{aligned} C_X &= Y_1Z_1 - aX_1^2, & C_Y &= X_1Z_1 - X_1Y_1, \\ C_W &= dX_1W_1 - Z_1^2. \end{aligned} \quad (15)$$

4.4. Equation of $\Pi_{P_3, O, O'}$. The plane $\Pi_{P_3, O, O'}$ can be regarded as a special case of $\Pi_{P_1, P_2, O'}$. For $P_3 \neq O, O'$, we have

$$C_X = W_3, \quad C_Y = 0, \quad C_W = -X_3. \quad (16)$$

Thus, we have $\Pi_{P_3, O, O'} : W_3X - X_3W = 0$.

5. Pairing Computation

In this section, we analysis steps in Miller's algorithm explicitly. For an addition step or doubling step, as is shown in Algorithm 1, each addition or doubling step consists of three parts: computing the point $T + P$ or $2T$ and the function $g_{T,P}$ or $g_{T,T}$, evaluating $g_{T,P}$ or $g_{T,T}$ at Q , and then updating the variable f by $f \leftarrow f \cdot g_{T,P}(Q)$ or by $f \leftarrow f^2 \cdot g_{T,T}(Q)$.

The updating part, as operation in $\mathbb{F}_{q^k}$, costs $1\mathbf{M}$ for addition step and $1\mathbf{M} + 1\mathbf{S}$ for doubling step. It is usually the main cost but with little room for optimization in one step. For the evaluating part, some standard methods such as denominator elimination and subfield simplification can be used, as we introduce below.

We assume that embedding degree k is even. Let δ be a generator of $\mathbb{F}_{q^k}$ over $\mathbb{F}_{q^{k/2}}$ with $\delta^2 \in \mathbb{F}_{q^{k/2}}$. Suppose that $Q' = (X_0 : Y_0 : W_0 : Z_0) \in SW_{a\delta^{-2}, d\delta^{-2}}(\mathbb{F}_{q^{k/2}})$; we can see that $Q = (X_0 : \delta Y_0 : W_0 : \delta Z_0) \in SW_{a,d}(\mathbb{F}_{q^k})$. If $P_3 = P_1 + P_2 \neq O, O'$, for evaluation of $g_{P_1, P_2}(Q)$, we have

$$\begin{aligned} g_{P_1, P_2}(Q) &= \frac{\Pi_{P_1, P_2, O'}(Q)}{\Pi_{P_3, O, O'}(Q)} \\ &= \frac{C_X X_0 + C_Y \delta(Y_0 + Z_0) + C_W W_0}{W_3 X_0 - X_3 W_0} \\ &= \frac{C_X(X_0/(Y_0 + Z_0)) + C_Y \delta + C_W(W_0/(Y_0 + Z_0))}{(W_3 X_0 - X_3 W_0)/(Y_0 + Z_0)} \\ &\in (C_X \theta + C_Y \delta + C_W \eta) \mathbb{F}_{q^{k/2}}^*, \end{aligned} \quad (17)$$

where $\theta = X_0/(Y_0 + Z_0)$ and $\eta = W_0/(Y_0 + Z_0)$. Note that $\theta, \eta \in \mathbb{F}_{q^{k/2}}$ and they are fixed during the whole computation, so they can be precomputed. The coefficients C_X, C_Y , and C_W

are in $\mathbb{F}_q$; thus the evaluation at Q given the coefficients of the plane can be computed in $k\mathbf{m}$ (multiplications by θ and η need $(k/2)\mathbf{m}$ each).

The computation of the coordinates of points and the coefficients of planes, as a part of much variety, is discussed, respectively, for addition and doubling step as follows.

5.1. Addition Steps. Let $P_1 = T$ and $P_2 = P$ be distinct points with $Z_1 Z_2 \neq 0$. By variant of formulae of (6) and (12), the explicit formulas for computing $P_3 = T + P$ and C_X, C_Y , and C_W are given as follows:

$$\begin{aligned} A &= X_1 \cdot X_2, & B &= Y_1 \cdot Y_2, & C &= Z_1 \cdot W_2, \\ D &= Z_2 \cdot W_1, & E &= W_1 \cdot W_2, \\ F &= (X_1 - Y_1) \cdot (X_2 + Y_2) - A + B, & G &= B + aA, \\ H &= D - C, \\ I &= D + C, & X_3 &= I \cdot F, & Y_3 &= G \cdot H, \\ Z_3 &= F \cdot G, & W_3 &= I \cdot H, \\ C_X &= (W_1 - Y_1) \cdot (W_2 + Y_2) - E + B + H, \\ C_W &= X_2 \cdot Z_1 - X_1 \cdot Z_2 - F, \\ C_Y &= (X_1 - W_1) \cdot (X_2 + W_2) - A + E. \end{aligned} \quad (18)$$

With these formulas, $T + P$ and C_X, C_Y , and C_W can be computed in $14\mathbf{m} + 1\mathbf{m}_c$, where $1\mathbf{m}_c$ is constant multiplication by a . For a mixed addition step, in which the base point P is chosen to have $Z_2 = 1$, the costs reduce to $12\mathbf{m} + 1\mathbf{m}_c$.

Therefore, the total costs of an addition step are $1\mathbf{M} + k\mathbf{m} + 14\mathbf{m} + 1\mathbf{m}_c$, while a mixed addition step costs $1\mathbf{M} + k\mathbf{m} + 12\mathbf{m} + 1\mathbf{m}_c$.

5.2. Doubling Steps. For $P_1 = P_2 = T$, $P_3 = 2T$. By the formulae of (6) and (15), our explicit formulas for computing $P_3 = 2T$ and C_X, C_Y, C_W are given as follows:

$$\begin{aligned} A &= X_1^2, & B &= Y_1^2, & C &= Z_1^2, \\ D &= aA, & E &= B + D, & F &= 2C - E, \\ G &= (X_1 + Y_1)^2 - A - B, & H &= (Y_1 + Z_1)^2 - B - C, \\ X_3 &= G \cdot F, & Y_3 &= E \cdot (B - D), & Z_3 &= E \cdot F, \\ W_3 &= G \cdot (B - D), \\ 2C_X &= H - 2D, & 2C_Y &= (X_1 + Z_1)^2 - A - C - G, \\ 2C_W &= d((X_1 + W_1)^2 - A) - C - E. \end{aligned} \quad (19)$$

By the above formulae, $2T$ and C_X, C_Y , and C_W can be computed in $4\mathbf{m} + 7\mathbf{s} + 2\mathbf{m}_c$, where $2\mathbf{m}_c$ are constant multiplications by a and d .

So total costs of our formulae for a doubling step are $1\mathbf{M} + 1\mathbf{S} + k\mathbf{m} + 4\mathbf{m} + 7\mathbf{s} + 2\mathbf{m}_c$, while the total costs of the formulae

for the doubling step proposed in [4] are $1\mathbf{M} + 1\mathbf{S} + k\mathbf{m} + 6\mathbf{m} + 5\mathbf{s} + 2\mathbf{m}_c$, where $2\mathbf{m}_c$ are both constant multiplication by a .

6. High-Degree Twists

Let $d \mid k$, an elliptic curve E' over $\mathbb{F}_{q^{k/d}}$ is called a twist of degree d of $E/\mathbb{F}_{q^{k/d}}$ if there is an isomorphism $\psi : E' \rightarrow E$ defined over $\mathbb{F}_{q^k}$, and this is the smallest extension of $\mathbb{F}_{q^{k/d}}$ over which ψ is defined. Depending on the j -invariant $j(E)$ of E , there exist twists of degree at most 6, since $\text{char}(\mathbb{F}_q) > 3$. Pairing friendly curves with twists of degree higher than 2 arise from constructions with j -invariants $j(E) = 0$ and $j(E) = 1728$.

6.1. Edwards Curves with $j = 1728$. For twisted Edwards curve $E_{a,-a} : ax^2 + y^2 = 1 - ax^2y^2$, the j -invariant equals to 1728; hence, there exist twists of degree 4. The case $a = 1$ is the “classical” Edwards curve $x^2 + y^2 = 1 - x^2y^2$ with complex multiplication $D = -4$ [20].

Lemma 2. Assume that $4 \mid k$, δ is a generator of $\mathbb{F}_{q^k}$ over $\mathbb{F}_{q^{k/4}}$ and $\delta^4 \in \mathbb{F}_{q^{k/4}}$, which implies $\delta^2 \in \mathbb{F}_{q^{k/2}}$. Then the Weierstrass curve

$$W_a : \frac{2}{a}v^2 = u^3 + \frac{1}{\delta^4}u \quad (20)$$

is a twist of degree 4 over $\mathbb{F}_{q^{k/4}}$ of $E_{a,-a}$. The isomorphism can be given as

$$\begin{aligned} \psi : W_a &\longrightarrow E_{a,-a} \\ (u, v) &\longmapsto (x, y) = \left(\frac{u}{\delta v}, \frac{\delta^2 u - 1}{\delta^2 u + 1} \right). \end{aligned} \quad (21)$$

Proof. Firstly, we prove that ψ is well defined; that is, $\psi(u, v) \in E_{a,-a}$. Note that

$$\frac{1}{x^2} = \frac{\delta^2 v^2}{u^2} = \frac{a}{2\delta^2 u} (\delta^4 u^2 + 1). \quad (22)$$

We have

$$\frac{1}{x^2} - a = \frac{a}{2\delta^2 u} (\delta^2 u - 1)^2, \quad \frac{1}{x^2} + a = \frac{a}{2\delta^2 u} (\delta^2 u + 1)^2. \quad (23)$$

Then

$$\frac{1 - ax^2}{1 + ax^2} = \left(\frac{\delta^2 u - 1}{\delta^2 u + 1} \right)^2 = y^2, \quad \text{thus } ax^2 + y^2 = 1 - ax^2y^2. \quad (24)$$

Moreover, it can be easily checked that ψ is invertible and satisfies $\psi(O) = O$; that is, ψ is an isomorphism. Besides, the minimal field that ψ can be defined over is $\mathbb{F}_{q^k}$ which has degree 4 over $\mathbb{F}_{q^{k/4}}$. Hence, the twist degree is 4. $\square$

For $Q' \in W_a(\mathbb{F}_{q^{k/4}})$, we have $(x_Q, y_Q) = \psi(Q') \in E_{a,-a}(\mathbb{F}_{q^k})$. Then its corresponding point $Q \in SW_{a,-a}(\mathbb{F}_{q^k})$ can

be given as $(X_Q : Y_Q : W_Q : Z_Q) = (x_Q : y_Q : x_Q y_Q : 1)$. One can check by substitution that

$$\begin{aligned} \frac{X_Q + W_Q}{Y_Q + Z_Q} &= x_Q = \frac{u}{\delta v}, \\ \frac{X_Q - W_Q}{Y_Q + Z_Q} &= x_Q \cdot \frac{1 - y_Q}{1 + y_Q} = \frac{1}{\delta^3 v}. \end{aligned} \quad (25)$$

For $\theta = u/(2v)$ and $\eta = 1/(2v)$, we have $X_Q/(Y_Q + Z_Q) = \theta\delta^{-1} + \eta\delta^{-3}$ and $W_Q/(Y_Q + Z_Q) = \theta\delta^{-1} - \eta\delta^{-3}$ with $\theta, \eta \in \mathbb{F}_{q^{k/4}}$. Then for the evaluation of $g_{P_1, P_2}(Q)$ with $P_3 = P_1 + P_2 \neq O, O'$, we get

$$\begin{aligned} g_{P_1, P_2}(Q) &= \frac{\Pi_{P_1, P_2, O'}(Q)}{\Pi_{P_3, O, O'}(Q)} \\ &= \frac{C_X X_Q + C_Y (Y_Q + Z_Q) + C_W W_Q}{W_3 X_Q - X_3 W_Q} \\ &= \frac{C_X (\theta\delta^{-1} + \eta\delta^{-3}) + C_Y + C_W (\theta\delta^{-1} - \eta\delta^{-3})}{W_3 (\theta\delta^{-1} + \eta\delta^{-3}) - X_3 (\theta\delta^{-1} - \eta\delta^{-3})} \\ &= \frac{(C_X - C_W)\eta + (C_X + C_W)\theta\delta^2 + C_Y\delta^3}{(W_3 + X_3)\eta + (W_3 - X_3)\theta\delta^2} \\ &\in ((C_X - C_W)\eta + (C_X + C_W)\theta\delta^2 + C_Y\delta^3) \mathbb{F}_{q^{k/2}}^*. \end{aligned} \quad (26)$$

So we can reduce $g_{P_1, P_2}(Q)$ to $(C_X - C_W)\eta + (C_X + C_W)\theta\delta^2 + C_Y\delta^3$. Moreover we may precompute θ and η since they are fixed during the whole computation. When $C_X, C_Y, C_W \in \mathbb{F}_q$, and $\theta, \eta \in \mathbb{F}_{q^{k/4}}$ are given, the evaluation at Q can be computed in $(k/2)\mathbf{m}$, with $(k/4)\mathbf{m}$ each for multiplications by θ and η .

The high twist not only reduces the cost of evaluating $g(Q)$ but also the cost of updating f , which is the main multiplication in Miller's algorithm as a multiplication in $\mathbb{F}_{q^k}$. Consider $\mathbb{F}_{q^k}$ as an $\mathbb{F}_{q^{k/4}}$ -vector space with bases $1, \delta, \delta^2$, and δ^3 . Then an arbitrary element $\alpha \in \mathbb{F}_{q^k}$ can be denoted as $a_0 + a_1\delta + a_2\delta^2 + a_3\delta^3$ with $a_i \in \mathbb{F}_{q^{k/4}}$, $i = 0, 1, 2, 3$. And the reduced value of $g(Q)$ we have gotten above can be denoted as $\beta = b_0 + b_2\delta^2 + b_3\delta^3$, where $b_3 \in \mathbb{F}_q$ and $b_0, b_2 \in \mathbb{F}_{q^{k/4}}$. When using the Schoolbook method, multiplying α by β costs $4 \cdot (k/4)\mathbf{m}$ for computing $a_i \cdot b_j$, $i = 0, 1, 2, 3$ and costs $8(k/4)^2\mathbf{m}$ for $a_i \cdot b_0$ and $a_i \cdot b_2$. The total cost $(k^2/2 + k)\mathbf{m}$ equals to $((1/2) + (1/k))\mathbf{M}$, considering that a general multiplication in $\mathbb{F}_{q^k}$ costs $\mathbf{M} = k^2\mathbf{m}$. Namely, the quartic twist may reduce the cost of the main multiplication in Miller's algorithm to $((1/2) + (1/k))\mathbf{M}$.

Therefore, the *addition step* costs $((1/2) + (1/k))\mathbf{M} + ((k/2) + 14)\mathbf{m} + 1\mathbf{m}_c$, where $1\mathbf{m}_c$ is constant multiplication by a . For a mixed addition step, the costs reduce to $((1/2) + (1/k))\mathbf{M} + ((k/2) + 12)\mathbf{m} + 1\mathbf{m}_c$.

The *doubling step* costs $((1/2) + (1/k))\mathbf{M} + 1\mathbf{S} + ((k/2) + 4)\mathbf{m} + 7\mathbf{s} + 2\mathbf{m}_c$, where $2\mathbf{m}_c$ are constant multiplications by a and d .

6.2. Edwards Curves with $j = 0$. The twisted Edwards curve $ax^2 + y^2 = 1 + dx^2y^2$ has j -invariant $j_{a,d} = 16(a^2 + 14ad + d^2)^3 / ad(a-d)^4$; hence, $j_{a,d} = 0$ if and only if $a = (-7 \pm 4\sqrt{3})d$. Note that 3 is a square in finite field $\mathbb{F}_q$ if and only if $q \equiv \pm 1 \pmod{12}$. Now we assume that $q \equiv \pm 1 \pmod{12}$ and a, d satisfy the relation $a = (-7 \pm 4\sqrt{3})d$. Then Edwards curve $E_{a,d} : ax^2 + y^2 = 1 + dx^2y^2$ has j -invariant equal to 0; hence, there exist twists of degree 6. The case $a = 1$ is the Edwards curve $x^2 + y^2 = 1 - (7 + 4\sqrt{3})x^2y^2$ with complex multiplication $D = -3$ [20].

We denote that $M = 2(a+d)/(a-d)$ and $N = 4/(a-d)$ when given a, d .

Lemma 3. Assume that $6 \mid k$, δ is a generator of $\mathbb{F}_{q^k}$ over $\mathbb{F}_{q^{k/6}}$ with $\delta^6 \in \mathbb{F}_{q^{k/6}}$, which implies $\delta^2 \in \mathbb{F}_{q^{k/2}}$ and $\delta^3 \in \mathbb{F}_{q^{k/3}}$. Then the Weierstrass elliptic curve

$$W_{MN} : v^2 = u^3 - \frac{M^3N^3}{27}\delta^6 \quad (27)$$

is a twist of degree 6 over $\mathbb{F}_{q^{k/6}}$ of $E_{a,d}$. The isomorphism can be given as

$$\begin{aligned} \psi : W_a &\longrightarrow E_{a,d}, \\ (u, v) &\longmapsto (x, y) \\ &= \left(\frac{N\delta(3u - MN\delta^2)}{3v}, \frac{3u - MN\delta^2 - 3N\delta^2}{3u - MN\delta^2 + 3N\delta^2} \right). \end{aligned} \quad (28)$$

Proof. Firstly, we check that ψ is well defined; that is, $\psi(u, v) \in E_{a,d}$. We denote that $u' = u - (MN\delta^2)/3$, then

$$\begin{aligned} v^2 &= u^3 - \frac{M^3N^3\delta^6}{27} = u' \left(u'^2 + MN\delta^2u' + \frac{M^2N^2\delta^4}{3} \right), \\ x &= \frac{N\delta u'}{v}, \quad y = \frac{u' - N\delta^2}{u' + N\delta^2}. \end{aligned} \quad (29)$$

Note that

$$\frac{1}{x^2} = \frac{v^2}{N^2\delta^2u'^2} = \frac{1}{N^2\delta^2u'} \left(u'^2 + MN\delta^2u' + \frac{M^2N^2\delta^4}{3} \right). \quad (30)$$

Since $M - Na = -2$, $M - Nd = 2$, and $M^2 = 3$, we have

$$\begin{aligned} \frac{1}{x^2} - a &= \frac{1}{N^2\delta^2u'} (u' - N\delta^2)^2, \\ \frac{1}{x^2} - d &= \frac{1}{N^2\delta^2u'} (u' + N\delta^2)^2. \end{aligned} \quad (31)$$

Thus

$$\begin{aligned} \frac{1 - ax^2}{1 - dx^2} &= \left(\frac{u' - N\delta^2}{u' + N\delta^2} \right)^2 \\ &= y^2, \quad \text{that is, } ax^2 + y^2 = 1 + dx^2y^2. \end{aligned} \quad (32)$$

Moreover, it can be easily checked that ψ is invertible and satisfies $\psi(O) = O$; that is, ψ is an isomorphism. Besides, the minimal field that ψ can be defined over is $\mathbb{F}_{q^k}$ which has degree 6 over $\mathbb{F}_{q^{k/6}}$. Hence, the twist degree is 6. $\square$

For $Q' \in W_{MN}(\mathbb{F}_{q^{k/6}})$, we have $(x_Q, y_Q) = \psi(Q') \in E_{a,d}(\mathbb{F}_{q^k})$. Then its corresponding point $Q \in SW_{a,d}(\mathbb{F}_{q^k})$ can be given as $(X_Q : Y_Q : W_Q : Z_Q) = (x_Q : y_Q : x_Qy_Q : 1)$. One can check by substitution that

$$\begin{aligned} \frac{X_Q + W_Q}{Y_Q + Z_Q} &= x_Q = \frac{Nu}{v}\delta - \frac{MN^2}{3v}\delta^3, \\ \frac{X_Q - W_Q}{Y_Q + Z_Q} &= x_Q \cdot \frac{1 - y_Q}{1 + y_Q} = \frac{N^2}{v}\delta^3. \end{aligned} \quad (33)$$

For $\theta = (Nu/2v)\delta^6$ and $\eta = (N^2/6v)\delta^6$, we have

$$\begin{aligned} \frac{X_Q}{Y_Q + Z_Q} &= \theta\delta^{-5} + (3 - M)\eta\delta^{-3}, \\ \frac{W_Q}{Y_Q + Z_Q} &= \theta\delta^{-5} - (3 + M)\eta\delta^{-3} \end{aligned} \quad (34)$$

with $\theta, \eta \in \mathbb{F}_{q^{k/6}}$. Then for the evaluation of $g_{P_1, P_2}(Q)$ with $P_3 = P_1 + P_2 \neq O, O'$, we get

$$\begin{aligned} g_{P_1, P_2}(Q) &= \frac{\Pi_{P_1, P_2, O'}(Q)}{\Pi_{P_3, O, O'}(Q)} \\ &= \frac{C_X X_Q + C_Y (Y_Q + Z_Q) + C_W W_Q}{W_3 X_Q - X_3 W_Q} \\ &= \frac{C_X (X_Q / (Y_Q + Z_Q)) + C_Y + C_W (W_Q / (Y_Q + Z_Q))}{W_3 (X_Q / (Y_Q + Z_Q)) - X_3 (W_Q / (Y_Q + Z_Q))} \\ &= (C_X (\theta\delta^{-5} + (3 - M)\eta\delta^{-3}) + C_Y \\ &\quad + C_W (\theta\delta^{-5} - (3 + M)\eta\delta^{-3})) \\ &\quad \times (W_3 (\theta\delta^{-5} + (3 - M)\eta\delta^{-3}) \\ &\quad - X_3 (\theta\delta^{-5} - (3 + M)\eta\delta^{-3}))^{-1} \\ &= ((C_X + C_W)\theta \\ &\quad + (3(C_X - C_W) - M(C_X + C_W))\eta\delta^2 + C_Y\delta^5) \\ &\quad \times ((W_3 - X_3)\theta \\ &\quad + (3(W_3 + X_3) - M(W_3 - X_3))\eta\delta^2)^{-1} \\ &\in ((C_X + C_W)\theta + (3(C_X - C_W) - M(C_X + C_W))\eta\delta^2 \\ &\quad + C_Y\delta^5) \mathbb{F}_{q^{k/2}}^*. \end{aligned} \quad (35)$$

TABLE 1

	DBL	mADD	ADD
Arène et al. [4]	$1M + 1S + km + 6m + 5s + 2m_c$	$1M + km + 12m + 1m_c$	$1M + km + 14m + 1m_c$
This paper $j \neq 0, 1728$	$1M + 1S + km + 4m + 7s + 2m_c$	$1M + km + 12m + 1m_c$	$1M + km + 14m + 1m_c$
This paper $j = 1728$	$(1/2 + 1/k)M + 1S + (k/2)m + 4m + 7s + 2m_c$	$(1/2 + 1/k)M + (k/2)m + 12m + 1m_c$	$(1/2 + 1/k)M + (k/2)m + 14m + 1m_c$
This paper $j = 0$	$(1/3 + 1/k)M + 1S + (k/3)m + 4m + 7s + 3m_c$	$(1/3 + 1/k)M + (k/3)m + 12m + 2m_c$	$(1/3 + 1/k)M + (k/3)m + 14m + 2m_c$

So we can reduce $g_{P_1, P_2}(Q)$ to the representative in the last line. Moreover we may precompute θ and η since they are fixed during the whole computation. When $C_X, C_Y, C_W \in \mathbb{F}_q$, and $\theta, \eta \in \mathbb{F}_{q^{k/6}}$ are given, the evaluation at Q can be computed in $(k/3)m + m_c$, with $(k/6)m$ each for multiplications by θ and η and a constant multiplication by $M = 2(a + d)/(a - d)$.

Similarly with the $j = 1728$ case, consider $\mathbb{F}_{q^k}$ as an $\mathbb{F}_{q^{k/6}}$ -vector space with bases $1, \delta, \delta^2, \dots, \delta^5$. Then an arbitrary element $\alpha \in \mathbb{F}_{q^k}$ can be denoted as $a_0 + a_1\delta + a_2\delta^2 + \dots + a_5\delta^5$ with $a_i \in \mathbb{F}_{q^{k/6}}, i = 0, 1, \dots, 5$. And the reduced $g(Q)$ we have gotten above can be denoted as $\beta = b_0 + b_2\delta^2 + b_5\delta^5$, where $b_5 \in \mathbb{F}_q$ and $b_0, b_2 \in \mathbb{F}_{q^{k/6}}$. When using the Schoolbook method, multiplying α by β costs $6 \cdot (k/6)m$ for computing $a_i \cdot b_5, i = 0, 1, 2, 3$ and costs $12(k/6)^2m$ for $a_i \cdot b_0$ and $a_i \cdot b_2$. The total cost $((k^2/3) + k)m$ equals to $((1/3) + (1/k))M$, considering that a general multiplication in $\mathbb{F}_{q^k}$ costs $M = k^2m$. Namely, the sextic twist may reduce the cost of the main multiplication in Miller's algorithm to $((1/3) + (1/k))M$.

Therefore, the *addition step* costs $((1/3) + (1/k))M + ((k/3) + 14)m + 2m_c$, where $2m_c$ are multiplications by a and $2(a + d)/(a - d)$. For a mixed addition step, the costs reduce to $((1/3) + (1/k))M + ((k/3) + 12)m + 2m_c$.

The *doubling step* costs $((1/3) + (1/k))M + 1S + ((k/3) + 4)m + 7s + 3m_c$, where $3m_c$ are multiplications by a, d , and $2(a + d)/(a - d)$.

Table 1 shows the concrete comparison for doubling step (DBL), mixed addition step (mADD), and addition step (ADD).

7. Conclusion

In this paper, we propose an elaborate geometry approach to explain the group law on Edwards curves which are seen as the intersection of two quadric surfaces in space. Using the geometric interpretation of the group law, we obtain the Miller function of Tate pairing computation on twisted Edwards curves. Then we present the explicit formulae for pairing computation on twisted Edwards curves. The doubling step of our formulae is a little faster than that in [4]. Finally, to improve the efficiency, we present quartic and sextic twists on twisted Edwards curves. By using high twists, the costs of substituting in $j = 1728$ case and $j = 0$ case can be reduced to a half and a third, respectively. Above all, it is interesting to consider more efficient formulae for pairing computation on twist Edwards curves.
