An extended model predictive control algorithm is proposed to address constrained robust model predictive control. New upper bounds on arbitrarily long time intervals are derived by introducing two external parameters, which can relax the requirements for the increments of the Lyapunov function. The main merit of this new approach compared to other well-known techniques is the reduced conservativeness. The proposed method is proved to be effective for a class of uncertain fuzzy Markov jump systems with partially unknown transition probabilities. A single pendulum example is given to illustrate the advantages and effectiveness of the proposed controller design method.

1. Introduction

Model predictive control (MPC), a powerful strategy for dealing with input and state constraints for a control system, has first attracted notable attention in industrial applications [1]. Since stability analysis approach for MPC was proposed, many significant advances in understanding MPC from a control theoretician’s viewpoint have then been acquired [2–4]. Meanwhile, the MPC formulation for constrained linear systems has been naturally extended to not only nonlinear systems [5–7] but also some more complex systems, for example, stochastic systems [8, 9], time-delay systems [10], hybrid systems [11], uncertain systems [12], and so on. By employing the idea of control structure optimization, for example, distributed MPC [13], centralized MPC, and coordinated MPC, the theory of MPC has been further refined. As is well known, for a long time, efficient setting of the large set of tunable parameters has been a hard problem for MPC. Fortunately, many available methods have already been developed (see [14] and the references therein for more details). Nowadays, many scholars tend to develop “fast MPC” in order to ease the huge online computational burden [15–17]. However, it should be noticed that MPC algorithm may perform very poorly when model mismatch occurs in spite of the inherent robustness provided by the feedback strategy based on the plant measurement at the next sampling time.

Therefore, in the past decades, the issues of MPC algorithm for uncertain systems have been addressed much in the literature. A robust constrained MPC scheme considering two classes of system uncertainty, that is, polytopic paradigm and structured feedback uncertainty, has been analyzed by means of linear matrix inequalities (LMIs) by Kothare et al. [18]. As opposed to a single linear static state-feedback law in [18], Bloemen et al. [19] divided the input sequence into two parts, the first $H_2$ inputs being computed by finite MPC method and the other inputs being calculated based on linear static state-feedback law. Because $H_2$ was variable, the
end-point state-weighting matrix and the invariant ellipsoid were transformed into variables in the online optimization, and thus this algorithm achieved the trade-off between feasibility and performance. This work has been improved by applying parameter-dependent Lyapunov function [20–22]. In [23–25], an efficient robust constrained MPC with a time-varying terminal constraint set was developed. The proposed algorithm can obtain a perfect control schema achieving lower online computation and larger stabilizable set of states while retaining the unconstrained optimal performance as much as possible. It is worth mentioning that in order to analyze the stability of the system and obtain an upper bound of cost function, the optimal cost function has been qualified as a constraint on the increments of Lyapunov function [26]. However, this constraint is too strict, since to guarantee the system stability, the increments of Lyapunov function are only required to be negative. Motivated by this, in the present paper, a modified MPC scheme in which two extra parameters are introduced is proposed based on the characteristics of convergent series in order to reduce the conservativeness.

Many real systems, such as solar thermal receivers, economic systems, and networked control systems, may experience random abrupt changes in system inputs, internal variables, and other system parameters. Uncertainties like these are best represented via stochastic models [27–29], such as fuzzy Markov jump system (MJ S) in which the subsystems are modeled as fuzzy systems. Based on the approximation property of the fuzzy logic systems [30–32], fuzzy MJ Ss are developed for the nonlinear control systems with abrupt changes in their structure and parameters.

In this paper, the problem of MPC controller design for a class of uncertain fuzzy MJ Ss with partially unknown transition probabilities is addressed. This kind of system fits into a very wide range of practical dynamic systems combining nonlinear behaviors with changes or uncertainties of structure or parameters. Meanwhile, constraints, such as energy limitation, levels in tanks, flows in piping, and maximum of pH value, can be systematically included during the controller design process. The system concerned is much more complex than fuzzy systems with uncertainties or MJ Ss with partially unknown transition probabilities [33, 34], because here the uncertainties will consist of four levels (the system parameter uncertainty, the membership degree uncertainty, the mode uncertainty, and the transition probability uncertainty) and they are not mutually independent. Therefore, although the formulation seems similar, the results for fuzzy systems with uncertainties or MJ Ss with partially unknown transition probabilities cannot be directly used in this scenario. A comparison with the method in [20] (modified in [22]) is carried out by simulation on a single pendulum control problem. Due to LMIs’ prevalence in convex optimization problems, especially for the cases with high order matrices, and the availability of reliable general commercial solvers, the LMI algorithm is employed to deal with the underlying optimization problems in this study. The remainder of this paper is organized as follows. The mathematical model of the concerned system is formulated and some preliminaries are given in Section 2. Section 3 is devoted to deriving the results for the controller design. Numerical examples are provided in Section 4 and this paper is concluded in Section 5.

Notation. The notation used throughout the paper is fairly standard. The superscript “T” stands for matrix transposition. \(\mathbb{R}^n\) denotes the n-dimensional Euclidean space. The notation \(P > 0\) means that \(P\) is real symmetric and positive (semipositive) definite and \(A > B\) means \(A - B > 0\) (\(\geq 0\)). In symmetric block matrices or complex matrix expressions, we use an asterisk (*) to represent a term that is induced by symmetry and diag\{\cdots\} stands for a block-diagonal matrix. 1 and 0 represent identity matrix and zero matrix, respectively. Matrices, if their dimensions are not explicitly stated, are assumed to be compatible for algebraic operations. \(\|\cdot\|_2\) stands for the usual Euclidean norm.

### 2. Problem Formulation and Preliminaries

#### 2.1. Uncertain Fuzzy MJ Ss with Partially Unknown Transition Probabilities

Consider the following time-varying discrete-time fuzzy Markov jump system. For each mode \(r_k\), the fuzzy model is composed of \(s\) plant rules that can be represented as follows.

**Plant Rule i.** If \(\theta_i(k) = f_i^1, \ldots, f_i^d\), then

\[
\begin{align*}
\dot{x}(k+1) &= A_{ij}(r_k) x(k) + B_{ij}(r_k) u(k), \\
y(k) &= C_{ij}(r_k) x(k),
\end{align*}
\]

where \(x(k) \in \mathbb{R}^n\) is the state vector, \(u(k) \in \mathbb{R}^m\) is the control input, \(y(k) \in \mathbb{R}^p\) is the system output, \(\theta \in \{\theta_1, \ldots, \theta_s\}^T\) is the premise variable vector, \(d\) is the number of premise variables, and \(\{f_j, i \in S, j \in \{1, 2, \ldots, d\}\}\) is a fuzzy set.

Taking values in a finite set \(\mathcal{F} \cong \{1, \ldots, N\}\), governing switching among different system modes. The system matrices of the \(r_k\) mode are denoted by \([A_i(r_k), B_i(r_k), C_i(r_k)] \in \Omega(r_k, i)\) and the set \(\Omega(r_k, i)\) is a set of polytopes

\[
\Omega(r_k, i) \doteq \text{Co} \{[A_{i1}(r_k), \ldots, A_{iL}(r_k)], [A_{i2}(r_k), \ldots, A_{iL}(r_k)], \ldots, [A_{iL}(r_k), \ldots, A_{iL}(r_k)]\},
\]

where Co denotes the convex hull. In other words, if \([A_i(r_k, k), B_i(r_k, k), C_i(r_k, k)] \in \Omega(r_k, i)\), then for some nonnegative \(\lambda_j(i, r_k, k), j \in \{1, L\}\) summing to one, the following holds:

\[
[A_i(r_k, k), B_i(r_k, k), C_i(r_k, k)] = \sum_{j=1}^L \lambda_j(i, r_k, k) [A_{ij}(r_k), B_{ij}(r_k), C_{ij}(r_k)].
\]

For the sake of simplicity, we denote \(\{1, 2, \ldots, L\}\) by \(L\) and \(A_i(r_k, k), B_i(r_k, k), C_i(r_k, k)\), and \(\lambda_j(i, r_k, k)\) by \(A^k_{ir_k}, B^k_{ir_k}, C^k_{ir_k}\), and \(\lambda^k_{ir_k}\), respectively.
As commonly done in the literature, it is assumed that the premise variable vector \( \theta \) does not depend on the control variables and the disturbance. The center-average defuzzification method is used as follows:

\[
h_i[\theta(k)] = \frac{\prod_{j=1}^{d} \mu_{ij} \theta_j(k)}{\sum_{l=1}^{s} \prod_{j=1}^{d} \mu_{lj} \theta_j(k)} \geq 0, \quad i \in \mathbb{S},
\]

\[
\sum_{i=0}^{s} h_i[\theta(k)] = 1,
\]

where \( \mu_{ij}[\theta_j(k)] \) is the grade of membership of \( \theta_j(k) \) in \( f_j \).

In what follows, we use the following notation for simplicity: \( h_{ij} = h_i[\theta(k + l)] \).

A more compact presentation of system (1) is given by

\[
\Sigma : x(k + 1) = \sum_{i=1}^{s} h_i^{(k)} \left( A_{ri} x(k) + B_{ri} u(k) \right)
\]

\[
y(k) = \sum_{i=1}^{s} h_i^{(k)} C_{ri} x(k), \quad r_k \in \mathcal{F}.
\]

The process \( r_k, k \geq 0 \) is described by a discrete-time homogeneous Markov chain, which takes values in the finite set \( \mathcal{F} \) with mode transition probabilities

\[
Pr(r_{k+1} = j \mid r_k = i) = \pi_{ij},
\]

where \( \pi_{ij} \geq 0, \forall (i, j) \in \mathcal{F} \times \mathcal{F} \), and \( \sum_{i=1}^{N} \pi_{ij} = 1 \). For example, the transition probability matrix (TPM) can be given by

\[
\Pi = \begin{bmatrix}
\pi_{11} & \hat{\pi}_{12} & \cdots & \hat{\pi}_{1N} \\
\hat{\pi}_{21} & \pi_{22} & \cdots & \pi_{2N} \\
\vdots & \vdots & \ddots & \vdots \\
\hat{\pi}_{N1} & \pi_{N2} & \cdots & \pi_{NN}
\end{bmatrix},
\]

The transition probabilities described above are considered to be partially available and can be divided into two parts as

\[
\mathcal{F}^{(0)}_{\pi} = \left\{ j : \pi_{ij} \text{ is known} \right\}, \quad \mathcal{F}^{(0)}_{\hat{\pi}} = \left\{ j : \hat{\pi}_{ij} \text{ is unknown} \right\}.
\]

In addition, if \( \mathcal{F}^{(0)}_{\pi} \neq \emptyset \), \( \mathcal{F}^{(0)}_{\hat{\pi}} \) is further described as

\[
\mathcal{F}^{(0)}_{\pi} = \left\{ \mathcal{H}_1, \mathcal{H}_2, \ldots, \mathcal{H}_{z_1} \right\}, \quad z_1 \in \{1, 2, \ldots, N-2 \},
\]

where \( \mathcal{H}_s \in \mathbb{N}^{+} \), \( s \in \{ 1, 2, \ldots, z_1 \} \), represents the index of the \( s \)th known element in the \( i \)th row of matrix \( \Pi \). We denote

\[
\pi_{\mathcal{H}_s}(i) = \sum_{j \in \mathcal{F}^{(0)}_{\pi}} \pi_{ij}.
\]

The following fuzzy control law is chosen:

\[
u(k) = \sum_{p=1}^{s} h_p^{(k)} F_p(r_k) x(k), \quad r_k \in \mathcal{F}.
\]

Under the control law, the closed-loop system of \( \Sigma \) is given by

\[
\Sigma^C : x(k + 1) = \sum_{p=1}^{s} h_p^{(k)} F_p A_{p\mathcal{H}_s} x(k),
\]

\[
y(k) = \sum_{p=1}^{s} h_p^{(k)} C_p x(k), \quad r_k \in \mathcal{F},
\]

where \( A_{p\mathcal{H}_s} = A_{p\mathcal{H}_s}(r_k, k) \neq A_{p\mathcal{H}_s} + B_{p\mathcal{H}_s} F_p(r_k) \).

For the fuzzy MJS, the following definition will be adopted in the rest of this paper.

**Definition 1.** The fuzzy MJS in (12) is said to be stochastically stable, if for any initial condition \( x(0) = x_0, r_0 \in \mathcal{F} \), the following inequality holds:

\[
\lim_{N \to \infty} E \left( \sum_{k=0}^{N} \left\| x(k, x_0, r_0) \right\|_2^2 \right) < \infty,
\]

where \( E[\cdot] \) stands for the mathematical expectation.

The objective of this paper is to design a state-feedback model predictive controller such that the closed-loop system (12) is stochastically stable.

**2.2. Model Predictive Control.** Model predictive control (MPC) makes use of a receding horizon principle, which means that at each sampling time \( k \), an optimization algorithm will be applied to compute a sequence of future control signals. The used performance index depends on the predicted future states of the plant \( x(k+i \mid k), i \geq 0 \), which can be calculated through the newly obtained measurements \( x(k) \) and the predictive model. Here, we use \( x(k+i \mid k) \), \( y(k+i \mid k) \) as the state and output, respectively, of the plant at time \( k+i \) predicted by utilizing the measurements at time \( k \); \( u(k+i \mid k) \) represents the control action moves at time \( k+i \) computed by the optimization problem (14); \( P \) is the prediction horizon and \( M \) is the control horizon. In what follows, let \( P \) and \( M \) represent \( \{0, 1, \ldots, P\} \) and \( \{0, 1, \ldots, M\} \), respectively.

In this section, the problem formulation for MPC using the model (12) is discussed. The goal is to find an input sequence \( \{ u(k \mid k), u(k+1 \mid k), \ldots, u(k+M-1 \mid k) \} \) at each sampling time \( k \) which minimizes the following performance index \( J(k) \):

\[
\min_{u(k+i \mid k), i \in \mathbb{M}} J(k),
\]

where

\[
J(k) = E \left\{ \sum_{i=0}^{P} x(k+i \mid k)^T Q x(k+i \mid k) + \sum_{j=0}^{M} u(k+j \mid k)^T R u(k+j \mid k) \right\},
\]
and then it can be replaced by

\[
\min_{u(k+i|k), \in \mathbb{P}} \left[ \sum_{j=1}^{\mathcal{P}} \max_{\mathcal{A}_{r_j}^{k+i} \mathcal{B}_{r_j}^{k+i} \mathcal{C}_{r_j}^{k+i} \in \Omega(r_j,i), i \in \mathbb{P}, j \in \mathbb{S}} J(k) \right],
\]

where \( \mathcal{P} \) is the system state. Assume that there exists a convergent series \( a_k \), such that, at each sampling time \( k \), the following inequality holds for all \( x(k+i | k) \), \( u(k+i | k) \), \( i \in \mathbb{P} \) satisfying (12):

\[
E \left\{ V(x(k+i+1 | k)) - V(x(k+i | k)) \right\} \leq \frac{1}{\beta} E \left\{ 1 \right\} V(x(k+i | k)) + S(k) \].

Summing (21) from \( i = 0 \) to \( i = P \), we get

\[
E \left\{ V(x(k+P | k)) - V(x(k+i | k)) \right\} \leq -\beta \left( J(k) - S(k) \right),
\]

where \( S(k) = \sum_{i=0}^{P} a_{k+i} \). Thus

\[
\max_{\mathcal{A}_{r_j}^{k+i} \mathcal{B}_{r_j}^{k+i} \mathcal{C}_{r_j}^{k+i} \in \Omega(r_j,i), i \in \mathbb{P}, j \in \mathbb{S}} J(k) \leq \frac{1}{\beta} E \left\{ V(x(k+i | k)) \right\} + S(k) \].

Specially, when \( P = M = \infty \), we will have \( x(\infty | k) = 0 \) for the robust performance objective function to be finite and hence \( V(x(\infty, k)) = 0 \). Summing (21) from \( i = 0 \) to \( i = \infty \), we get

\[
E \left\{ -V(x(k+i | k)) \right\} \leq -\beta \left( J(k) - b \right).
\]

Thus

\[
\max_{\mathcal{A}_{r_j}^{k+i} \mathcal{B}_{r_j}^{k+i} \mathcal{C}_{r_j}^{k+i} \in \Omega(r_j,i), i \in \mathbb{P}, j \in \mathbb{S}} J(k) \leq \frac{1}{\beta} E \left\{ V(x(k+i | k)) \right\} + b.
\]

Consider a parameter-dependent function

\[
V(x(k+i | k)) = x(k+i | k)^T \left( \sum_{j=1}^{\mathcal{P}} \mathcal{A}_{r_j}^{k+i} \mathcal{B}_{r_j}^{k+i} \mathcal{D}_{r_j}^{k+i} \right) x(k+i | k), \quad k \geq 0, \quad i \in \mathbb{P},
\]

where \( \mathcal{D}_{r_j}^{k+i} > 0 \). For the robust performance objective function to be finite, we will have \( x(k+i | k) \in [X_{\min} X_{\max}] \) and \( x(k+i | k) \leq X_{\max} \); hence, \( a_{k+i} \leq X_{\max} a_{k+i} \). Therefore, (21) can be written as

\[
E \left\{ V(x(k+i+1 | k)) - V(x(k+i | k)) \right\} \leq -\beta \left( x(k+i | k)^T Q x(k+i | k) + u(k+i | k)^T R u(k+i | k) \right) + \beta x(k+i | k)^T C_{k+i}^T I x(k+i | k).
\]
In order to guarantee the increment $\Delta V(k) \leq 0$, $c_k I < Q$ is required. This gives an upper bound on the robust performance objective. Thus the goal of our robust MPC algorithm has been redefined to deduce, at each time step $k$, a state-feedback control law $u(k+i \mid k) = \sum_{p=1}^{s} h_p^{k+i} F_p(r_k) x(k+i \mid k)$ to minimize this upper bound $E[(1/\beta)V(x(k \mid k)) + b]$, that is to say, $E[V(x(k \mid k))]$.

3.2. Minimization of the Upper Bound without Constraints

**Theorem 2.** Consider the closed-loop uncertain system (12) with the polytopic uncertainty set $\Omega(r_k, i), r_k \in \mathcal{F}, i \in \mathbb{S}$. Let $x(k) = x(k \mid k)$ be the state measured at sampling time $k$. Assume that there are no constraints on the control input and plant output. Then the state-feedback matrix $F_p(r_{k+i})$ in the control law $u(k+i \mid k) = \sum_{p=1}^{s} h_p^{k+i} F_p(r_k) x(k+i \mid k)$, $i \in \mathbb{P}$, that minimizes the upper bound $E[(1/\beta)V(x(k \mid k)) + b]$ on the robust performance objective function at sampling time $k$ is given by

$$F_p(r_{k+i}) = Y_p(r_{k+i}) G^{-1}, \quad (28)$$

where $G > 0$ and $Y_p(r_{k+i})$ are obtained from the solution (if it exists) to the following linear objective minimization problem:

$$\begin{align*}
\min_{\gamma \in \mathbb{L}, Y} & \gamma \\
\text{subject to} & \begin{bmatrix} 1 & x(k \mid k) ^T \end{bmatrix} \begin{bmatrix} x(k \mid k) \\
\mathcal{E}_{p} (r_{k+i}) \\
\mathcal{E}_{p} (r_{k+i}) & R_f \end{bmatrix} \begin{bmatrix} x(k \mid k) \\
\mathcal{E}_{p} (r_{k+i}) \\
\mathcal{E}_{p} (r_{k+i}) & R_f \end{bmatrix} \begin{bmatrix} x(k \mid k) \\
\mathcal{E}_{p} (r_{k+i}) \\
\mathcal{E}_{p} (r_{k+i}) & R_f \end{bmatrix} \lesssim 0, \quad \forall i \in \mathbb{P}, \\
p \in \mathbb{S}, \ j \in \mathbb{L}, \ r_k \in \mathcal{F}, \\
[ G + G^T - \mathcal{E}_{p} (r_{k+i}) & * & * \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
[ \beta^{1/2} (Q - \mathcal{E}_{p} I)^{1/2} & 0 & \gamma I * \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
[ \beta^{1/2} R_f^{1/2} Y_p (r_{k+i}) & 0 & 0 & \gamma I \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
p \geq q, \ w \in \mathbb{S}, \ j, v, f \geq 0 \in \mathbb{L}, \ r_{k+i} \in \mathcal{F}, \ g \in \mathcal{G}_{p_{r_{k+i}}}, \end{align*} \quad (29)$$

Proof. Minimization of the upper bound means minimizing $V(x(k \mid k))$ which is equivalent to

$$\begin{align*}
\min_{\gamma \in \mathbb{L}} & \gamma \\
\text{subject to} & \begin{bmatrix} 1 & x(k \mid k) ^T \end{bmatrix} \begin{bmatrix} x(k \mid k) \\
\mathcal{E}_{p} (r_{k+i}) \\
\mathcal{E}_{p} (r_{k+i}) & R_f \end{bmatrix} \begin{bmatrix} x(k \mid k) \\
\mathcal{E}_{p} (r_{k+i}) \\
\mathcal{E}_{p} (r_{k+i}) & R_f \end{bmatrix} \lesssim 0, \quad \forall i \in \mathbb{P}, \\
p \in \mathbb{S}, \ j \in \mathbb{L}, \ r_k \in \mathcal{F}, \\
[ G + G^T - \mathcal{E}_{p} (r_{k+i}) & * & * \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
[ \beta^{1/2} (Q - \mathcal{E}_{p} I)^{1/2} & 0 & \gamma I * \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
[ \beta^{1/2} R_f^{1/2} Y_p (r_{k+i}) & 0 & 0 & \gamma I \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
p \geq q, \ w \in \mathbb{S}, \ j, v, f \geq 0 \in \mathbb{L}, \ r_{k+i} \in \mathcal{F}, \ g \in \mathcal{G}_{p_{r_{k+i}}}, \end{align*} \quad (31)$$

Defining $\mathcal{E}_{p} (r_{k+i}) \triangleq \gamma \mathcal{F}_{p_{r_{k+i}}}^{-1} (r_{k+i}) > 0$ and using Schur complements, this is equivalent to

$$\begin{align*}
\min_{\gamma \in \mathbb{L}} & \gamma \\
\text{subject to} & \begin{bmatrix} 1 & x(k \mid k) ^T \end{bmatrix} \begin{bmatrix} x(k \mid k) \\
\mathcal{E}_{p} (r_{k+i}) \\
\mathcal{E}_{p} (r_{k+i}) & R_f \end{bmatrix} \begin{bmatrix} x(k \mid k) \\
\mathcal{E}_{p} (r_{k+i}) \\
\mathcal{E}_{p} (r_{k+i}) & R_f \end{bmatrix} \lesssim 0, \quad \forall i \in \mathbb{P}, \\
p \in \mathbb{S}, \ j \in \mathbb{L}, \ r_k \in \mathcal{F}, \\
[ G + G^T - \mathcal{E}_{p} (r_{k+i}) & * & * \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
[ \beta^{1/2} (Q - \mathcal{E}_{p} I)^{1/2} & 0 & \gamma I * \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
[ \beta^{1/2} R_f^{1/2} Y_p (r_{k+i}) & 0 & 0 & \gamma I \] \lesssim 0, \quad \forall i \in \mathbb{P}, \\
p \geq q, \ w \in \mathbb{S}, \ j, v, f \geq 0 \in \mathbb{L}, \ r_{k+i} \in \mathcal{F}, \ g \in \mathcal{G}_{p_{r_{k+i}}}, \end{align*} \quad (32)$$

The parameter-dependent function $V$ is required to satisfy (27). By substituting

$$u(k+i \mid k) = \sum_{p=1}^{s} h_p^{k+i} F_p(r_k) x(k+i \mid k), \quad i \in \mathbb{P}, \quad (33)$$

and the state-space equations in (12), inequality (27) becomes
\[
+ \beta F_p(r_{k+i})^T R F_q(r_{k+i}) + \beta Q - \beta \tilde{c}_{k+i} I} \\
\times x(k + i | k)
\]

\[
= x(k + i | k)^T \sum_{p=1}^{s} \sum_{q=1}^{s} \sum_{m=1}^{s} \sum_{n=1}^{s} \sum_{l=1}^{s} \sum_{L=1}^{L} \sum_{N=1}^{N} \sum_{k_{r+i+1}}^{k_{r+i+1}} \sum_{k_{r+i}}^{k_{r+i}} \sum_{L=1}^{L} \sum_{N=1}^{N} \sum_{k_{r+i+1}}^{k_{r+i+1}} \sum_{k_{r+i}}^{k_{r+i}} \lambda_{r+i}
\]

\[
\times \left\{ A^T_{pmr_{k+i}} \cdot \pi_{r_{k+i+1}r_{k+i}} \mathcal{P}_{q,r_{k+i+1}} A_{nnm_{k+i+1}} - \mathcal{P}_{p,j}(r_{k+i}) + \beta F_p(r_{k+i})^T R F_q(r_{k+i}) + \beta Q - \beta \tilde{c}_{k+i} I \right\} (k + i | k) \leq 0.
\]

This is equivalent to

\[
\sum_{p=1}^{s} \sum_{q=1}^{s} \sum_{m=1}^{s} \sum_{n=1}^{s} \sum_{l=1}^{s} \sum_{L=1}^{L} \sum_{N=1}^{N} \sum_{k_{r+i+1}}^{k_{r+i+1}} \sum_{k_{r+i}}^{k_{r+i}} \sum_{L=1}^{L} \sum_{N=1}^{N} \sum_{k_{r+i+1}}^{k_{r+i+1}} \sum_{k_{r+i}}^{k_{r+i}} \lambda_{r+i}
\]

\[
\times \left\{ A^T_{pmr_{k+i}} \cdot \pi_{r_{k+i+1}r_{k+i}} \mathcal{P}_{q,r_{k+i+1}} A_{nnm_{k+i+1}} - \mathcal{P}_{p,j}(r_{k+i}) + \beta F_p(r_{k+i})^T R F_q(r_{k+i}) + \beta Q - \beta \tilde{c}_{k+i} I \right\}
\]

\[

&\times h_{p}^{k+i} h_{q}^{k+i} h_{m}^{k+i} h_{n}^{k+i} h_{w}^{k+i} \lambda_{wvr_{k+i}}^{k+i} \lambda_{pjr_{k+i}}^{k+i} \\
&\times \mathcal{P}_{uv}(g) + \sum_{l \in \mathcal{F}(l)} \frac{\pi_{k+i} (l)}{1 - \pi_{k+i} (r_{k+i})} \mathcal{P}_{uv}(l) \right\} \\
&\times \left\{ (A_{pqrs} + A_{pqr}) - 4\mathcal{P}_{pj}(r_{k+i}) \\
+ 4\beta F_{p}(r_{k+i})^T RF_{p}(r_{k+i}) + 4\beta Q - 4\beta \kappa_{k+i}I \right\} \\
Then, (34) is satisfied for all $i \in P$ if

\[
\frac{A^T_{pq,\kappa_i} + A^T_{qpr,\kappa_i}}{2} \left[ \sum_{g \in \mathcal{g}(\mathcal{r}_{k+i})} \pi_{r_k+I} \mathcal{P}_{wv}(g) + (1 - \pi_{\mathcal{r}}(r_{k+i})) \mathcal{P}_{wv}(l) \right] + A_{pq,\kappa_i} + A_{qpr,\kappa_i} - \mathcal{P}_{pj}(r_{k+i}) + \beta F_r(r_{k+i})^T RF_p(r_{k+i}) + \beta Q - \beta \tilde{c}_{k+i} I \leq 0,
\]

where $\tilde{c}_k$ is the minimum term of $c_{k+i}, i \in [0, P]$. Substituting $\mathcal{P}_{pq}(r_k) = q^T \mathcal{O}_{pq}(r_k) \mathcal{O}_{pq}(r_k), \mathcal{O}_{pq}(r_k) > 0$, using Schur complement, and then pre- and postmultiplying the above inequality by $\text{diag}([\mathcal{O}_{pq} \mathcal{H}_1, \mathcal{O}_{wv} \mathcal{H}_2, \ldots], \mathcal{O}_{wv} \mathcal{H}_g)$, we can see that this is equivalent to

\[
\begin{bmatrix}
\mathcal{O}_{pq}(r_{k+i}) & * & * & * \\
\beta^{1/2} \mathcal{O}_{pq}(r_{k+i}) & M_{pq}(r_{k+i}) & N_{wv} & * \\
\beta^{1/2} R^{1/2} F_p(r_{k+i}) & \mathcal{O}_{pq}(r_{k+i}) & 0 & 0 & \gamma I \\
\end{bmatrix} \geq 0,
\]

\[
\forall i \in P, p, q, w \in S, j, v \in L, r_{k+i} \in \mathcal{J}, g \in \mathcal{J}_{\kappa_i}.
\]

Then, (34) is satisfied for all $i \in P$ if

\[
\frac{\mathcal{A}^T_{pq,\kappa_i} + \mathcal{A}^T_{qpr,\kappa_i}}{2} \left[ \sum_{g \in \mathcal{g}(\mathcal{r}_{k+i})} \pi_{r_k+I} \mathcal{P}_{wv}(g) + (1 - \pi_{\mathcal{r}}(r_{k+i})) \mathcal{P}_{wv}(l) \right] - \mathcal{P}_{pj}(r_{k+i}) + \beta F_r(r_{k+i})^T RF_p(r_{k+i}) + \beta Q - \beta \tilde{c}_{k+i} I \leq 0,
\]

with

\[
M_{pq}(r_{k+i}) \equiv \left[ \sqrt{\pi_{\mathcal{r}_k+I} E_{pq}(r_{k+i})}, \ldots, \sqrt{\pi_{\mathcal{r}_k=I} E_{pq}(r_{k+i})} \right]^T,
\]

\[
N_{wv} \equiv \text{diag}([\mathcal{O}_{wv} \mathcal{H}_1, \mathcal{O}_{wv} \mathcal{H}_2, \ldots], \mathcal{O}_{wv} \mathcal{H}_g),
\]

\[
E_{pq}(r_{k+i}) \equiv (A_{pq,\kappa_i} + B_{pq,\kappa_i} F_p(r_{k+i})) \mathcal{O}_{pj}(r_{k+i}) + \mathcal{A}_{pq,\kappa_i} + B_{pq,\kappa_i} F_p(r_{k+i}) \mathcal{O}_{pj}(r_{k+i}) \times 2^{-1}.
\]

Inequality (37) is affine in $[A_{pq}(k+i, r_k), B_{pq}(k+i, r_k)]$. Following the logic of de Oliveira, Bernussou and Geromel [35], and Cuzzola et al. [20], (37) is satisfied for all

\[
[A_{pq,\kappa_i} B_{pq,\kappa_i}] \in \Omega_p(r_k)
\]

if and only if there exist $G > 0, Y_p(r_k) = F_p(r_k) G$, and a positive $\gamma$ such that

\[
\begin{bmatrix}
G + G^T - \mathcal{O}_{pq}(r_{k+i}) & * & * & * \\
\mathcal{M}_{pq,fo}(r_{k+i}) & N_{wv} & * & * \\
\beta^{1/2} (Q - \tilde{c}_{k+i} I)^{1/2} \mathcal{O}_{pq}(r_{k+i}) & 0 & \gamma I & * \\
\beta^{1/2} R^{1/2} F_p(r_{k+i}) & \mathcal{O}_{pq}(r_{k+i}) & 0 & 0 & \gamma I \\
\end{bmatrix} \geq 0,
\]

\[
\forall i \in P, p, q, w \in S, j, v \in L, r_{k+i} \in \mathcal{J}, g \in \mathcal{J}_{\kappa_i}.
\]
with
\[
\hat{M}_{pqfo}(r_{ki}) \triangleq \left[ \sqrt{\pi r_{ki}} E_{pqfo}(r_{ki}), \ldots, \sqrt{1-\pi r_{ki}} E_{pqfo}(r_{ki}) \right]^T,
\]
\[
N_{wr} \triangleq \text{diag}\left\{ \theta_{wr}(\mathcal{H}_1), \theta_{wr}(\mathcal{H}_2), \ldots, \right\},
\]
\[
\hat{E}_{pqfo}(r_{ki}) \triangleq \left( A_{pqfo} G + B_{pqfo} Y_q(r_{ki}) \right) + A_{pqfo} G + B_{pqfo} Y_q(r_{ki})
\]
\[
\times 2^{-1}.
\]
The feedback matrix is then given by \( F_p(r_{ki}) = Y_p(r_{ki}) G^{-1} \).

**Remark 3.** Based on the above analysis, we can see that the choice of control horizon \( M \) amount to the choice of series \( \tilde{c}_k \). That is, given a constant control horizon \( M \), we can construct some infinite convergent series whose corresponding series \( \tilde{c}_k \) possess some properties, such as \( \tilde{c}_k = 1/(k+1)^2 \). Therefore, we will discuss neither the control horizon \( M \) nor the predictive horizon \( P \) which is supposed to be equal to \( M \).

**Remark 4.** In particular, when the control horizon \( M = \infty \), the conditions for the above derivation can be satisfied if and only if the series \( \tilde{c}_k = 0, k \geq 0 \). Then it follows that the method is equivalent to the approach in [20] (modified in [22]).

### 3.3. Minimization of the Upper Bound with Input and Output Constraints

**Theorem 5.** Consider the closed-loop uncertain system (12) with the polytopic uncertainty set \( \Omega(p, r_k) \), \( p \in \mathbb{S}, r_k \in \mathcal{J} \). Let \( x(k) = x(k | k) \) be the state measured at sampling time \( k \), and \( \theta_{r_i}(r_k) > 0 \), for all \( p \in \mathbb{S}, j \in \mathbb{L}, r_k \in \mathcal{J} \). The constraints on the control input and plant output in the form of (17) can be transferred into problems expressed by the following linear matrix inequalities, respectively:

\[
\begin{bmatrix}
\begin{array}{c}
u^2_{\max} L
\end{array}
\end{bmatrix}
\begin{bmatrix}
Y_p(\text{r}_{\text{ki}})
Y^T_p(\text{r}_{\text{ki}})
\end{bmatrix}
\geq 0,
\]
\[
\forall p \in \mathbb{S}, j \in \mathbb{L}, r_{ki} \in \mathcal{J},
\]
\[
\begin{bmatrix}
X
\end{bmatrix}
\begin{bmatrix}
Y_p(\text{r}_{\text{ki}})
Y^T_p(\text{r}_{\text{k}+i})
\end{bmatrix}
\geq 0,
\]
\[
\forall p \in \mathbb{S}, j \in \mathbb{L}, r_{ki} \in \mathcal{J},
\]
Using the similar logic in [35], (46) is proved equivalent to (42). The proof of (43)-(44), which can be achieved by an analogous argument, is omitted for the sake of brevity. □

Remark 6. The obtained theorems can be easily reduced to simple situations, for example, fuzzy systems with uncertainties and Markov jump systems, and can be solved via commercial solvers such as LMI TOOL, YALMIP, and GloptiPoly.

4. Numerical Simulation

In this section, we present a numerical example that clearly illustrates the improvement obtained with Theorem 2. We will compare under different situations the improved method with the approach in [20] (modified in [22]) which can be seen as $\hat{c}_k = 0, k > 0$ and $\beta = 1$. Consider the single pendulum system:

$$
\dot{x}_1(t) = x_2(t),
$$

$$
\dot{x}_2(t) = -c_{1j} \sin(x_1(t)) + c_{2j} x_2(t) + u(t) + 0.1 w(t),
$$

(47)

where $x_1(t)$ is the angular displacement, $x_2(t)$ is the angular velocity, $u(t)$ is the control torque, $w(t)$ is the disturbance, and $c_{1j}$ and $c_{2j}$ are jump parameters with values $c_{11} = 1, c_{12} = 2, c_{13} = 0.5, c_{21} = 1, c_{22} = 0.5$, and $c_{23} = 2$. The angular displacement $x_1(t)$ is assumed to vary in the intervals $[-\pi/2, \pi/2]$. This system can be represented as the following discrete-time fuzzy model with partly unknown transition probabilities:

$$
\Pi = \begin{bmatrix}
0 & 0.4 & 0.25 \\
0.9 & 0 & 0.4 \\
0.35 & 0.5 & 0.35
\end{bmatrix}.
$$

(48)

Set $x(k) = [x_1(k) \ x_2(k)]^T$, and choose the membership functions as

$$
h_1(x_1(k)) = \frac{4x_1^2(k)}{\pi^2},$$

$$
h_2(x_1(k)) = 1 - h_1(x_1(k)).
$$

(49)

For the sake of simplicity, we use two T-S fuzzy rules to approximate this system.

Plant Rule 1. If $x_1(k)$ is about $\pi/2$, then

$$
x(k + 1) = A_1(r_k) x(k) + B_1(r_k) u(k),$$

$$
y(k) = C_1(r_k) x(k).
$$

(50)

Plant Rule 2. If $x_1(k)$ is about $-\pi/2$, then

$$
x(k + 1) = A_2(r_k) x(k) + B_2(r_k) u(k),$$

$$
y(k) = C_2(r_k) x(k).
$$

(51)

where

$$
A_1(r_k) \in \Omega(1,1), \quad B_1(r_k) = [0 \ T]^T,$$

$$
C_1(r_k) = \begin{bmatrix} 1 \\ -0.4530 T \ 1+0.7116 T \end{bmatrix},$$

$$
\Omega(1,1) = \left\{ \begin{bmatrix} T \\ 1+0.2T \ 1+0.7116T \end{bmatrix}, \begin{bmatrix} T \\ 1+0.3530T \ 1+0.7116T \end{bmatrix} \right\},$$

$$
\Omega(2,1) = \left\{ \begin{bmatrix} 1 \\ T \ T \end{bmatrix}, \begin{bmatrix} 1+0.2T \\ -0.9T \ 1+T \end{bmatrix} \right\},$$

$$
\Omega(1,2) = \left\{ \begin{bmatrix} T \\ -0.9060T \ 1+0.768T \end{bmatrix}, \begin{bmatrix} T \\ -0.8060T \ 1+0.768T \end{bmatrix} \right\},$$

$$
\Omega(2,2) = \left\{ \begin{bmatrix} 1 \\ -2T \ 1+0.5T \end{bmatrix}, \begin{bmatrix} 1+0.2T \\ -1.9T \ 1+0.5T \end{bmatrix} \right\},$$

$$
\Omega(1,3) = \left\{ \begin{bmatrix} T \\ -0.2265T \ 1+1.8558T \end{bmatrix}, \begin{bmatrix} T \\ -0.1265T \ 1+1.8558T \end{bmatrix} \right\},$$

$$
\Omega(2,3) = \left\{ \begin{bmatrix} T \\ -0.5T \ 1+2T \end{bmatrix}, \begin{bmatrix} T \\ -0.4T \ 1+2T \end{bmatrix} \right\}.
$$

(52)

Our purpose here is to illustrate the advantages of the proposed method by comparing the optimal parameter $\gamma$ for different situations. First of all, supposing $\hat{c}_k = 1/(k+1)^2$, $\beta = 0.5$, and the initial states $x(0) = [3\pi/8; 0.5]$, the steady-state responses of the closed-loop fuzzy MJS with input constraints $\|u(k+i | k)\|_2 \leq 3, k > 0, i \in \mathbb{N}$, are shown in Figure 1. Meanwhile, the optimal results of $\gamma$ compared for different initial conditions are shown in Table 1. One may note that the average values of $\gamma$ become much smaller when the additional parameters $\hat{c}_k$ and $\beta$ are introduced. Then, assuming initial states $x(0) = [\pi/4; 0.5]$, $\beta = 0.5$, we can obtain the corresponding values of $\gamma$ for different $\hat{c}_k$ listed in Table 2. In the same way, by assuming initial states $x(0) = [\pi/4; 0.5]$, $\hat{c}_k = 1/(k + 1)^2$, the information about $\gamma$ for different values of $\beta$ is given in Table 3. It is easy to observe from Tables 2 and 3 that the optimal performance is closely related to the two parameters.
Figure 1: (a) State response of MJS system with $x(0) = [3\pi/8; 0.5]$ and $\tilde{c}_k = 1/(k+1)^2$, and $\beta = 0.5$ for case 1, $\tilde{c}_k = 0$, $\beta = 1$ for case 2. (b) Input signals obtained based on Theorem 2.

5. Conclusion

In this paper, the problem of controller design based on MPC algorithm for uncertain systems is discussed. A relaxed scheme which has less conservativeness than traditional approaches is derived through introducing two additional parameters. Based on this scheme, a new set of criteria for model predictive controller design is obtained based on the fuzzy Markov jump system with partially unknown TPMs in an arbitrarily large horizon. A practical example is presented to show the effectiveness and applicability of the developed method. It is expected that the methods and ideas behind the paper could be extended to other systems or issues, such as filter design for the underlying system.
Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
