In the paper are presented the expressions for all network functions of common-ground, uniform passive ladders having, in general, complex terminations at both their ends. The Elmore’s delay and rise times calculated for selected types of RLC ladders have indicated their slight deviation from delay and rise times obtained according to their classical definitions. For common-ground, integrating type RC ladder with voltage-step input, the Elmore’s delay- and rise-times are produced in closed-form, both for ladder nodes and points. Furthermore, it is proposed a particular common-ground, uniform RLC ladder being amenable to application as delay line for pulsed and analog input signals. For this ladder, the Elmore’s delay and rise times relating to their node voltages are produced in a closed-form, enabling thus with the realization of artificial (a) pulse delay line with arbitrarily and independently specified overall Elmore’s delay and rise times and (b) true delay line with arbitrarily specified delay time for frequency bounded analog and/or pulsed input signals. In cases (a) and (b), precise procedures are formulated for calculation of ladder length and of all its RLC parameters. The obtained results are illustrated with several practical examples and are, also, verified through PSpice simulation.

1. Introduction

Modeling of digital MOS circuits by RC networks has become a well-accepted practice for estimating delays [1–6]. In digital integrated circuits, signal propagation delay through conducting paths with distributed resistance and capacitance is frequently a significant part of the total delay. These conducting paths, or “interconnections,” can be modeled quite accurately by nonuniform, branched RC ladder networks, also known as “RC trees” [3]. Computationally simple bounds for signal delay in linear RC tree networks were found in [3] and have been used in several practical MOS timing analyzers reported in [6], but certain circuits used in MOS logic cannot be modeled as RC trees since they contain one or more closed loops of resistors, and these general RC networks are being referred to as “RC meshes”. In these networks, the time delay defined according to Elmore [7] is proved to be the valid estimate, and this fact has been used in [5] to advantage in an approach to MOS timing analysis of general RC networks containing RC meshes. Simple closed-form bounds for signal propagation delay in linear RC tree models for MOS interconnections derived in [3] are, also, valid for the more general class of linear networks known as RC meshes, which are useful as models for portions of MOS logic circuits that cannot be represented as RC trees [6].

Elmore’s delay is an extremely popular timing-performance metric which is used at all levels of electronic circuit design automation, particularly for RC tree analysis. The widespread usage of this metric is mainly attributable to its property of being a simple analytical function of
circuit parameters, and its drawbacks are the uncertainty of accuracy and restriction to being the estimate only for the step-response delay. An extension of Elmore's delay definition has been proposed in [8] to accommodate the effect of nonunit-step (slow) excitations and to handle multiple sources of excitation, in order to show that delay estimation for slow excitations is no harder than for the unit-step input. In [9] it has been shown that this extension of Elmore's delay time offers a provision to deal with slow varying excitations in timing analysis of MOS pass transistor networks. In addition, in [10] it has been reported that Elmore's delay is an absolute upper bound on the actual 50% delay of an RC tree response. Also in [10], it has been proved that this bound holds for input signals other than steps and that actual delay asymptotically approaches to Elmore’s delay as the input signal rise-time increases. It has been emphasized in [11] that RC tree step responses always are monotonic, and this is why Elmore’s definitions of both delay and rise time [7] are applicable on complex RC tree networks.

In this paper we will firstly derive the general, closed-form expressions for input and transfer functions of common-ground, uniform, and passive ladders with complex double terminations, making a distinction between the signal transfer to ladder nodes and to its points. Then, simplifications of the obtained results are produced for ladders with seven specific pairs of complex double terminations being interesting from the practical point of view. Thereafter, for a uniform, common-ground RLC ladder with (a) a relation between its parameters resembling to analogous relation between per-unit-length parameters of distortionless transmission line and (b) symmetric, resistive double termination resembling to characteristic impedance of distortionless line [12], it will be shown that Elmore’s delay and rise times for point voltage transmittances can be efficiently calculated (but not in the closed form) by using of the numerical scheme proposed herein. In this case, we will see that the obtained numerical values for Elmore’s times differ slightly from the delay and rise times obtained according to their classical definitions and by using pspice simulation when ladder is excited by a step voltage.

For the integrating type of distributed RC impedance, common-ground ladder as a model of two-wire line, it has been suggested that it might be used as a true pulse delay line [13], provided that, Schmitt triggers are used for reshaping the delayed and edge-distorted transmitted signals. This type of delay line with step-input excitation has already been thoroughly investigated in [14]—where Elmore’s delay time is given in closed form only for ladder nodes, and for Elmore’s rise time is offered a conjecture relating to its lower bound for overall network. Elmore’s rise time for all nodes of integrating, RC open-circuited ladder are given in closed form in [15] and the obtaining of Elmore’s delay and rise times both for nodes and points is discussed to some extent in [16]—for other types of open-circuited ladders. In this paper, we are going to formulate the explicit closed-form expressions for Elmore’s delay and rise times both for the node and point voltages of integrating open circuited, common-ground RC ladder and will conclude that this type of network is not recommendable for pulse delay line in its own right, since Elmore’s rise time of each point voltage is not less than the twice of its delay-time.

And finally, we will propose a type of uniform, common-ground RLC ladder amenable for application as delay line both for pulsed and/or analog input signals. Elmore’s delay and rise times of this ladder relating to the node voltage transmittances are produced in closed form, opening thus with the following possibilities in ladder realization:

(i) for pulsed inputs, the overall Elmore delay and rise times may be specified arbitrarily,

(ii) for pulsed inputs, the overall ladder length (i.e., the minimum necessary number of sections) is calculated straightforwardly by using only the overall Elmore delay and rise times,

(iii) the ladder RL parameters are calculated uniquely from the assumed nonminimal ladder length, overall Elmore delay time, and the assumed capacitance values,

(iv) for realization of true delay for pulsed and/or analog input signals with arbitrary variation in time, minimum ladder length is calculated from the specified true delay time (which asymptotically tends to Elmore’s delay time when the number of sections tends to infinity) and maximum frequency in the spectrum of the signal being transmitted along the ladder purporting to represent delay line. And again, as in (iii), the ladder RL parameters are determined from the ladder length, overall ladder true delay time (being approximately equal to Elmore’s delay time), and the assumed capacitance values. The previous approach and obtained results are illustrated and verified with realization examples of large true delay time (=5 [ms]) for pulsed, sine, distorted sine, CAM, FM; and chirp frequency and sweep amplitude input signals.

Recall that in network synthesis the ladder topology is a preferable one, since it has very low sensitivity to variations of RLC parameters [16, 17].

2. Network Functions of Common-Ground, Uniform, and Passive RLC Ladders

Consider a uniform, grounded, and passive RLC ladder in Figure 1 with N identical sections, whose impedances \( Z_1 = Z_1(s) \) and \( Z_2 = Z_2(s) \) are positive real rational functions in complex frequency \( s = \sigma + j \omega \) (\( j := \sqrt{-1} \)). There on are denoted the Laplace transforms \( E = E(s) \) of the voltage excitation \( e = e(t) \), \( U_k = U_k(s) \) and \( I_k = I_k(s) \) of the point voltages \( u_k = u_k(t) \) and currents \( i_k = i_k(t) \) (\( k = 0, N \)), and \( U'_m = U'_m(s) \) and \( I'_m = I'_m(s) \) of node voltages \( u'_m = u'_m(t) \) and currents \( i'_m = i'_m(t) \) (\( m = 0, N - 1 \)). The internal impedances of the voltage excitation (voltage generator) and the load are \( Z_g = Z_g(s) \) and \( Z_L = Z_L(s) \), respectively. All the initial conditions associated to the network reactive (LC) elements are assumed to be zero.
For ladder in Figure 1, the mesh transform equations for its \( n \)th section \((n = 1, N)\) read

\[
\begin{align*}
(Z_1 + Z_2) \cdot I_{n-1} - Z_2 \cdot I_n &= U_{n-1}, \\
Z_2 \cdot I_{n-1} - (Z_1 + Z_2) \cdot I_n &= U_n,
\end{align*}
\]

or in the recurrence form

\[
\begin{bmatrix} U_n \\ I_n \end{bmatrix} = \begin{bmatrix} 1 + \frac{Z_1}{Z_2} & -\left(\frac{Z_2^2}{Z_2} + 2 \cdot Z_1\right) \\
-\frac{1}{Z_2} & 1 + \frac{Z_1}{Z_2} \end{bmatrix} \begin{bmatrix} U_{n-1} \\ I_{n-1} \end{bmatrix},
\]

(1)

The boundary values of voltages and currents in the set of matrix difference equations (1) are \((U_0, I_0)\) and \((U_N, I_N)\). For \( n = 0, N \), from (1) it immediately follows that

\[
\begin{bmatrix} U_n \\ I_n \end{bmatrix} = \begin{bmatrix} 1 + \frac{Z_1}{Z_2} & -\left(\frac{Z_2^2}{Z_2} + 2 \cdot Z_1\right) \\
-\frac{1}{Z_2} & 1 + \frac{Z_1}{Z_2} \end{bmatrix} \begin{bmatrix} U_0 \\ I_0 \end{bmatrix},
\]

(2)

where \( U_0 = E - Z_g \cdot I_0 \) and \( U_N = Z_L \cdot I_N \).

Since the roots \((\lambda_1, \lambda_2)\) of the characteristic equation corresponding to \( 2 \times 2 \) matrix appearing in (1),

\[
\det \begin{bmatrix} 1 + \frac{Z_1}{Z_2} & -\left(\frac{Z_2^2}{Z_2} + 2 \cdot Z_1\right) \\
-\frac{1}{Z_2} & 1 + \frac{Z_1}{Z_2} \end{bmatrix} - \lambda \cdot U_2 = 0
\]

(3)

satisfy the relations \( \lambda_1 + \lambda_2 = 2 \cdot (Z_1/Z_2 + 1) \) and \( \lambda_1 \cdot \lambda_2 = 1 \), then by taking for convenience \( \lambda_1 := \exp(\tau) \) and \( \lambda_2 := \exp(-\tau) \), we obtain \( \cosh(\tau) = 1 + Z_1/Z_2 \). By using Cayley-Hamilton's theorem we may put

\[
\begin{bmatrix} 1 + \frac{Z_1}{Z_2} & -\left(\frac{Z_2^2}{Z_2} + 2 \cdot Z_1\right) \\
-\frac{1}{Z_2} & 1 + \frac{Z_1}{Z_2} \end{bmatrix}^n = \begin{bmatrix} 1 + Z_1/Z_2 & -\left(Z_1^2/Z_2^2 + 2 \cdot Z_1\right) \\
-\frac{1}{Z_2} & 1 + Z_1/Z_2 \end{bmatrix},
\]

(4)

where the "constants" \( A_0 \) and \( A_1 \) are determined from system of equations \([\exp(\tau)]^n = A_0 + A_1 \cdot \exp(\tau)\) and \([\exp(-\tau)]^n = A_0 + A_1 \cdot \exp(-\tau)\), whose solution is \( A_0 = -\sinh((n-1) \cdot \tau) / \sinh(\tau) \) and \( A_1 = \sinh(n \cdot \tau) / \sinh(\tau) \).

By substituting \( A_0 \) and \( A_1 \) in (4) and bearing in mind that

\[
\begin{align*}
1 + \frac{Z_1}{Z_2} &= \cosh(\tau), \\
-Z_2 \cdot \left(Z_1 + Z_2\right) &= -Z_2 \cdot \sinh^2(\tau),
\end{align*}
\]

(5)

we finally obtain from (2) and (4) for \( n = 0, N \) that

\[
\begin{bmatrix} U_n \\ I_n \end{bmatrix} = \begin{bmatrix} 1 + \frac{Z_1}{Z_2} & -\left(\frac{Z_2^2}{Z_2} + 2 \cdot Z_1\right) \\
-\frac{1}{Z_2} & 1 + \frac{Z_1}{Z_2} \end{bmatrix} \begin{bmatrix} U_0 \\ I_0 \end{bmatrix} = \begin{bmatrix} \cosh(n \cdot \tau) & -Z_2 \cdot \sinh(n \cdot \tau) \cdot \sinh(n \cdot \tau) \\
\sinh(n \cdot \tau) \cdot \sinh(\tau) & \cosh(n \cdot \tau) \end{bmatrix} \begin{bmatrix} U_0 \\ I_0 \end{bmatrix},
\]

(6)
Since uniform ladder sections are electrically reciprocal, then their characteristic impedance \( Z_c \) and the quantity \( Z_c \cdot \sinh(\tau) \) can easily be produced in the form

\[
Z_c = Z_2 \cdot \sinh(\tau) = \sqrt{Z_1 \cdot (Z_1 + 2 \cdot Z_2)}.
\]

\[
Z_c \cdot \sinh(\tau) = Z_2 \cdot \sinh^2(\tau)
= Z_2 \cdot \left[ \cosh^2(\tau) - 1 \right] = Z_1 \cdot \left( \frac{Z_1}{Z_2} + 2 \right). \tag{7}
\]

For the ladder depicted in Figure 1, the complete set of the network immittance and voltage/current transmittance functions can be produced, by using the relations (2), (6), and (7):

\[
\begin{align*}
\frac{I_n}{E} &= \left( \cosh \left( (N-n) \cdot \tau \right) + \frac{Z_L}{Z_c} \cdot \sinh \left( (N-n) \cdot \tau \right) \right) \times \left( \left( Z_g + Z_L \right) \cdot \cosh \left( N \cdot \tau \right) + \left( Z_c + Z_g \cdot Z_L \right) \cdot \sinh \left( N \cdot \tau \right) \right)^{-1}, \\
\frac{I_n}{I_0} &= \left( Z_c \cdot \cosh \left( (N-n) \cdot \tau \right) + Z_L \cdot \sinh \left( (N-n) \cdot \tau \right) \right) \\
&\quad \times \left( Z_c \cdot \cosh \left( N \cdot \tau \right) + Z_L \cdot \sinh \left( N \cdot \tau \right) \right), \\
\frac{U_n}{E} &= \left( Z_L \cdot \cosh \left( (N-n) \cdot \tau \right) + Z_L \cdot \sinh \left( (N-n) \cdot \tau \right) \right) \times \left( \left( Z_g + Z_L \right) \cdot \cosh \left( N \cdot \tau \right) + \left( Z_c + Z_g \cdot Z_L \right) \cdot \sinh \left( N \cdot \tau \right) \right)^{-1}, \\
\frac{U_n}{U_0} &= \left( Z_L \cdot \cosh \left( (N-n) \cdot \tau \right) + Z_L \cdot \sinh \left( (N-n) \cdot \tau \right) \right) \times \left( Z_L \cdot \cosh \left( N \cdot \tau \right) + Z_c \cdot \sinh \left( N \cdot \tau \right) \right)^{-1}, \\
\frac{U_n}{U_m} &= \left( Z_L \cdot \cosh \left( (N-n) \cdot \tau \right) + Z_L \cdot \sinh \left( (N-n) \cdot \tau \right) \right) \times \left( Z_L \cdot \cosh \left( N \cdot \tau \right) + Z_c \cdot \sinh \left( N \cdot \tau \right) \right)^{-1}.
\end{align*}
\]

Since \( Z_1 = Z_c \cdot \sinh(\tau) /[1 + \cosh(\tau)] = Z_c \cdot \tanh(\tau/2) \), then the voltages and currents of impedances \( Z_2 \) connecting the middle nodes of ladder sections \( M_m \) to common-node \( O \) (Figure 1) are given as

\[
\begin{align*}
\frac{U_m'}{Z_2} &= \frac{U_m + U_{m+1}}{Z_1 + 2 \cdot Z_2}, \\
\frac{I_m'}{U_m} &= \left( \left( Z_L - Z_1 \right) \cdot \cosh \left( ((N-m) \cdot \tau \right) + \left[ Z_c - Z_L \cdot \tanh \left( \frac{\tau}{2} \right) \right] \cdot \sinh \left( (N-m) \cdot \tau \right) \right) \times \left( \left( Z_g + Z_L \right) \cdot \cosh \left( N \cdot \tau \right) + \left( Z_c + Z_g \cdot Z_L \right) \cdot \sinh \left( N \cdot \tau \right) \right)^{-1}, \\
\frac{U_m'}{U_0} &= \left( \left( Z_L - Z_1 \right) \cdot \cosh \left( ((N-m) \cdot \tau \right) + \left[ Z_c - Z_L \cdot \tanh \left( \frac{\tau}{2} \right) \right] \cdot \sinh \left( (N-m) \cdot \tau \right) \right) \times \left( \left( Z_L \cdot \cosh \left( N \cdot \tau \right) + Z_c \cdot \sinh \left( N \cdot \tau \right) \right)^{-1}.
\end{align*}
\]

Consider now the particular selection of \( \{Z_g, Z_L\} \) to investigate the generation of (i) finite length, frequency-selecting ladders with various input and transfer immittances and voltage and current transmittances and (ii) specific ladder which can take the role of finite pulse delay line without pulse attenuation and with independently controlled pulse delay and rise times in Elmore’s sense [7], calculable in closed form. We will assume that impedances \( Z_g \) and \( Z_L \) are rational positive real functions in \( s \), so that they are realizable by passive transformerless RLC networks [17]. All network functions in (8) and (9) are real rational functions in \( s \), except

\[
\begin{align*}
\frac{U_n}{U_m} &= \left( Z_L \cdot \cosh \left( (N-n) \cdot \tau \right) + Z_L \cdot \sinh \left( (N-n) \cdot \tau \right) \right) \times \left( Z_L \cdot \cosh \left( N \cdot \tau \right) + Z_c \cdot \sinh \left( N \cdot \tau \right) \right)^{-1}.
\end{align*}
\]
Mathematical Problems in Engineering

\( U_n / I_n \), which must be rational, positive real function in \( s \), since it is the input immittance of RLC network.

**Case A (\( Z_g \)-arbitrary \( \land Z_L \rightarrow \infty [\Omega]\) (open-circuited ladder)).** From (8) and (9) it follows,

\[
\begin{align*}
I_n &= \frac{\sinh [(N - n) \cdot \tau]}{Z_c \cdot \cosh (N \cdot \tau) + Z_g \cdot \sinh (N \cdot \tau)}, \\
I_n / I_0 &= \frac{\sinh [(N - n) \cdot \tau]}{\sinh (N \cdot \tau)}, \\
U_n / E &= \frac{\cosh [(N - n) \cdot \tau]}{\cosh (N \cdot \tau) + (Z_g/Z_c) \cdot \sinh (N \cdot \tau)}, \\
U_n / U_0 &= \frac{\cosh [(N - n) \cdot \tau]}{\cosh (N \cdot \tau)}, \\
U_n / I_n &= \{\cotanh [(N - n) \cdot \tau]\} \cdot Z_c, \quad n = 0, N.
\end{align*}
\]

(10)

\[
U'_m / U_0 = \frac{\cosh [(N - m) \cdot \tau] - (Z_1/Z_c) \cdot \sinh [(N - m) \cdot \tau]}{\cosh (N \cdot \tau) + (Z_g/Z_c) \cdot \sinh (N \cdot \tau)},
\]

\[
U'_m / U_0 = \frac{\sinh [(N - m) \cdot \tau] - \sinh [(N - m - 1) \cdot \tau]}{\sinh (\tau) \cdot \cosh (N \cdot \tau)},
\]

(11)

**Case C (\( Z_g \)-arbitrary \( \land Z_L = 0 [\Omega]\) (short-circuited ladder)).** From (8) and (9) it is obtained,

\[
I_n = \frac{\cosh [(N - n) \cdot \tau]}{Z_2 \cdot \sinh [(N + 1) \cdot \tau]},
\]

\[
I_n / I_0 = \frac{\sinh [(N - n) \cdot \tau]}{\sinh (N \cdot \tau)}, \\
U_n / E = \frac{\cosh [(N - n) \cdot \tau] \cdot \sinh (\tau)}{\sinh [(N + 1) \cdot \tau]},
\]

(12)

\[
U_n / U_0 = \frac{\cosh [(N - n) \cdot \tau]}{\cosh (N \cdot \tau)}, \\
U_n / I_n = \{\cotanh [(N - n) \cdot \tau]\} \cdot Z_c, \quad n = 0, N,
\]

\[
U'_m / U_0 = \frac{2 \cdot \cosh [(N - m - (1/2)) \cdot \tau] \cdot \sinh (\tau/2)}{\sinh [(N + 1) \cdot \tau]},
\]

\[
= \frac{\sinh [(N - m) \cdot \tau] - \sinh [(N - m - 1) \cdot \tau]}{\sinh (\tau) \cdot \cosh (N \cdot \tau)},
\]

(13)

\[
\begin{align*}
I_n &= \frac{\cosh [(N - n) \cdot \tau]}{Z_L \cdot \cosh (N \cdot \tau) + Z_c \cdot \sinh (N \cdot \tau)}, \\
I_n / I_0 &= \frac{\cosh [(N - n) \cdot \tau]}{\cosh (N \cdot \tau)}, \\
U_n / E &= \frac{\sinh [(N - n) \cdot \tau]}{\sinh (N \cdot \tau) + (Z_g/Z_c) \cdot \cosh (N \cdot \tau)}, \\
U_n / U_0 &= \frac{\sinh [(N - n) \cdot \tau]}{\sinh (N \cdot \tau)}, \\
U_n / I_n &= \tanh [(N - n) \cdot \tau] \cdot Z_c, \quad n = 0, N,
\end{align*}
\]

(14)

\[
U'_m / E = \frac{Z_c \cdot \sinh [(N - m) \cdot \tau] - Z_1 \cdot \cosh [(N - m) \cdot \tau]}{Z_c \cdot \sinh (N \cdot \tau) + Z_g \cdot \cosh (N \cdot \tau)},
\]

\[
= \frac{\cosh [(N - m) \cdot \tau] - \cosh [(N - m - 1) \cdot \tau]}{\sinh (\tau) \cdot \left[\sinh (N \cdot \tau) + (Z_g/Z_c) \cdot \cosh (N \cdot \tau)\right]},
\]

(15)

Since we have \( \cosh(\tau) = 1 + Z_1/Z_2 \), then by Property 2 (Appendix A), \( U_n/U_0 \) \((n = 1, N)\) (10) can be easily converted into real rational function of \( Z_1/Z_2 \) or of \( s \). Similarly, by Property 3 (Appendix A), \( I_m/I_0 \) \((m = 1, N - 1)\) (10) can be, also, easily converted into real rational function of \( Z_1/Z_2 \) or of \( s \). When \( Z_1 \) and \( Z_2 \) are one-element-kind impedances, the zeros and poles of both \( U_n/U_0 \) and \( I_m/I_0 \) can be easily determined in the closed form. Since by Property 3 \( \sinh[(N - m) \cdot \tau] \) and \( \sinh[(N - m - 1) \cdot \tau] \) contain the same factor \( \sinh(\tau) \) \((m = 0, N - 1)\), then \( U'_m/U_0 \) \((m = 0, N - 1)\) (11) can be, also, easily converted into real rational function, either of \( Z_1/Z_2 \) or of the complex frequency \( s \).

**Case B (\( Z_g = Z_2 \cdot \cosh(\tau) = Z_1 + Z_2 \land Z_L \rightarrow \infty [\Omega]\)). In this case** (10) and (11) simplify to
\[
\frac{U'_m}{U_0} = \frac{\sinh [(N - m) \cdot \tau] - (Z_1/Z_c) \cdot \cosh [(N - m) \cdot \tau]}{\sinh (N \cdot \tau)},
\]

\[
\frac{U'_n}{U_0} = \frac{\cosh [(N - m) \cdot \tau] - \cosh [(N - m - 1) \cdot \tau]}{\sinh (\tau) \cdot \sinh (N \cdot \tau)},
\]

\[
m = 0, N - 1. \quad (15)
\]

According to Properties 2 and 3, respectively, \(I_k/I_0\) (\(n = 1, N\)) and \(U_m/U_0\) (\(m = 1, N - 1\)) (14) can be easily converted into real rational functions, either of \(Z_1/Z_2\) or of the complex frequency \(s\). If \(Z_1\) and \(Z_2\) are one-element-kind impedances, the zeros and poles of both \(I_k/I_0\) and \(U_m/U_0\) can be determined straightforwardly in closed form. Now, since \(Z_c \cdot \sinh (\tau)/Z_1 = 2 + Z_1/Z_2 \) and/or \((1 + Z_1/Z_2)^2 - \sinh^2 (\tau) = 1\), it can be seen from (15) that \(U'_m/U_0\) (\(m = 0, N - 1\)) is, also, convertible into real rational function, either of \(Z_1/Z_2\) or of the complex frequency \(s\), by using of both Properties 2 and 3.

Case D \((Z_g = Z_2 \cdot \cosh(\tau) = Z_1 + Z_2 \wedge \Lambda = 0 \; [\Omega])\). From (14) and (15) it readily follows that

\[
\frac{I_n}{E} = \frac{\cosh [(N - n) \cdot \tau]}{Z_2 \cdot \cosh [(N + 1) \cdot \tau]},
\]

\[
\frac{I_n}{I_0} = \frac{\cosh [(N - n) \cdot \tau]}{\cosh (N \cdot \tau)},
\]

\[
\frac{U_n}{E} = \frac{\sinh [(N - n) \cdot \tau] \cdot \sinh (\tau)}{\cosh (N + 1) \cdot \tau),
\]

\[
\frac{U_n}{U_0} = \frac{\sinh [(N - n) \cdot \tau]}{\sinh (N \cdot \tau)},
\]

\[
\frac{U'_n}{U_0} = \tanh [(N - n) \cdot \tau] \cdot Z_c, \quad n = 0, N,
\]

\[
\frac{U'_m}{E} = \frac{\cosh [(N - m) \cdot \tau] - \cosh [(N - m - 1) \cdot \tau]}{\cosh [(N + 1) \cdot \tau]},
\]

\[
\frac{U'_m}{U_0} = \frac{\cosh [(N - m) \cdot \tau] - \cosh [(N - m - 1) \cdot \tau]}{\sinh (\tau) \cdot \sinh (N \cdot \tau)},
\]

\[
m = 0, N - 1. \quad (17)
\]

By using of Properties 2 and 3 and \(\sinh^2 (\tau) = (1 + Z_1/Z_2)^2 - 1\), it can be seen from (16) and (17) that the network functions \(I_k/I_0\) (\(k = 1, N\)), \(U'_m/E\) (\(m = 0, N - 1\)), \(U'_n/U_0\) (\(n = 1, N - 1\)), \(U'_p/E\) (\(p = 0, N - 1\)), and \(U'_q/U_0\) (\(q = 0, N - 1\)) can be easily converted into real rational functions, either of \(Z_1/Z_2\) or of the complex frequency \(s\).

Case E \((Z_g = Z_L = Z_1)\). From (8) and (9), after using the relations \(Z_c = Z_2 \cdot \sinh (\tau), Z_1 = Z_c \cdot \tanh (\tau/2)\), and \(\cosh (\tau) = 1 + Z_1/Z_2\), it can be easily obtained that

\[
\frac{I_n}{E} = \frac{\cosh [(N - n) \cdot \tau]}{Z_c \cdot \sinh [(N - n) \cdot \tau]} + \frac{Z_1 \cdot \sinh [(N - n) \cdot \tau]}{\cosh [(N - n) \cdot \tau]}
\]

\[
\times \left[ \frac{2 \cdot Z_1 \cdot \cosh (N \cdot \tau)}{\cosh [(N + 1) \cdot \tau] - \sinh [(N - n) \cdot \tau]} \right]^{-1}
\]

\[
= \frac{\cosh [(N - n) \cdot \tau] + (Z_c/Z_1) \cdot \sinh [(N + 1) \cdot \tau]}{\cosh (N \cdot \tau) + (Z_1/Z_2) \cdot \sinh (N \cdot \tau)}
\]

\[
= \frac{\cosh [(N - n) \cdot \tau] + (Z_c/Z_1) \cdot \sinh [(N + 1) \cdot \tau]}{2 \cdot \cosh (N \cdot \tau) + [(Z_1/Z_2) / Z_1] \cdot \sinh (N \cdot \tau)}
\]

\[
= \sinh [(N - n) \cdot \tau] + \sinh [(N - n) \cdot \tau]
\]

\[
= \frac{\sinh [(N - n) \cdot \tau] + (Z_c/Z_1) \cdot \sinh [(N + 1) \cdot \tau]}{2 \cdot \sinh [(N + 1) \cdot \tau]}
\]

\[
\frac{U_n}{U_0} = \frac{\cosh [(N - n) \cdot \tau] + (Z_c/Z_1) \cdot \sinh [(N - n) \cdot \tau]}{\cosh [(N + 1) \cdot \tau] - \cosh (N \cdot \tau)}
\]

\[
\frac{U'_n}{U_0} = \frac{\cosh [(N - n) \cdot \tau] + (Z_c/Z_1) \cdot \sinh [(N - n) \cdot \tau]}{\sinh [(N - n) \cdot \tau] + (Z_c/Z_1) \cdot \cosh [(N - n) \cdot \tau]}
\]

\[
\cdot Z_c, \quad n = 0, N,
\]

\[
(18)
\]
$$U'_{m} = (\sinh [(N - m) \cdot \tau])$$

$$\times \left( \cosh (N \cdot \tau) \cdot \sinh (\tau) + \left(1 + \frac{Z_{1}}{Z_{2}}\right) \cdot \sinh (N \cdot \tau) \right)^{-1}$$

$$= \frac{\sinh [(N - m) \cdot \tau]}{\sinh [(N + 1) \cdot \tau]}.$$  

$$\frac{U'_{m}}{U_{0}} = (2 \cdot \sinh [(N - m) \cdot \tau])$$

$$\times \left( \cosh (N \cdot \tau) \cdot \sinh (\tau) + \left(2 + \frac{Z_{1}}{Z_{2}}\right) \cdot \sinh (N \cdot \tau) \right)^{-1}$$

$$= \frac{2 \cdot \sinh [(N - m) \cdot \tau]}{\sinh [(N + 1) \cdot \tau] + \sinh (N \cdot \tau)}, \quad m = 0, N - 1.$$  

Case $F (Z_{g} = Z_{L} = Z_{1} + 2 \cdot Z_{2}).$ From (8) and (9), after using relations $Z_{c} = Z_{2} \cdot \sinh(\tau), Z_{1} = Z_{c} \cdot \tanh(\tau/2), \cosh(\tau) = 1 + Z_{1}/Z_{2},$ and $Z_{c} \cdot \sinh(\tau)/(Z_{1} + 2Z_{2}) = Z_{1}/Z_{2},$ it readily follows that

$$I_{n} = \left( \cosh [(N - n) \cdot \tau] + \frac{Z_{1} + 2 \cdot Z_{2}}{Z_{c}} \cdot \sinh [(N - n) \cdot \tau] \right)$$

$$\times \left(2 \cdot (Z_{1} + 2 \cdot Z_{2}) \right) \cdot \frac{\cosh (N \cdot \tau) + \frac{Z_{1} + 2 \cdot Z_{2}}{Z_{c}} \cdot \sinh (N \cdot \tau)}{2 \cdot (Z_{1} + 2 \cdot Z_{2}) \cdot \sinh [(N + 1) \cdot \tau]}$$

$$\quad \left( \cosh (N \cdot \tau) + \frac{Z_{1} + 2 \cdot Z_{2}}{Z_{c}} \cdot \sinh (N \cdot \tau) \right)^{-1}$$

$$= \frac{\sinh [(N - n + 1) \cdot \tau] + \sinh [(N - n) \cdot \tau]}{2 \cdot \sinh [(N + 1) \cdot \tau] + \sinh (N \cdot \tau)}, \quad n = 0, N.$$  

$$\frac{I_{n}}{I_{0}} = \left( \cosh [(N - n) \cdot \tau] + \frac{Z_{1} + 2 \cdot Z_{2}}{Z_{c}} \cdot \sinh [(N - n) \cdot \tau] \right)$$

$$\times \left(2 \cdot \sinh [(N - n) \cdot \tau] + \frac{Z_{1} + 2 \cdot Z_{2}}{Z_{c}} \cdot \cosh (N \cdot \tau) \right)^{-1} \cdot Z_{c}$$

$$= \frac{\cosh [(N - n + 1) \cdot \tau] + \cosh [(N - n) \cdot \tau]}{\sinh [(N - n + 1) \cdot \tau] + \sinh [(N - n) \cdot \tau]} \cdot Z_{c}, \quad n = 0, N.$$  

$$\frac{U'_{n}}{U_{0}} = \left( \cosh [(N - m) \cdot \tau] \right)$$

$$\times \left( \frac{Z_{1}}{Z_{2}} + 2 \right) \cdot \frac{\cosh (N \cdot \tau) + \frac{Z_{1} + Z_{2}}{Z_{c}} \cdot \sinh (N \cdot \tau)}{[1 + \cosh (\tau)] \cdot \sinh [(N + 1) \cdot \tau]}.$$
\[
\begin{align*}
U'_m & \quad U_0 \\
& = \frac{2}{(Z_1/Z_2) + 2} \\
& \cdot \cosh [(N - m) \cdot \tau] \cdot \cosh (N \cdot \tau) + (Z_c/(Z_1 + 2 \cdot Z_2)) \cdot \sinh (N \cdot \tau) \\
& = \frac{2 \cdot \cosh [(N - m) \cdot \tau]}{\cosh ([N + 1] \cdot \tau + \cosh (N \cdot \tau)}.
\end{align*}
\] (21)

Case G \(Z_g = Z_L = Z_c = k \cdot Z_1 \) \((k > 1)\). From (7) it is easily obtained that
\[
Z_2 = (k^2 - 1)/2 \cdot Z_1, \quad \sinh(\tau) = 2 \cdot k/(k^2 - 1), \quad \cosh(\tau) = (k^2 + 1)/(k^2 - 1), \quad \exp(\tau) = (k + 1)/(k - 1), \quad \text{and} \quad \tanh(\tau/2) = 1/k.
\]
And from (8) and (9) it follows that
\[
\begin{align*}
I_n & \quad E \\
& = \frac{1}{2 \cdot k \cdot Z_1} \cdot \left(\frac{k - 1}{k + 1}\right)^n, \\
I_n & \quad Z_0 \\
& = \frac{U_n}{U_0} = \left(\frac{k - 1}{k + 1}\right)^n, \\
U_n & \quad E \\
& = \frac{1}{2} \cdot \left(\frac{k - 1}{k + 1}\right)^n, \\
U_n & \quad Z_c \\
& = Z_c \cdot Z_1, \quad n = 0, N, \\
U'_m & \quad E \\
& = \frac{k - 1}{2 \cdot k} \cdot \left(\frac{k - 1}{k + 1}\right)^m, \\
U'_m & \quad Z_c \\
& = \frac{k - 1}{k} \cdot \left(\frac{k - 1}{k + 1}\right)^m, \quad m = 0, N - 1.
\end{align*}
\] (22) (23)

From (22) and (23) it can be seen that even when \(E\) [with Laplace transform \(E = E(s)\)] is pulsed, the node and point voltages with respect to common-ground \(O\) (Figure 1) are reproduced faithfully and without delay but with geometrically progressive amplitude attenuation, regardless of the impedance \(Z_1\).

It is clear that relations (7)–(9) offer many other possibilities for the selection of \(Z_g, Z_L, Z_c, Z_2\) that lead to generation of versatile ladders realizing different types of frequency selective networks. An interesting one seems to be the common-ground \(RLC\) ladder realizing (a) pulse delay with independently selected Elmore’s delay and rise times and/or (b) true delay for either pulsed or analog frequency limited input signals. These topics will be considered in the following section.

3. Elmore’s Delay and Rise Times for Selected Types of Common-Ground, Uniform \(RLC\) Ladders

Consider the ladder in Figure 1 having \(Z_1 = R + L \cdot s, Y_2 = 1/Z_2 = G + C \cdot s\), and \(Z_g = Z_L = (L/C)^{1/2}\). Suppose that it holds the relation \(\alpha := R/L = G/C, similar\) to the one associated with per-unit-length parameters of distortionless transmission line [18, 19]. Let us define the auxiliary parameter \(\beta := 1/(L \cdot C)^{1/2}\), and let us recast the network voltage transmittances describing the transfer of emf \(E\) to the ladder points with voltages \(U_0, U_1, \ldots, U_N\) (Figure 1)—in the form suitable for calculating of Elmore’s delay and rise times [7] (Appendix B). Firstly, we should observe that the following holds:

\[
\begin{align*}
Z_1 & \quad Z_2 \\
& = \left(\frac{s + \alpha}{\beta}\right)^2, \\
Z_c & \quad Z_L \\
& = \frac{Z_c}{Z_L} \cdot \sinh(\tau) = \frac{s + \alpha}{\beta}, \\
\frac{1}{Z_g + Z_L} \cdot \left(Z_c + \frac{Z_g \cdot Z_L}{Z_c}\right) & \cdot \sinh(\tau) \\
& = \frac{s + \alpha}{2 \cdot \beta} \left[\left(\frac{s + \alpha}{\beta}\right)^2 + 3\right],
\end{align*}
\] (24)

and then by using (8) and the Properties 2 and 3, let us express the point voltage transmittances \(T_n(s) = U_n/E \) \((n = 0, N - 1)\) and \(T_N(s) = U_N/E\) in the following form:

\[
T_n(s) = \left(\frac{\beta^2}{2}\right)^n \cdot \left(\frac{(s + \alpha) \cdot \prod_{i=1}^{N-n} [(s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2\left(\frac{i \cdot \pi}{2 \cdot (N - n)}\right)]}{\beta \cdot \prod_{j=1}^{N-n} [(s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2\left(\frac{2 \cdot j - 1}{4 \cdot (N - n)} \cdot \pi\right)]}\right) \\
\times \left(\frac{(s + \alpha) \cdot [(s + \alpha)^2 + 3 \cdot \beta^2]}{\prod_{i=1}^{N-1} [(s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2\left(\frac{i \cdot \pi}{2 \cdot N}\right)]} + 2 \cdot \beta \right) \\
\cdot \left(\prod_{j=1}^{N} [(s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2\left(\frac{2 \cdot j - 1}{4 \cdot N} \cdot \pi\right)]\right)^{-1},
\]
\[ T_N(s) = \left( \frac{\beta^2}{2} \right)^N \cdot (2 \cdot \beta) \times \left( s + \alpha + [(s + \alpha)^2 + 3 \cdot \beta^2] \cdot \prod_{i=1}^{N-1} [(s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot N} \right)] + 2 \cdot \beta \cdot \prod_{j=1}^{N} [(s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{2 \cdot j - 1}{4 \cdot N} \cdot \pi \right)] \right)^{-1}. \]

(25)

As the calculation example of Elmore's times, let us suppose for this type of ladder that the specified parameters are \( N = 6 \), \( R = 50 \) [\( \Omega \)], \( L = 10 \) [mH], \( G = 5 \) [mS], and \( C = 1 \) [\( \mu \)F]. We firstly calculate \( Z_0 = Z_g = (L/C)^{1/2} = 100 \) [\( \Omega \)], \( \alpha = 5 \cdot 10^{-3} \) [1/s], and \( \beta = 10^4 \) [1/s], and then we recast \( T_n(s) = U_n/E \) \((n = 0, N - 1)\) and \( T_N(s) = U_N/E \) (25) in the following form:

\[ T_n(s) = \left( \frac{\beta^2}{2} \right)^n \cdot (A_0(N, n) + A_1(N, n) \cdot s + A_2(N, n) \cdot s^2 + \cdots + A_{2N-2n+1}(N, n) \cdot s^{2N-2n+1}) \]

\[ \times (B_0(N) + B_1(N) \cdot s + B_2(N) \cdot s^2 + \cdots + B_{2N+1}(N) \cdot s^{2N+1})^{-1}, \]

(26)

where all “A” and “B” coefficients are positive. To apply Elmore’s definitions of delay and rise times (Appendix B) for all points in the ladder with zero initial conditions (Figure 1) and excited at \( t = 0 \) with the step-voltage \( E \) with amplitude \( E \) [V], we must do the following.

(i) Firstly, check that the point voltages \( u_k = u_k(t) \) \((k = 0, N)\) have no overshoots, or eventually if they are present, overshoots must be less than 5\% of those voltages steady state values [7]. For example, if we have assumed for ladder with \( N = 6 \) sections that \( E = 10 \) [V], then its voltage step-responses \( u_k = u_k(t) \) \((k = 0, 6)\) and the node response \( u_0 \) as well, obtained through pspice simulation and depicted in Figures 2 and 3 in the interval \( t \in [0, 750] \) [\( \mu \)s], reveal that Elmore's definitions cannot be applied for responses \( u_0 \) and \( u_0 \), since the occurrence of overshoots, whereas for all other point voltages \( u_k = u_k(t) \) \((k = 1, 6)\), those definitions are applicable.

(ii) Secondly, calculate the coefficients \( A_0(N, n), A_1(N, n), A_2(N, n), B_0(N), B_1(N), \) and \( B_2(N), \) so as to determine the parameters \( a_1(N, n), a_2(N, n), b_1(N), \) and \( b_2(N) \) of the normalized transfer functions \( T_n(s)/T_0(0) \) \((n = 0, N - 1)\) and \( T_N(s)/T_N(0) \) obtained from (26) according to the relations

\[ \frac{T_n(s)}{T_n(0)} = \left( 1 + a_1(N, n) \cdot s + a_2(N, n) \cdot s^2 + \cdots + a_{2N-2n+1}(N, n) \cdot s^{2N-2n+1} \right) \]

\[ \times \left( 1 + b_1(N) \cdot s + b_2(N) \cdot s^2 + \cdots + b_{2N+1}(N) \cdot s^{2N+1} \right)^{-1}, \]

\[ T_n(0) = \left( \frac{\beta^2}{2} \right)^n \cdot \frac{A_0(N, n)}{B_0(N)}. \]

\(^1\) The times calculated according to Elmore’s definitions.
\(^2\) The times obtained through PSpice simulation according to the classical definitions of \(T_{dx}\) (“50%” delay time) and \(T_{re}\) (“10%–90%” rise time).
\(^3\) All data are related to the ladder with zero initial conditions.

For RLC ladder having \(N = 6\), \(R = 50\) [Ω], \(L = 10\) [mH], \(G = 5\) [mS], \(C = 1\) [μF]—excited at \(t = 0\) by step emf \(e\) with amplitude \(E = 10\) [V], the obtained results are summarized in Table 1.

Another interesting ladder in Figure 1 is the one with \(Z_1 = R + L \cdot s, Y_2 = 1/Z_2 = G + C \cdot s, Z_g = 0[Ω], Z_L = (L/C)^{1/2}\), and \(\alpha := R/L = G/C\). Again, let it be \(\beta := 1/(L \cdot C)^{1/2}\). By using (8) and Properties 2 and 3, the point voltage transmittances \(T_n(s) = U_n/E\) \((n = 0, N - 1)\) and \(T_N(s) = U_N/E\) are obtained as follows:

\[
T_n (s) = \left( \frac{\beta^2}{2} \right)^n 
\cdot \left( s + \alpha \right) \cdot \prod_{i=1}^{N-n} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot (N - n)} \right) \right)
\cdot B_0 (N)
\cdot \prod_{i=1}^{N} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{2 \cdot j - 1}{4 \cdot (N - n)} \cdot \pi \right) \right)
\times \prod_{i=1}^{N} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot N} \right) \right)
\]

For any given set of input parameters \(N, n, R, L, C, G\), provided that the condition \(R/L = G/C\) is satisfied.

(iii) Calculate Elmore’s delay time \(T_D(n)\) and rise time \(T_R(n)\) of any point step-voltage response having no overshoot, according to definitions (B.5) in Appendix B and by using (27)

\[
T_D (N, n) = b_1 (N) - a_1 (N, n),
\]

\[
T_R (N, n)
= \sqrt{2 \cdot \pi \cdot [b_2^2 (N) - a_2^2 (N, n) + 2 \cdot [a_2 (N, n) - b_2 (N)]]},
\]

Calculation of coefficients \(A_0(N, n), A_1(N, n), A_2(N, n), B_0(N), B_1(N), B_2(N), a_1 (N, n), a_2 (N, n), b_1 (N), b_2 (N),\) and Elmore’s times, for any given set of input parameters \(N, n, R, L, C, G\), provided that the condition \(R/L = G/C\) is satisfied.

\[
t_{\mu}(\infty) = A_0(N, n),
\]

\[
t_{\mu}(s) = \left( \frac{\beta^2}{2} \right)^n 
\cdot \left( s + \alpha \right) \cdot \prod_{i=1}^{N-n} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot (N - n)} \right) \right)
\cdot B_0 (N)
\cdot \prod_{i=1}^{N} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{2 \cdot j - 1}{4 \cdot (N - n)} \cdot \pi \right) \right)
\times \prod_{i=1}^{N} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot N} \right) \right)
\]

Another interesting ladder in Figure 1 is the one with \(Z_1 = R + L \cdot s, Y_2 = 1/Z_2 = G + C \cdot s, Z_g = 0[Ω], Z_L = (L/C)^{1/2}\), and \(\alpha := R/L = G/C\). Again, let it be \(\beta := 1/(L \cdot C)^{1/2}\). By using (8) and Properties 2 and 3, the point voltage transmittances \(T_n(s) = U_n/E\) \((n = 0, N - 1)\) and \(T_N(s) = U_N/E\) are obtained as follows:

\[
T_n (s) = \left( \frac{\beta^2}{2} \right)^n 
\cdot \left( s + \alpha \right) \cdot \prod_{i=1}^{N-n} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot (N - n)} \right) \right)
\cdot B_0 (N)
\cdot \prod_{i=1}^{N} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{2 \cdot j - 1}{4 \cdot (N - n)} \cdot \pi \right) \right)
\times \prod_{i=1}^{N} \left( (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot N} \right) \right)
\]
\[ T_N(s) = \left( \frac{\beta^2}{2} \right)^N \cdot (2 \cdot \beta^2) \]
\[ \times \left( (s + \alpha) \cdot \prod_{i=1}^{N} \left[ (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{i \cdot \pi}{2 \cdot N} \right) \right] \right) \]
\[ + \beta \cdot \prod_{j=1}^{N} \left[ (s + \alpha)^2 + 2 \cdot \beta^2 \cdot \sin^2 \left( \frac{2 \cdot j - 1}{4 \cdot N} \cdot \pi \right) \right]^{-1}. \]  

(29)

In this case, Elmore’s delay and rise times can be calculated in the similar way as it has been done in (25). The specified set of parameters \( [R, L, C, G, N, n] \) provided that the voltages of selected ladder points and/or nodes satisfy the condition (i), Elmore’s times can be calculated by using (26)–(29), but further consideration of this point will be left to the reader.

Also, an interesting ladder is the one with \( Z_1 = R/2, Z_2 = 1/Z_2 = C \cdot s, Z_g = 0 \) [11], and \( Z_L \to \infty \) [\( \Omega \)] (Figure 1), which resembles to a delay line [13], but it does not truly behave like it and rather may be used for generation of delayed time markers with Elmore’s times expressible in the closed form. To see this, let us produce the point voltage transmittances \( T_n(s) = U_n(s)/E \) \((n = 0, N)\) and the node voltage transmittances \( T_m'(s) = U_m'(s)/E \) \((m = 0, N - 1)\), by using (8), (9), and Property 2 or Case A (10):

\[ \cdot \left( \prod_{i=1}^{N-n} \left[ s + \frac{4}{R \cdot C} \cdot \sin^2 \left( \frac{2 \cdot i - 1}{4 \cdot (N-n)} \cdot \pi \right) \right] \right) \]
\[ \cdot \left( \prod_{j=1}^{n} \left[ s + \frac{4}{R \cdot C} \cdot \sin^2 \left( \frac{2 \cdot j - 1}{4 \cdot N} \cdot \pi \right) \right] \right)^{-1}. \]  

(30)

Observe that if \( s \to 0 \), then also \( \tau \to 0 \), and from (30) and (31) it follows that \( U_n/E \to 1 \) \((n = 1, N)\) and \( U_m'/E \to 1 \) \((m = 0, N - 1)\). This is in obvious physical agreement with the network behaviour in DC operating regime. The previous conclusions could be, also, formally verified by using Remark 1 (Appendix A) in calculation of \( T_n(n = 1, N) \) and \( T_m'(m = 0, N - 1) \) for \( s = 0 \). If excitation \( e(t) \) of the network with zero initial conditions is step voltage at \( t = 0 \) with amplitude \( E \), then \( E = E(s) = \mathcal{Z}[e(t)] = E/s \). From (30), (31), and Remark 1 we can, also, easily see that \( u_k(0) = \lim_{\tau \to \infty} [E \cdot T_k(s)] = 0 \) \([V] \) and \( u_k(\infty) = \lim_{\tau \to 0} [E \cdot T_k(s)] = E \) \([V] \) \((k = 1, N)\). In this case it can be shown that (i) the node and the point voltages are strictly monotone in \( t \) [11], so that Elmore’s definitions can be applied leading to (ii) closed-form expressions of delay and rise times for node voltages [15]. To illustrate the point (i) let us consider the network in Figure 4 whereon capacitance voltages are denoted with \( x_i = x_i(t) \) \((i = 1, N)\). Let us introduce notation \( \chi := t/R \cdot C, x_1 := \xi(\chi), x(t) := [x_1(t), x_2(t) \cdots x_N(t)]^T, \xi(\chi) = [\xi_1(\chi) \xi_2(\chi) \cdots \xi_N(\chi)]^T \) (”\( T \)” operation of matrix transposition), and \( e(t) = \epsilon(\chi) \).

For the ladder in Figure 4 the following system of state-space equations can be written in \( \chi \)-domain:

\[ \frac{d\xi(\chi)}{d\chi} = A \cdot \xi(\chi) + B \cdot \epsilon(\chi), \]  

(32)

\[ A := \begin{bmatrix} -3 & 1 & 0 & \cdots & 0 \\ 1 & -2 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 & -2 \\ 0 & 0 & \cdots & 0 & 1 \end{bmatrix}, \]  

\[ B := [2 \ 0 \ \cdots \ 0]^T \] \((N \times 1 \) column vector), \( \xi(0) = [0 \ 0 \ \cdots \ 0]^T \) \([V] \) \((N \times 1 \) column vector of state initial conditions)\).

Since the real symmetric \( N \times N \) regular tridiagonal matrix \( A \) is hyperdominant [17], then it is also positive definite and both similar and congruent to diagonal matrix \( D = \text{diag}(d_1, d_2, \ldots, d_N) \) [20], where \( d_i > 0 \) \((i = 1, N)\). So, there exists an orthogonal matrix \( Q \) [20], such that \( -Q^{-1} \cdot A \cdot Q = -Q^{-1} \cdot D \cdot Q = D \). If we introduce the coordinate transformation \( \xi(\chi) = Q \cdot \xi(\chi) \), then the vector differential equation in \( \xi(\chi) = [\xi_1(\chi) \xi_2(\chi) \cdots \xi_N(\chi)] \) (32) takes on the following coordinate decoupled form:
\[
\frac{d\xi(\chi)}{d\chi} = Q^{-1} \cdot A \cdot \xi(\chi) + Q^{-1} \cdot B \cdot \varepsilon(\chi)
\]
\[
= -D \cdot \xi(\chi) + Q^{-1} \cdot B \cdot \varepsilon(\chi),
\]
(33)

\[\xi(0) = [0 \ 0 \ \cdots \ 0]^T \quad (N \times 1 \ \text{column vector of the "transformed" state-space initial conditions}).\]

For \( N = 8 \), the matrices \( Q \) and \( D \) with entries rounded up to 3 decimal places are being obtained as

\[
Q = 
\begin{bmatrix}
-0.497 & 0.478 & -0.441 & 0.386 & -0.317 & 0.235 & -0.145 & 0.049 \\
0.478 & -0.317 & 0.049 & 0.235 & -0.441 & 0.497 & -0.386 & 0.145 \\
-0.441 & 0.049 & 0.386 & -0.478 & 0.145 & 0.317 & -0.497 & 0.235 \\
0.386 & 0.235 & -0.478 & -0.049 & 0.497 & -0.145 & -0.441 & 0.317 \\
-0.317 & -0.441 & 0.145 & 0.497 & -0.049 & -0.478 & -0.497 & 0.235 \\
0.235 & 0.497 & 0.317 & -0.145 & -0.478 & -0.386 & 0.049 & 0.441 \\
-0.145 & -0.386 & -0.497 & -0.441 & 0.235 & -0.478 & 0.049 & 0.317 \\
0.049 & 0.145 & 0.235 & 0.317 & 0.386 & 0.441 & 0.411 & 0.478
\end{bmatrix},
\]
(34)

\[
D = 
\begin{bmatrix}
3.961 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 3.663 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 3.111 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 2.390 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1.610 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0.888 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0.337 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0.038
\end{bmatrix}.
\]
(35)

Now, if we suppose that the excitation \( e(t) = \varepsilon(\chi) \) is the step voltage at \( t = 0 \) with amplitude \( E = 1 [V] \), then the unique solution of the vector differential equation (32) is produced in following form:

\[
\xi(\chi) = Q \cdot Q^{-1} \cdot B, \quad \text{wherefrom (as it was expected)} \quad \text{we obtain that}
\]
\[
x(\infty) = \xi(\infty) = -A^{-1} \cdot B
\]
\[ u_2(\chi) = 1 + 0.005 \cdot e^{-3.961\chi} + 0.035 \cdot e^{-3.363\chi} + 0.061 \cdot e^{-3.311\chi} + 0.039 \cdot e^{-2.390\chi} - 0.0584 \cdot e^{-1.610\chi} - 0.216 \cdot e^{-0.888\chi} - 0.380 \cdot e^{-0.337\chi} - 0.370 \cdot e^{-0.038\chi}, \]
\[ u_3(\chi) = 1 - 0.006 \cdot e^{-3.961\chi} - 0.0372 \cdot e^{-3.363\chi} - 0.013 \cdot e^{-3.311\chi} + 0.085 \cdot e^{-2.390\chi} + 0.0572 \cdot e^{-1.610\chi} - 0.168 \cdot e^{-0.888\chi} - 0.428 \cdot e^{-0.337\chi} - 0.601 \cdot e^{-0.038\chi}, \]
\[ u_4(\chi) = 1 + 0.009 \cdot e^{-3.961\chi} + 0.026 \cdot e^{-3.363\chi} - 0.047 \cdot e^{-3.311\chi} - 0.072 \cdot e^{-2.390\chi} + 0.107 \cdot e^{-1.610\chi} + 0.165 \cdot e^{-0.888\chi} - 0.291 \cdot e^{-0.337\chi} - 0.897 \cdot e^{-0.038\chi}, \]
\[ u_5(\chi) = 1 - 0.0780 \cdot e^{-3.961\chi} + 0.115 \cdot e^{-3.363\chi} + 0.041 \cdot e^{-3.311\chi} - 0.160 \cdot e^{-2.390\chi} + 0.0193 \cdot e^{-1.610\chi} + 0.253 \cdot e^{-0.888\chi} - 0.203 \cdot e^{-0.337\chi} - 0.986 \cdot e^{-0.038\chi}, \]
\[ u_6(\chi) = 1 + 0.011 \cdot e^{-3.961\chi} - 0.011 \cdot e^{-3.363\chi} - 0.026 \cdot e^{-3.311\chi} + 0.094 \cdot e^{-2.390\chi} - 0.140 \cdot e^{-1.610\chi} + 0.089 \cdot e^{-0.888\chi} + 0.157 \cdot e^{-0.337\chi} - 1.172 \cdot e^{-0.038\chi}, \]
\[ u_7(\chi) = 1 - 0.012 \cdot e^{-3.961\chi} + 0.031 \cdot e^{-3.363\chi} - 0.037 \cdot e^{-3.311\chi} + 0.020 \cdot e^{-2.390\chi} + 0.029 \cdot e^{-1.610\chi} - 0.130 \cdot e^{-0.888\chi} + 0.342 \cdot e^{-0.337\chi} - 1.245 \cdot e^{-0.038\chi}, \]
\[ u_8(\chi) = 71 + 0.012 \cdot e^{-3.961\chi} - 0.0380 \cdot e^{-3.363\chi} + 0.067 \cdot e^{-3.311\chi} - 0.102 \cdot e^{-2.390\chi} + 0.152 \cdot e^{-1.610\chi} - 0.234 \cdot e^{-0.888\chi} + 0.412 \cdot e^{-0.337\chi} - 1.270 \cdot e^{-0.038\chi}. \]
The coefficients $a_1(N,n)$, $a_2(N,n)$, $b_1(N)$, and $b_2(N)$ (27) necessary for calculation of $T_D(N,n)$ and $T_R(N,n)$ according to Elmore's definitions (28) are obtained for $T_n(s)$ ($n = 1, N$) (38) in the following form (see Corollary 3 in Appendix A):

$$a_1(N, n) = \frac{1}{\Omega_0} \cdot \sum_{i=1}^{N-n} \frac{1}{\sin^2 \left( \frac{((2 \cdot i - 1) / (4 \cdot N)) \cdot \pi}{\Omega_0} \right)} = \frac{R \cdot C}{2} \cdot (N - n)^2,$$

$$b_1(N) = \frac{1}{\Omega_0} \cdot \sum_{j=1}^{N} \frac{1}{\sin^2 \left( \frac{(2 \cdot j - 1) / (4 \cdot N)}{\pi} \right)} = R \cdot C \cdot N^2,$$

and

$$a_2(N, n) = \frac{1}{2 \cdot \Omega_0^2} \cdot \left[ \sum_{i=1}^{N-n} \frac{1}{\sin^2 \left( \frac{((2 \cdot i - 1) / (4 \cdot N-n)) \cdot \pi}{\Omega_0} \right)} ight]^2$$

$$- \sum_{i=1}^{N-n} \frac{1}{\sin^4 \left( \frac{((2 \cdot i - 1) / (4 \cdot N-n)) \cdot \pi}{\Omega_0} \right)} = (R \cdot C)^2 \cdot (N-n)^2 \cdot \left[ (N-n)^2 - 1 \right],$$

$$b_2(N) = \frac{1}{2 \cdot \Omega_0^2} \cdot \left[ \sum_{i=1}^{N} \frac{1}{\sin^2 \left( \frac{(2 \cdot i - 1) / (4 \cdot N)}{\pi} \right)} ight]^2$$

$$- \sum_{i=1}^{N} \frac{1}{\sin^4 \left( \frac{(2 \cdot i - 1) / (4 \cdot N)}{\pi} \right)} = (R \cdot C)^2 \cdot N^2 \cdot (N^2 - 1),$$

provided that $a_1(N, N) = a_2(N, N) = 0$, and finally, Elmore's delay and rise times for point voltages $u_n (n = 1, N)$ (Figure 4) are calculated in the closed form according to the relations

$$T_D(N,n) = b_1(N) - a_1(N,n) = \frac{R \cdot C}{2} \cdot \left[ N^2 - (N-n)^2 \right],$$

$$T_R(N,n) = \sqrt{2 \cdot \pi \cdot [b_2^2(N) - a_2^2(N,n) + 2 \cdot [a_2(N,n) - b_2(N)]]} = R \cdot C \cdot \sqrt{\frac{\pi}{6}} \cdot \sqrt{[N^2 - (N-n)^2] \cdot \left[ 2 \cdot \left[ N^2 + (N-n)^2 \right] + 1 \right]},$$

The coefficients $a_1(N,n), a_2(N,n), b_1(N), b_2(N)$ (27) necessary for calculation of $T_D(N,n)$ and $T_R(N,n)$ according to Elmore's definitions (28) are obtained for $T_n(s)$ ($n = 1, N$) (38) in the following form (see Corollary 3 in Appendix A):

$$T_N(s) = (1) \times \left( \prod_{j=1}^{N} \left[ 1 + \frac{s}{\Omega_0} \cdot \sin^2 \left( \frac{((2 \cdot j - 1) / (4 \cdot N)) \cdot \pi}{\Omega_0} \right) \right] \right)^{-1},$$

$$T_m' (s) = \frac{T_m + T_{m+1}}{2 \cdot (1 + (s/\Omega_0))}, \quad m = 0, N-1.$$

(39)
whereas Elmore’s delay times $T'_D(N, m)$ and rise times $T'_R(N, m)$ for node voltages $u'_m(m = 0, N - 1)$ (Figure 1) are calculated by using (38) and (39):

$$T'_D(N, m) = b'_1(N) - a'_1(N, m),$$

$$T'_R(N, m) = \sqrt{2 \cdot \pi \cdot [b'^2_1(N) - a'^2_1(N, m) + 2 \cdot \{a'_2(N, m) - b'_2(N)\}]} ,$$

(45)

where

$$a'_1(N, m) = \frac{R \cdot C}{4} \cdot [(N - m)^2 + (N - m - 1)^2],$$

$$b'_1(N) = \frac{1}{\Omega_0} \cdot \left[1 + \sum_{j=1}^{N} \frac{1}{\sin^2 \left((2 \cdot j - 1) / (4 \cdot N) \right) \cdot \pi}\right],$$

(46)

$$a'_2(N, m) = \frac{(R \cdot C)^2}{48} \times \left[ (N - m)^2 \cdot \left[ (N - m)^2 - 1 \right] + (N - m - 1)^2 \cdot \left[ (N - m - 1)^2 - 1 \right] \right],$$

(47)

$$b'_2(N) = \frac{1}{2 \cdot \Omega_0^2} \cdot \left[1 + \sum_{i=1}^{N} \frac{1}{\sin^2 \left( (2 \cdot i - 1) / (4 \cdot N) \right) \cdot \pi}\right]^2$$

$$- 1 - \sum_{i=1}^{N} \frac{1}{\sin^2 \left((2 \cdot i - 1) / (4 \cdot N) \right) \cdot \pi},$$

$$= \frac{(R \cdot C)^2}{24} \cdot N^2 \cdot (N^2 + 2).$$

(48)

From (43) it follows that $T'_D(N, N) \propto N^2$ and from (44) that $T'_R(N, m) > 2 \cdot T'_D(N, n)$ ($n = \frac{1}{2}, N$), which does not qualify this type of ladder for using as pulse delay line in its own right. If in the ladder on Figure 4 $N = 6$, $R = 50 \, \Omega$, and $C = 2 \, [\text{nF}]$, and excitation $e(t)$ is periodic pulse train with amplitude 10 $[\text{V}]$, period $T = 100 \, [\mu\text{s}]$, and duty-cycle 50%.

Finally, consider that the ladder in Figure 8 is analogue to the ladder in Figure 1. Assume $\alpha = R/L = 1/(R \cdot C)$ and

$$Z_g = Z_1 = \frac{1}{2} \cdot \frac{R \cdot L \cdot s}{R + L \cdot s} = \frac{R}{2} \cdot \frac{s}{s + \alpha},$$

$$Z_2 = \frac{1}{C \cdot s},$$

$$Z_L = Z_1 + \frac{1}{1 + R \cdot C \cdot s} = \frac{R}{2} \cdot \frac{s + 2\alpha}{s + \alpha} \cdot (Z_g + Z_L = R).$$

(49)

In this case, from (7) we obtain

$$Z_c = \sqrt{Z_1 \cdot (Z_1 + 2 \cdot Z_2)} = \frac{R}{2} \cdot \frac{s + 2\alpha}{s + \alpha} = Z_L,$$

$$\sinh(t) = \frac{Z_c}{Z_2} \cdot \frac{Z_1}{Z_2} \cdot \frac{s + 2\alpha}{2\alpha \cdot (s + \alpha)},$$

$$\cosh(t) = 1 + \frac{Z_1}{Z_2} \cdot \frac{(s + \alpha)^2 + \alpha^2}{2\alpha \cdot (s + \alpha)}.$$  

(50)
From (50) it is found that \( e^{-\tau} = \alpha/(s + \alpha) \), and from (9) it follows that

\[
T_m'(s) = \frac{U_m'}{E} = \frac{Z_{m-1} - Z_1}{Z_{m-1} + Z_1} \cdot e^{-m\tau}
\]

\[
= \frac{\alpha}{s + \alpha} \cdot e^{-m\tau} = \left( \frac{\alpha}{s + \alpha} \right)^{m+1} \tag{51}
\]

\[
T_m(s) = \frac{U_m}{E} = \frac{U}{U_{N-2}} = \frac{1}{(1 + (s/\alpha))^{N-1}} \cdot \frac{\alpha}{s + \alpha} = \frac{1}{(1 + (s/\alpha))^{N}}. \tag{52}
\]

Relation (52) could have been produced in a less formal way by observing that the ladder in Figure 8 is a constant resistance network when \( R/L = 1/(R \cdot C) \), since the input impedances (denoted by dashed arrows) seen from the pertinent pairs of nodes are all equal to \( R \). If the ladder has no initial conditions and if it is excited by unit-step voltage \( e(t) \) at \( t = 0 \) \( E = E(s) = \mathcal{L}[e(t)] = 1/s \), then for overall step response \( u(t) = \mathcal{L}^{-1}[U(s)] \) it holds that (a) \( u(0) = \lim_{s \to \infty} s \cdot U(s) = 0 \), (b) \( u(\infty) = \lim_{s \to 0} s \cdot U(s) = 1 \), and (c) \( u(t) \) is a monotone increasing function in \( t \) (i.e., \( u(t) \) has no overshoots) since we have

\[
0 \leq u(t) = \mathcal{L}^{-1} \left[ \left( \frac{\alpha}{s + \alpha} \right)^N \cdot \frac{1}{s} \right] = 1 - e^{-\alpha t} \cdot \sum_{k=0}^{N-1} \left( \frac{\alpha}{s + \alpha} \right)^k \leq 1, \tag{53}
\]

\[
\frac{du(t)}{dt} = \frac{\alpha^N \cdot e^{-\alpha t} \cdot t^{N-1}}{(N-1)!} > 0, \quad t \geq 0. \]

From (52) we obtain the “a” and “b” coefficients necessary for calculation of Elmore’s delay time \( T_D \) and rise time \( T_R \) (B.5) for the network in Figure 8:

\[
a_1 = a_2 = 0,
\]

\[
b_1 = \frac{N}{\alpha}, \quad b_2 = \frac{N \cdot (N-1)}{2 \cdot \alpha^2},
\]

\[
T_D = \frac{N}{\alpha} = \frac{L}{R} \cdot N = N \cdot \sqrt{L \cdot C},
\]

\[
T_R = \frac{1}{\alpha} \cdot \sqrt{2\pi \cdot N} = \frac{1}{\alpha} \cdot \sqrt{2\pi \cdot N \cdot L \cdot C}. \tag{54}
\]

The procedure for determining the ladder parameters when both Elmore’s times \( T_D \) and \( T_R \) are specified consists of the following three steps: (a) firstly, we calculate \( N = \text{ant}(2\pi \cdot (T_D/T_R)^2 + 1) \), and then from (54) we calculate the actual rise time \( T_{\text{rise}} = T_D \cdot \left(2\pi/(N)\right)^{1/2} < T_R \) (\( T_D \) remains unchanged), (b) assume \( C \), and (c) calculate \( R = (T_D/N)/C \) and \( L = (T_D/N)^2/C \). When solely Elmore’s delay time \( T_D \) is specified and \( T_R \) is left unspecified, we arbitrarily select some reasonably great \( N \), so as to produce the sufficiently small \( T_R \) of the output \( u \) for the unit-step input and then follow the steps (b) and (c).

But in the case when \( N \) is small and we want to realize Elmore’s delay time \( T_D \) for pulse train with period \( T \) and duty cycle \( \delta \), it can be shown that one of the following two conditions must be satisfied, in order to prevent severe distortion of transmitted “pulses”: (i) \( T_D \leq (1 - \delta) \cdot T/2 \), when \( \delta \geq 1/2 \), or (ii) \( T_D \leq \delta \cdot T/2 \), when \( \delta < 1/2 \). For the ladder in Figure 8 with \( N = 20, R = 10 \) [\( \Omega \)], \( L = 0.5 \) [\( \mu \text{H} \)], and \( C = 5 \) [\( \mu \text{F} \)], excited by pulse train \( e(t) \) with amplitude 10 [\( \text{V} \)], period \( T = 10 \) [\( \text{ms} \)], and duty-cycle \( \delta = 0.6 \), by ladder in Figure 8 with \( N = 20, R = 10 \) [\( \Omega \)], \( L = 0.5 \) [\( \mu \text{H} \)], and \( C = 5 \) [\( \mu \text{F} \)], the obtained results of \texttt{pspice} simulation in the time interval \( t \in [0, 20] \) [\( \text{ms} \)] are depicted in Figure 9, wherein are plotted the excitation \( e(t) \), voltage \( u_9(t) \) of the 10th capacitor, and the voltage \( u(t) \) of the 20th capacitor. Elmore’s delay and rise times for voltage \( u_{m-1}' \) of the \( m \)th capacitor \( (m = 1, N-1) \) (Figure 8) are, respectively, \( m \cdot \sqrt{L \cdot C} \) and \( \sqrt{2\pi \cdot m \cdot L \cdot C} \), according to (54). For example, Elmore’s delay time of \( u_9'(t) \) is \( 10 \cdot \sqrt{L \cdot C} = 0.5 \) [\( \text{ms} \)] and of \( u(t) \) is \( 20 \cdot \sqrt{L \cdot C} = 1 \) [\( \text{ms} \)]. Both these values are slightly different from those obtained according to the classical definition of delay time and they are denoted in Figure 9 for comparison. In this case, Elmore’s rise time for \( u \) obtained from (54) is \( T_{\text{rise}} = \sqrt{\pi/10} \) [\( \text{ms} \)] = 560.5 [\( \mu \text{ms} \)], whereas the classical rise time obtained from Figure 9 is slightly different, \( T_{\text{rise}} = 568.9[\mu \text{ms}] \).

Consider now the same ladder excited by the pulse train \( e(t) \) with amplitude 10 [\( \text{V} \)], provided that the condition (i) is violated by supposing that \( T = 2 \) [\( \text{ms} \)] and \( \delta = 0.6 \). The results of \texttt{pspice} simulation in the time interval \( t \in [0, 5] \) [\( \text{ms} \)] are depicted in Figure 10 and obviously exhibit a severe distortion of “pulses” \( u \) being transmitted to the end of the ladder.

![Figure 9: Realization of Elmore’s delay time](image-url)
Consider again the same ladder excited by the pulse train $e(t)$ with amplitude $10$ [V], provided that condition (ii) is violated by supposing that $T = 2$ [ms] and $\delta = 0.4$. The results of pspice simulation are depicted in Figure II in the time interval $t \in [0, 5]$ [ms] and obviously exhibit a severe distortion of “pulses” $u(t)$ being transmitted to the end of the ladder.

And finally, consider the ladder in Figure 8 which should realize Elmore’s delay time $T_D = 5$ [ms] and rise time $T_R = 560.5$ [$\mu$s]. Let the excitation $e(t)$ be the pulse-train with amplitude $10$ [V], period $T = 20$ [ms], and duty-cycle $\delta = 0.5$. To avoid a severe distortion of output pulses $u(t)$, it is sufficient to follow the previously formulated steps (a) + (c). So, according to the step (a) we firstly calculate $N = 500$. Then, in the step (b) we assume that, say, $C = 1$ [$\mu$F] and finally in the step (c) we calculate $R = 10$ [$\Omega$] and $C = 1 [\muF]$. The time variations of $e(t)$ and $u(t)$ obtained by pspice simulation are depicted in Figure 12 in the time interval $t \in [0, 40]$ [ms]. Therefrom, we find the classical delay and rise times of the output voltage $u(t)$, $T_D \approx 5$ [ms] and $T_R \approx 575$ [$\mu$s], respectively. Both these times are slightly different from the pertinent Elmore’s times (54), whose obvious advantage is that are explicitly calculable as functions of $\{N, R, L, C\}$ parameters of common-ground, uniform RLC ladder (Figure 8).

In the previous examples, we have investigated Elmore’s times of voltages at points and/or nodes in several characteristic types of common-ground uniform RLC ladders excited, either by step or by pulse-train emfs. In the most general case, consider the realization of physical delay time $T_D$ for arbitrary excitation $e(t)$ (i.e., true delay time), by using the RLC ladder in Figure 8 (true delay line). If we presume for this network that $N \to \infty$, then from (52) and (54) it readily follows that

$$\lim_{N \to \infty} T(s) = \lim_{N \to \infty} \frac{1}{(1 + (s/\alpha))^N}$$

$$= \lim_{N \to \infty} \left(1 + \frac{s \cdot T_D}{N}\right)^{N(\alpha \cdot T_D)} = e^{-s \cdot T_D},$$

so that the overall network response becomes $u(t) = \mathcal{L}^{-1}[U(s)] = \mathcal{L}^{-1}[e^{-s \cdot T_D} \cdot E(s)] = e(t - T_D)$ (i.e., $u(t)$ is the exact replica of the excitation $e(t)$ delayed by the time $T_D$). Let us firstly introduce the notation

$$z := \frac{s \cdot T_D}{N} = (\sigma + j \cdot \omega) \cdot \frac{T_D}{N}$$

$$= \frac{\sigma \cdot T_D}{N} + j \cdot \frac{\omega \cdot T_D}{N},$$

$$\text{Re} \{z\} := \frac{\sigma \cdot T_D}{N},$$

$$\text{Im} \{z\} := \frac{\omega \cdot T_D}{N}.$$
we have 

$$f(z) := (1 + z)^{1/z}$$

and then investigate the conditions under which the function $f(z)$ becomes close to the number $e$. It is obvious from (55) that these conditions relate to certain restrictions in the span of $N$, $\sigma$, and $\omega$. Observe that $f(z) \to e$ when $z \to 0$. After some manipulation, from (56) we easily obtain

$$|f(z)| = e^{\Im\{z\}/(2\Re\{z\} + \Im\{z\})} \cdot \alpha \tan(\Im\{z\}/(1 + \Re\{z\}))$$

$$\cdot \left(1 + \Re\{z\}\right)^2 + \Im^2\{z\}\right)\right)^{\Re\{z\}/(2\Re\{z\} + \Im^2\{z\})}$$

$$\cdot \alpha \tan\left[\frac{\Im\{z\}}{1 + \Re\{z\}}\right] \cdot \frac{\Re\{z\}}{\Re^2\{z\} + \Im^2\{z\}}$$

where $\arg(f(z))$ is expressed in radians and should be multiplied by $180/\pi$ to be expressed in [deg].

The function $|f(z)|$ is depicted in Figure 13. From the set of its associated numerical data it can be seen that for $\Re\{z\} = 0$ we have $|f(z)| = 2.7182\ldots$ when $0 \leq \Im\{z\} \leq 2\pi \cdot 10^{-3}$ and $|f(z)| \to e$ when $\Im\{z\} \to 0$. In other words, for $|f(z)|$ to be close to $e$, it is sufficient in this case to provide that $2\pi \cdot f_{\text{max}} \cdot T_D/N \leq 2\pi \cdot 10^{-3}$, where $f_{\text{max}}$ is the maximum frequency in the spectrum of the signal $e(t)$ being transmitted through the $RLC$ ladder in Figure 8 having almost true delay equal to Elmore’s delay time $T_D$, or $N \geq f_{\text{max}} \cdot [T_D]$, where $[T_D]$ is delay time $T_D$ expressed in [ms].

The function $\arg(f(z))$ [deg] is depicted in Figure 14. From the set of its associated numerical data it can be seen that for $\Re\{z\} = 0$ we have $-0.1799964 < \arg(f(z))$ [deg] $\leq 0$ when $0 \leq \Im\{z\} \leq 2\pi \cdot 10^{-3}$ and $\arg(f(z)) \to 0$ when $\Im\{z\} \to 0$. For $\arg(f(z)) \leq 0$ to be close to 0, say to be $|\arg(f(z))| < 0.18$ [deg], it is sufficient in this case also to provide that $2\pi \cdot f_{\text{max}} \cdot T_D/N \leq 2\pi \cdot 10^{-3}$ or $N \geq f_{\text{max}} \cdot [T_D]$. For properly selected $N$ (i.e., $T_D/N \leq 1/(1000 \cdot f_{\text{max}})$), the ladder parameters are found according to the previously formulated steps (b) ÷ (c): arbitrarily select $C$ and calculate $R = (T_D/N)/C$ and $L = (T_D/N)^2/C$.

As a final example, consider the ladder in Figure 8 with parameters: $N = 500$, $C = 1 \\mu F$, $R = 10 \\Omega$, $L = 100 \\mu H$, and the Elmore’s delay time $T_D = N \cdot (L/R) = N \cdot \sqrt{L/C} = 5$ [ms]. Since condition $f_{\text{max}} \cdot T_D/N \leq 10^{-3}$ is satisfied for $f_{\text{max}} \leq 100$ [Hz], then this ladder may be used as true delay line for every input signal $e(t)$ with maximum spectral frequency up to $f_{\text{max}}$, with output $u(t)$ being almost the replica of $e(t)$ with no attenuation and virtually constant delay $T_D$ equal to Elmore’s delay time. The results for this ladder excited by various input signals $e(t)$, produced by using of PSPICE simulation, are depicted in Figures 15, 16, 17, 18 and 19. There on it may be noticed that the overall output voltage of this ladder as of artificial delay-line (ADL) is represented by $u(t) \approx e(t-T_D)$, with absolute error $\text{aer}(t) = u(t)-e(t-T_D)$.

In the paper [12] it is proved that by using distortionless transmission line with resistive load equal to the

Figure 16: PSPICE verification of delay time $T_D = 5$ [ms] for input wave $e(t)$ with period $T = 0.1$ [s], linear frequency chirp $0 \div 100$ [Hz], and linearly increasing amplitude $0 \div 10$ [V].

Figure 17: PSPICE results for transfer with delay $T_D = 5$ [ms] of CAM input wave $e(t)$ with carrier $\pm 10$ [V]/100 [Hz], modulation index $m = 0.5$, and the intelligence frequency 50 [Hz] within ADL in Figure 8.

Figure 18: PSPICE results for transfer with delay $T_D = 5$ [ms] of FM input wave $e(t)$ with carrier $\pm 10$ [V]/50 [Hz], modulation index $m = 2$ and intelligence frequency 25 [Hz] within ADL in Figure 8.

Figure 19: PSPICE results for transfer with delay $T_D = 5$ [ms] of input wave $e(t)$ with period $T = 0.1$ [s], linear frequency chirp $0 \div 100$ [Hz], and linearly increasing amplitude $0 \div 10$ [V] within ADL in Figure 8.

Figure 20: The amplitude-frequency characteristics of the considered ladder in the frequency range $f \in [0, 100]$ [Hz].

Line characteristic impedance $\sqrt{L'/C'}$ ($L'$ and $C'$ are the per-unit-length inductance and capacitance of line, resp.), even a relatively small signal delay $T_D$ cannot be realistically produced. For example, signal delay $T_D = 5$ [ms] can be realized with lossless line having the constant parameters $L' = 1.5$ [μH/m], $C' = 18$ [pF/m], and load resistance $(L'/C')^{1/2} = 500/\sqrt{3}$ [Ω], at the distance $d = T_D \cdot (L'/C')^{1/2} \approx 962.25$ [km] from the line sending end, but when distortionless line is lossy and terminated with characteristic impedance $(L'/C')^{1/2}$, then besides the time delay $d \cdot (L'/C')^{1/2}$ at distance $d$, the signal attenuation factor $\exp[d \cdot (R' \cdot G')]$ ($R'$ and $G'$ are the per-unit-length resistance and conductance of the lossy line, resp.) must be also taken into account [18]. Realization of pulse delay $T_D = 5$ [ms] with lumped $RLC$ network in Figure 8 is verified in Figure 12 and seems to be the most comfortable approach than using lengthy distributed parameter networks. In general, realization of any time delay $T_D$ for signal with maximum spectral frequency $f_{\text{max}}$ can be accomplished by using the uniform ladder in Figure 8 with length $N$ selected according to the condition $T_D/N \leq 1/(1000 \cdot f_{\text{max}})$. The ladder parameters are calculated according to relations $R = (T_D/N)/C$ and $L = (T_D/N)^2/C$, where $C$ may be selected arbitrarily.
Finally, in Figures 20 and 21 the results of PSPICE AC-analysis are depicted with 1 [V] amplitude AC-input in the entire frequency range [0, 100] [Hz] for network in Figure 8 with parameters \( N = 500, C = 1 \mu F, R = 10 \Omega , \) and \( L = 100 \mu H \). In Figure 20 we see that the amplitude-frequency characteristics of the network are *almost flat*, and in Figure 21 we see that its phase-frequency characteristics are virtually linear with slope \(-1.8 \) [deg/Hz]. Hence we conclude that the network in Figure 8 may satisfactorily realize the time delay \( T_D \) for any input signal \( e(t) \) with spectrum in range \( 0 \div 100 \) [Hz].

4. Conclusions

In the paper, are derived general, closed-form expressions for network functions of common-ground, uniform, and passive ladders with complex double terminations are derived, making distinction in analysis between the signal transfer to ladder nodes and to its points. The obtained results are then simplified for ladders with seven specific pairs of complex double terminations. Elmore’s delay and rise times calculated for specific, important types of RLC ladders indicated slight deviation from delay and rise times values obtained according to their classical definitions.

For the common-ground, integrating RC ladder with step input, Elmore’s delay and rise times are produced in closed form, both for ladder nodes and ladder points. It has been shown that this type of ladder could not be recommended as pulse delay line in its own rift, since its Elmore’s rise-times of point voltages are not less than the twice of their delay times.

And finally, in this paper we have proposed a specific type of common-ground, uniform RLC ladder amenable for application as delay line, both for pulsed and analog input signals. For this type of ladder, Elmore’s delay and rise times relating to the node voltages are produced in the closed form, which offers a possibility for realization of (a) the pulse delay line with arbitrarily specified Elmore’s delay and rise times and (b) the true delay line, both for pulsed and analog input signals, with arbitrarily selected delay time. For both cases (a) and (b), in the paper a procedure for the determination of ladder length and calculation of all its RLC parameters is specified. Recall that the ladder network topology is preferable one in the network synthesis, since it has very low sensitivity with respect to variations of RLC parameters. The obtained results are illustrated with several practical examples and are verified through PSPICE simulation.

### Appendices

**A.**

Property 1. If \( z \in \mathbb{C} \) (\( \mathbb{C} \)-set of complex numbers), then \( \cos(n \cdot z) \) is the \( n \)-th order trigonometric polynomial in \( \cos(z) \) and \( \sin(n \cdot z) \) is the product of \( \sin(z) \) and the \((n-1)\)-th order trigonometric polynomial in \( \cos(z) \).

**Proof.** Let \( j := \sqrt{-1} \), and let us make the following binomial expansion:

\[
\cos (n \cdot z) + j \cdot \sin (n \cdot z) = \left[ \cos (z) + j \cdot \sin (z) \right]^n = \sum_{k=0}^{n} \binom{n}{k} \cdot (j)^k \cdot \cos^{n-k} (z) \cdot \sin^k (z) \tag{A.1}
\]

\[
= \sum_{p=0}^{\lfloor \frac{n}{2} \rfloor} (-1)^p \left( \frac{n}{2p} \right) \cdot \cos^{n-2p} (z) \cdot \sin^{2p} (z) + j \cdot \sum_{q=0}^{\lfloor \frac{n-1}{2} \rfloor} (-1)^q \left( \frac{n}{2q+1} \right) \cdot \cos^{n-2q-1} (z) \cdot \sin^{2q+1} (z) .
\]

From (A.1) it readily follows that

\[
\cos (n \cdot z) = \sum_{p=0}^{\lfloor \frac{n}{2} \rfloor} (-1)^p \left( \frac{n}{2p} \right) \cdot \cos^{n-2p} (z) \cdot \left[ 1 - \cos^2 (z) \right]^p , \tag{A.2}
\]

\[
\sin (n \cdot z) = \sin (z) \cdot \sum_{q=0}^{\lfloor \frac{n-1}{2} \rfloor} (-1)^q \left( \frac{n}{2q+1} \right) \cdot \cos^{n-2q-1} (z) \cdot \left[ 1 - \cos^2 (z) \right]^q .
\]

Property 2. If \( z \in \mathbb{C} \), then the following finite product expansion holds:

\[
\cosh (n \cdot z) = 2^{n-1} \cdot \prod_{i=1}^{n} \left[ \cosh (z) - \cos \left( \frac{2i - 1}{2n} \cdot n \right) \right] . \tag{A.3}
\]
Proof. According to Property 1, \(\cos(n \cdot z)\) is the \(n\)th order polynomial in \(\cos(z)\). Then we have

\[
\cos(n \cdot z) = A \cdot \prod_{i=1}^{n} \left[ \cos(z) - \xi_i \right], \quad A \text{ is a constant } (A \neq 0),
\]

\[
\xi_i = \cos\left(\frac{2i - 1}{2n} \cdot \pi\right), \quad i = 1, n.
\]

(A.4)

Now, consider the complex equation \(z^{2n} = 1\) with roots \(z_k = \exp(\pm j \cdot (2k - 1)/2n) \cdot \pi\) \((k = 1, n)\). Then it holds the following factorization:

\[
z^{2n} + 1 = \prod_{k=1}^{n} \left[ (z - e^{j((2k-1)/2n)\pi}) \cdot (z - e^{-j((2k-1)/2n)\pi}) \right]
\]

\[
= \prod_{k=1}^{n} \left[ z^2 - 2 \cdot z \cdot \cos\left(\frac{2k - 1}{2n} \cdot \pi\right) + 1 \right].
\]

(A.5)

For \(z = 1\), from (A.5) we obtain the identity \(\prod_{k=1}^{n} \sin((2k - 1)/4n) \cdot \pi) = \sqrt{2}/2^n\). Then, for \(z = 0\), from (A.4) it firstly follows that \(1/A = \prod_{k=1}^{n} [1 - \cos((2i - 1)/2n) \cdot \pi\}) = 2^n \cdot (2^n) = 2^n\cdot (2^2/2^n) = 2^{n-1}, or \(A = 2^{n-1}\), and then, upon substitution \(z \rightarrow j \cdot z\), also in (A.4), the following implication is obtained:

\[
cos(n \cdot z) = 2^{n-1}
\]

\[
\cdot \prod_{i=1}^{n} \left[ \cos(z) - \cos\left(\frac{2i - 1}{2n} \cdot \pi\right) \right]
\]

\[
z \rightarrow jz \implies \cosh(n \cdot z) = 2^{n-1} \cdot \prod_{i=1}^{n} \left[ \cosh(z) - \cos\left(\frac{2i - 1}{2n} \cdot \pi\right) \right]
\]

(A.6)

Property 3. If \(z \in \mathbb{C}\), then the following finite product expansion holds:

\[
\sinh(n \cdot z) = 2^{n-1} \cdot \sinh(z)
\]

\[
\cdot \prod_{k=1}^{n-1} \left[ \sinh(z) - \cos\left(\frac{k \cdot \pi}{n}\right) \right].
\]

(A.7)

Proof. According to Property 1, \(\sin(n \cdot z)\) is the product of \(\sin(z)\) and a polynomial in \(\sin(z)\) of order \(n-1\). Then we have

\[
\sin(n \cdot z) = B \cdot \sin(z)
\]

\[
\cdot \prod_{i=1}^{n-1} \left[ \sin(z) - \xi_i \right], \quad B \text{ is a constant } (B \neq 0),
\]

\[
\xi_i = \sin\left(\frac{i \cdot \pi}{n}\right), \quad i = 1, n-1.
\]

(A.8)

Now, consider the complex equation \(z^{2n} = 1\) with roots \(z = \pm 1\) and \(z_k = \exp(\pm j \cdot (k \cdot \pi/n)) \((k = 1, n-1)\). Then the following factorization holds:

\[
z^{2n} + 1 = \prod_{k=1}^{n-1} \left[ (z - z_k) \cdot (z - z_k^*) \right]
\]

\[
= \prod_{k=1}^{n-1} \left[ z^2 - 2 \cdot z \cdot \cos\left(\frac{k \cdot \pi}{n}\right) + 1 \right].
\]

(A.9)

wherefrom, for \(z = 1\), we obtain the identity \(\prod_{k=1}^{n} \sin(k \cdot \pi/2n) = \sqrt{n}/2^{n-1}\). Then, for \(z = 0\), from (A.8) it firstly follows that \(\prod_{k=1}^{n} \sin(k \cdot \pi/n) = 2^{n-1}, \prod_{k=1}^{n} \sin(i \cdot \pi/2n) = 2^{n-1} \cdot (n/2^{n-2}) = n \cdot 2^{n-1}\), and then, upon substitution \(z \rightarrow j \cdot z\), also in (A.8), the following implication is obtained:

\[
\sin(n \cdot z) = 2^{n-1} \cdot \sinh(z)
\]

\[
\cdot \prod_{i=1}^{n-1} \left[ \cosh(z) - \cos\left(\frac{i \cdot \pi}{n}\right) \right] \implies \sinh(n \cdot z) = 2^{n-1} \cdot \sinh(z) \cdot \prod_{i=1}^{n-1} \left[ \cosh(z) - \cos\left(\frac{i \cdot \pi}{n}\right) \right]
\]

(A.10)

Remark 1. From proofs of Properties 2 and 3, we explicitly emphasize the following two identities having been obtained in passing

\[
\prod_{k=1}^{n} \sin\left(\frac{2k - 1}{4n} \cdot \pi\right) = \frac{\sqrt{2}}{2^n},
\]

(A.11)

\[
\prod_{k=1}^{n} \sin\left(\frac{k \cdot \pi}{2n}\right) = \frac{\sqrt{n}}{2^{n-1}}.
\]

Property 4. If \(x \in \mathbb{R}\) (\(\mathbb{R}\)-set of real numbers), then the following identity holds:

\[
2^{n-1} \cdot \prod_{k=0}^{n-1} \sin\left(\frac{x + \frac{k \cdot \pi}{n}\right) = \sin(n \cdot x).
\]

(A.12)

Proof. The roots of the polynomial \(z^{2n} - 2 \cdot [\cos(2 \cdot n \cdot x)] \cdot z^n + 1 = 0\) are \(\exp[-j \cdot (\pm 2 \cdot x + 2 \cdot k \cdot \pi/n)]\) \((k \in \mathbb{N}, n-1)\), and they can be written in the following form: \(z_k = \exp[j \cdot (2 \cdot x + 2 \cdot k \cdot \pi/n)]\) and \(z_k^* = \exp[-j \cdot (2 \cdot x + 2 \cdot k \cdot \pi/n)]\) \((k = 0, n-1)\). The considered polynomial has the following factorization:

\[
z^{2n} - 2 \cdot [\cos(2 \cdot n \cdot x)] \cdot z^n + 1
\]

\[
= \prod_{k=0}^{n-1} \left[ (z - z_k) \cdot (z - z_k^*) \right]
\]

\[
= \prod_{k=0}^{n-1} \left[ z^2 - 2 \cdot z \cdot \cos\left(\frac{2 \cdot x + 2 \cdot k \cdot \pi}{n}\right) + 1 \right].
\]

(A.13)
wherefrom for \( z = 1 \) it follows that
\[
|\sin(n \cdot x)| = 2^{n-1} \left| \prod_{k=0}^{n-1} \sin \left( x + \frac{k \cdot \pi}{n} \right) \right|.
\] (A.14)

It is easy to see that if \( \sin(n \cdot x) \geq 0 \) \( \Leftrightarrow x \in [2 \cdot m \cdot \pi, 2 \cdot m \cdot \pi + \pi/n], m \in \mathbb{N} \) (\( \mathbb{N} \) is the set of natural numbers)), then \( \sin(x + k \cdot \pi/n) \geq 0, \) for \( k = 0, n - 1. \) And the opposite, if \( \sin(n \cdot x) < 0 \) \( \Leftrightarrow x \in (2 \cdot m \cdot \pi + \pi/n, 2 \cdot m \cdot \pi + 2\pi/n), m \in \mathbb{N}, \) then, for \( k = 0, n - 2, \) we see that it holds \( \sin(x + k \cdot \pi/n) > 0 \) and for \( k = n - 1 \) it holds \( \sin(x + k \cdot \pi/n) < 0. \) Hence, we have proved that modulus signs can be lifted on both sides of the relation (A.14) and therefrom the relation (A.12) follows. \( \Box \)

**Corollary 2.** At its regular points, the function \( f(x) \ (x \in \mathbb{R}) \) is equal to zero:
\[
f(x) = \sum_{k=0}^{n-1} \frac{1}{\sin^2 (x + (k \cdot \pi/n))} = n \cdot \cos (n \cdot x), \quad (A.15)
\]

*Proof.* By differentiating (A.12) in \( x \) we easily obtain that in regular points of \( f(x) \) it holds that
\[
2^{n-1} \prod_{k=0}^{n-1} \sin \left( x + \frac{k \cdot \pi}{n} \right) \\
\cdot \sum_{k=0}^{n-1} \cotan \left( x + \frac{k \cdot \pi}{n} \right) = n \cdot \cos (n \cdot x),
\] (A.16)

or
\[
\sum_{k=0}^{n-1} \cotan \left( x + \frac{k \cdot \pi}{n} \right) = n \cdot \cotan (n \cdot x),
\]

and by differentiating in \( x \) the second relation in (A.16), (A.15) immediately follows. Observe that the statement of this corollary also holds if in (A.14) \( k \) runs from 1 to \( n \) (instead from 0 to \( n - 1 \)). \( \Box \)

**Corollary 3.** The following two identities hold:
\[
\sum_{k=1}^{n} \frac{1}{\sin^2 (((2 \cdot k - 1) / (4 \cdot n)) \cdot \pi))} = 2 \cdot n^2,
\]

\[
\sum_{k=1}^{n} \frac{1}{\sin^4 (((2 \cdot k - 1) / (4 \cdot n)) \cdot \pi))} = \frac{4}{3} \cdot n^2 \cdot (2 \cdot n^2 + 1).
\] (A.17)

*Proof.* If in (A.15) of Corollary 3 we make the substitution \( n \rightarrow 2 \cdot n \), then let \( k \) runs from 1 to \( 2 \cdot n \), and finally select \( x = -\pi/(4 \cdot n) \), the relation (A.15) is being transformed into the following form:
\[
\sum_{k=1}^{2n} \frac{1}{\sin^2 (((2 \cdot k - 1) / (4 \cdot n)) \cdot \pi))} = 4 \cdot n^2
\]

Since the 4th and the \((2n-k+1)\)th entries are equal \( \forall k = \frac{2n}{\pi} \) \( A.18 \)

\[
\sum_{k=1}^{n} \frac{1}{\sin^2 (((2 \cdot k - 1) / (4 \cdot n)) \cdot \pi))} = 2 \cdot n^2,
\]

and thus with the first of relations in (A.17) is proved. Now, suppose that in (A.15) \( k \) runs from 1 to \( n \), and differentiate this relation twice. As a result, after some manipulations, it is obtained that
\[
\sum_{k=1}^{n} \frac{1}{\sin^4 ((x + (k \cdot \pi/n))} = \frac{n^2}{\sin^2 (n \cdot x)} \cdot \left[ \frac{n^2}{\sin^2 (n \cdot x)} + 2 \cdot \left( 1 - n^2 \right) \right].
\] (A.19)

If in (A.19) we make the substitution \( n \rightarrow 2 \cdot n \), let \( k \) runs from 1 to \( 2 \cdot n \), select \( x = -\pi/(4 \cdot n) \), and finally use the same arguments as in (A.18), we immediately obtain the second of relations in (A.17). \( \Box \)

**B.**

Let \( T(s) \) be the voltage transfer function of linear, lumped electrical network with zero initial conditions, and let \( T_r(s) \) be its normalized form \( T(s)/T(0) \):
\[
T(s) = T(0) \cdot \frac{1 + \alpha_1 \cdot s + \alpha_2 \cdot s^2 + \cdots + \alpha_j \cdot s^j}{1 + b_1 \cdot s + b_2 \cdot s^2 + \cdots + b_j \cdot s^j},
\]

\[
T_r(s) = \frac{1 + \alpha_1 \cdot s + \alpha_2 \cdot s^2 + \cdots + \alpha_j \cdot s^j}{1 + b_1 \cdot s + b_2 \cdot s^2 + \cdots + b_j \cdot s^j},
\] (B.1)

where usually it holds that \( j > i \), since for most lumped physical systems the number of poles in transfer function is larger than the number of zeros. The normalized unit-step response \( u_t(t) \) of this network and its normalized impulse response \( h_t(t) \) are related through relations \( h_t(t) = du_t(t)/dt = \mathcal{L}^{-1}[T_r(s)] \) and \( u_t(t) = \mathcal{L}^{-1}[T_r(s)/s] \). In the absence of the initial conditions \( \{ \Rightarrow u_t(0) = 0 \} \) we have \( u_t(\infty) = T_r(0) = 1. \) Convenient definitions of delay time \( (T_D) \) and rise time \( (T_R) \) of a network (or other physical
systems), applicable only when its step response is monotonic (nonovershooting), originate from Elmore [7]:

\[
T_D := \int_0^\infty t \cdot h_v(t) \cdot dt,
\]

\[
T_R := \sqrt{2\pi} \cdot \left[ \int_0^\infty (t - T_D)^2 \cdot h_v(t) \cdot dt - T_D^2 \right],
\]

\[
\int_0^\infty h_v(t) \cdot dt = u_v(\infty) - u_v(0)
\]

\[= T_v(0) - T_v(\infty) = 1.\]

In many practical situations it has been noticed that, when the unit-step response of a network, or system, has no overshoot less than 5% of its steady-state unity value, (B.2) will still be holding and the obtained results will be in close agreement with those produced by using the conventional definitions of delay and rise times [7]. Since \(T_v(s) = \mathcal{L}[h_v(t)]\), then from Elmore’s definitions (B.2) it is obtained that

\[
T_v(s) = \int_0^\infty h_v(t) \cdot e^{-st} \cdot dt
\]

\[= \int_0^\infty h_v(t) \cdot \sum_{k=0}^\infty (-1)^k \cdot \frac{(st)^k}{k!} \cdot dt \]

\[= \int_0^\infty h_v(t) \cdot dt - s \cdot \int_0^\infty t \cdot h_v(t) \cdot dt + \frac{s^2}{2} \]

\[\cdot \int_0^\infty t^2 \cdot h_v(t) \cdot dt - \cdots \]

\[= 1 - s \cdot T_D + \frac{s^2}{2} \cdot \left( \frac{T_R^2}{2\pi} + T_D^2 \right) - \cdots ,\]

and after the application of the long division on \(T_v(s)\) in (B.1) it follows that

\[
T_v(s) = 1 - (b_1-a_1) \cdot s
\]

\[+ (b_1 - a_1 \cdot b_1 + a_2 - b_2) \cdot s^2 + \cdots .\]

Finally, from (B.3) and (B.4) we easily identify Elmore’s times as functions of only the coefficients \(a_1, a_2, b_1,\) and \(b_2\) [19]:

\[
T_D = b_1 - a_1,
\]

\[
T_R = \sqrt{2 \cdot \pi \left[ b_1^2 - a_1^2 + 2 \cdot (a_2 - b_2) \right]} .
\]
