This paper investigates the robust finite-time control problem for flexible spacecraft attitude tracking maneuver in the presence of model uncertainties and external disturbances. Two robust attitude tracking controllers based on finite-time second-order sliding mode control algorithms are presented to solve this problem. For the first controller, a novel second-order sliding mode control scheme is developed to achieve high-precision tracking performance. For the second control law, an adaptive-gain second-order sliding mode control algorithm combining an adaptive law with second-order sliding mode control strategy is designed to relax the requirement of prior knowledge of the bound of the system uncertainties. The rigorous proofs show that the proposed controllers provide finite-time convergence of the attitude and angular velocity tracking errors. Numerical simulations on attitude tracking control are presented to demonstrate the performance of the developed controllers.

1. Introduction

In recent years, considerable attention has been focused on spacecraft attitude control problems. Attitude control systems are required to offer the present generation of spacecraft with attitude maneuver, tracking, and pointing capabilities. Since the attitude dynamics of spacecraft is coupled and highly nonlinear, the attitude controller designs are usually difficult. Besides, the effect of motion of the elastic appendages makes the control problem more complicated. In the absence of external disturbances, the modal-independent proportional-derivative (PD) controller proposed in [1] can achieve asymptotical stability of both the attitude and angular velocity. In practical situations, the model parameters of the spacecraft may not be exactly known and the spacecraft is always subject to external disturbances. Thus, the attitude control problem with uncertainties and external disturbance has also attracted a great deal of attention. Various nonlinear robust control approaches [2–4] have been proposed for solving the attitude tracking control problem of flexible spacecraft. These control schemes include adaptive control [5, 6], sliding mode control [7, 8], output feedback control [9, 10], optimal control [11, 12], and intelligent control [13].

Among these methods, sliding mode control (SMC) has been shown to be a potential approach when applied to a system with disturbances which satisfy the matched uncertainty condition [14]. Robust attitude controllers of flexible spacecraft based on the SMC scheme have been proposed in [15, 16]. These control laws can achieve global asymptotic stability and provide good tracking results. However, these controllers were designed based on an asymptotic stability analysis which implies that the system trajectories converge to the equilibrium with infinite settling time. It is well known that finite-time stabilization of dynamical systems may provide a faster disturbance attenuation besides giving faster convergence to the required orientation. A recently developed technique for finite-time stabilization is the terminal sliding mode (TSM) method [17, 18] which can be used to design a controller that will guarantee a finite-time convergence to the origin. In [19, 20], the attitude motion of flexible spacecraft has been studied and the TSM method was used to design finite-time controllers.
However, the TSM method usually provides lower tracking precision when compared with second-order sliding mode control (SOSMC) schemes [21, 22]. This technique preserves the robustness ability of SMC and also yields improved accuracy and performance. Various real-life applications have been controlled in a practical implementation of SOSMC schemes (e.g., see [23–25]). The SOSMC strategies have been successfully applied to attitude tracking controller designs for a rigid spacecraft in [26, 27], but these schemes have been rarely used for attitude tracking control of flexible spacecraft.

In this paper, by virtue of SOSMC designs, the proposed attitude tracking control laws can guarantee the convergence of attitude tracking errors in finite-time. First, a novel finite-time SOSMC scheme is designed to achieve fast and accurate tracking responses. Next, to obtain the second control law, we combine the adaptive law with the SOSMC scheme proposed in [27]. This controller relaxes the requirement of prior knowledge on the bound of uncertainties. With the time scaling approach [28], the control parameters can be tuned by using only one variable.

The main contributions of this paper are as follows.

(I) Robust finite-time control algorithms based on SOSMC schemes have been rarely studied for attitude tracking maneuver of a flexible spacecraft. The finite-time stability of the proposed control laws is analyzed using Lyapunov stability concepts.

(II) A novel adaptive law for the gains of the SOSMC algorithm has been rarely developed by using the time scaling approach. The presented control method does not need a priori knowledge of the uncertainty and disturbance bounds.

This paper is organized as follows. In Section 2, the dynamic and kinematic equations governing the attitude model [29, 30] are described and the control design problem is formulated. Section 3 presents a novel SOSMC control algorithm for a flexible spacecraft. The sliding manifold is chosen and the sliding control law is studied and a proof of finite-time convergence of this controller is given. Section 4 proposes an adaptive-gain SOSMC law. The stability of the closed-loop system is analyzed. A numerical example of spacecraft tracking maneuvers is presented in Section 5 to verify the usefulness of the proposed controllers. In Section 6, we present conclusions.

2. Nonlinear Mode and Problem Formulation

2.1. Spacecraft Attitude Dynamics and Kinematics. The unit quaternion is adopted to describe the attitude of the spacecraft for global representation without singularities [29]. The unit quaternion \( q \) is defined by

\[
q = \begin{bmatrix} n \sin \left( \frac{\phi}{2} \right) \\ \cos \left( \frac{\phi}{2} \right) \end{bmatrix} = \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix},
\]

where \( n \in \mathbb{R}^3 \) is a unit vector called the Euler axis, \( \phi \in \mathbb{R} \) denotes the magnitude of Euler axis rotation and \( q_4 \in \mathbb{R} \) are the vector components and the scalar of the unit quaternion, respectively. They are subject to the constraint \( q^T q + q_4^2 = 1 \). Consider the first time derivative of \( q \). The kinematic equations are given by [29, 30]

\[
\dot{q} = \frac{1}{2} (q_4 I_3 + q^T) \omega,
\]

(2)

where \( I_3 \) is a 3×3 identity matrix, and \( q^T \) is a skew-symmetric matrix:

\[
q^T = \begin{bmatrix} 0 & -q_3 & q_2 \\ q_3 & 0 & -q_1 \\ -q_2 & q_1 & 0 \end{bmatrix}.
\]

(3)

2.2. Relative Attitude Error Kinematics. We explain briefly the attitude error using quaternions. We define here the desired quaternion \( Q_0 = [q_{1r}^T \ q_{3r}]^T \in \mathbb{R}^3 \times \mathbb{R} \) with \( q_{1r} = [q_{1r} \ q_{2r} \ q_{3r}]^T \). Also the attitude error \( q_e = [q_{1e}^T \ q_{3e}]^T \in \mathbb{R}^3 \times \mathbb{R} \) with \( q_{1e} = [q_{1e} \ q_{2e} \ q_{3e}]^T \). Using the quaternion multiplication law, we obtain

\[
Q_e = \begin{bmatrix} q_0 q - q_4 q_1 - q_e^T q \\ q_0 q_4 + q^T q_e \end{bmatrix}
\]

subject to the constraint

\[
Q_e^T q_e = (q^T q + q_4^2) (q^T q + q_4^2) = 1.
\]

(5)

The kinematic equation for the attitude error is expressed as [29, 30]

\[
\dot{Q}_e = \frac{1}{2} \begin{bmatrix} q_e^T + q_4 I_{3	imes 3} \\ -q_e^T \end{bmatrix} \omega_e.
\]

(6)

2.3. Flexible Spacecraft Dynamics. The equation governing a flexible spacecraft is expressed as [3]

\[
J \dot{\omega} + \delta^\top \hat{\eta} = -\omega^\top (J \omega + \delta^\top \hat{\eta}) + u + d,
\]

(7)

\[
\dot{\hat{\eta}} + C \hat{\eta} + K \eta = -\delta \dot{\omega},
\]

where \( J = J^T \in \mathbb{R}^{3\times 3} \) is the total inertia matrix of the spacecraft, \( \eta \in \mathbb{R}^3 \) is the modal displacement, and \( \delta \in \mathbb{R}^{4\times 3} \) is the coupling matrix between the central rigid body and the flexible attachments. \( \omega = [\omega_1 \ \omega_2 \ \omega_3]^T \in \mathbb{R}^3 \) represents the angular velocity vector and \( \omega^\top \) is a skew-symmetric matrix with a formula similar to \( q^T \). \( u = [u_1 \ u_2 \ u_3]^T \in \mathbb{R}^3 \) is the control input, \( d = [d_1 \ d_2 \ d_3]^T \in \mathbb{R}^3 \) represents the external disturbance torque, and \( K \) and \( C \) denote the stiffness and damping matrices, respectively, which are defined as

\[
K = \text{diag} (\omega_{n_{i}}, i = 1, 2, \ldots , N),
\]

(8)

\[
C = \text{diag} (2\xi_i \omega_{n_{i}}, i = 1, 2, \ldots , N)
\]

with damping \( \xi_i \) and natural frequency \( \omega_{n_{i}} \).
If terms $\delta^T \dot{\eta}$ and $\omega^x \delta^T \dot{\eta}$ are considered as lumped perturbations to rigid body dynamics, (7) can be obtained as

$$J \ddot{\omega} = -\omega^x J \dot{\omega} + \dot{\omega} + \Delta f(\eta, \dot{\eta}, \omega),$$  \hfill (9)

where $\Delta f(\eta, \dot{\eta}, \omega) = -\delta^T \dot{\eta} - \omega^x \delta^T \dot{\eta}$ may be considered as the lumped perturbation. Let the angular velocity error be defined as $\omega_e = \omega - \omega^d$; then the error dynamics are given by

$$J \ddot{\omega}_e = -(\omega_e + \omega^d)^T J (\omega_e + \omega^d) - J \dot{\omega}_d + u + T_d,$$  \hfill (10)

where $T_d = \dot{\omega} + \Delta f(\dot{\eta}, \ddot{\eta}, \omega)$.

Using (6), one has

$$\ddot{q}_e = \Xi(q_e, q\omega_e) \omega_e$$  \hfill (11)

with $\Xi(q_e, q\omega_e) = (1/2)(q_e^2 + q\omega_e^2)$.

Define $P \triangleq \Xi^{-1}$ and $J^* \triangleq P^T J P$ and consider the time derivative of (11). One can obtain [3]

$$J^* \ddot{q}_e + C^* \dot{q}_e + N^* = \tau_u + \tau_d,$$  \hfill (12)

where

$$C^* = -J^* P^{-1} P - 2P^T (JP\dot{q}_e)^* P, \quad \tau_u = \frac{1}{2} P^T \tau_u, \quad \tau_d = \frac{1}{2} P^T \tau_d,$$

$$N^* = P^T \left[(P\dot{q}_e)^* \dot{\omega}_d + P^T \left[(\dot{\omega}_d)^* JP\dot{q}_e \right] \right] + \frac{1}{2} P^T \dot{\omega}_d. $$  \hfill (13)

Throughout the remainder of this paper, the following are assumed.

**Assumption 1.** The elastic oscillation and its rate are supposed to be bounded; that is to say, $\|p(t)\|$ and $\|\dot{p}(t)\|$ are bounded during the whole attitude tracking process.

Let $x_1 = q_e$ and $x_2 = \dot{q}_e$; the spacecraft model (12) can be written as

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = F + B_0 u + \ddot{d},$$  \hfill (14)

where $F = -J^* (C^* x_2 + N^*)$, $B_0 = (1/2)(P^T J P)^{-1} P^T$, and $\ddot{d} = (P^T J P)^{-1}\tau_d$.

**Assumption 2.** The first time derivative of the disturbance vector $\ddot{d}$ to the spacecraft system in (12) is assumed to be bounded and it satisfies the following condition:

$$\left|\ddot{d}_i(t)\right| \leq \varrho, $$  \hfill (15)

where $\varrho$ is a positive constant.

### 2.4. Problem Statement

In this work, we consider tracking maneuvers. The control objective is to realize desired rotations of flexible spacecraft in the presence of external disturbances. In other words, we shall find a controller $u$ subject to (14) such that, for all initial conditions, the desired rotations are achieved as follows:

$$\lim_{t \to T} q_{ce} = 0, \quad \lim_{t \to T} q_{ce} = 1, \quad \lim_{t \to T} \omega_e = 0,$$  \hfill (16)

where $T$ is a positive constant. Note that, when $q_{ce} \to 0$, we have $q_{ce} \to 1$, due to the constraint relation (5).

### 2.5. Finite-Time Stability

We now restate the concepts related to finite-time stability [31, 32].

*Definition 3* (see [31]). Consider a time invariant system in the form of

$$\dot{x} = f(x), \quad f(0) = 0, \quad x \in \mathbb{R}^n,$$  \hfill (17)

where $f : \hat{U}_0 \to \mathbb{R}^n$ is continuous on an open neighborhood $\hat{U}_0$ of the origin. The equilibrium $x = 0$ of the system (17) is (locally) finite-time stable if (i) it is Lyapunov stable, in the sense that, when $x \to 0$, there is a settling time $T > 0$, such that every solution $x(t, x_0)$ of the system (17) is defined with $x(t, x_0) \in \hat{U}[0]$ for $t \in [0, T]$ and it satisfies

$$\lim_{t \to T(x_0)} x(t, x_0) = 0$$  \hfill (18)

and $x(t, x_0) = 0$ if $t \geq T$. Moreover, if $\hat{U} = \mathbb{R}^n$, the origin is globally finite-time stable.

*Definition 4.* Consider a controlled system

$$\dot{x} = f(x) + g(x) u, \quad x \in \mathbb{R}^n, u \in \mathbb{R}^m$$  \hfill (19)

with $g(x) \neq 0$. It is finite-time stabilizable if there is a feedback law $u(x)$ such that $x = 0$ is a (locally) finite-time stable equilibrium of closed-loop system.

*Lemma 5* (see [32]). Suppose that the origin is a finite-time stable equilibrium of (17) and the settling time function $T_f$ is continuous at zero, where $f(\cdot)$ is continuous. Let $\hat{U}$ be defined as in Definition 3 and let $i \in (0, 1)$. There exists a continuous scalar function $V$ such that (i) $V$ is positive definite and (ii) $V$ is real valued and continuous on $\hat{U}$ and there exists $c \in \mathbb{R}^+$ such that

$$V + cV^i \leq 0, \quad \text{for any } i \in (0, 1).$$  \hfill (20)

*Lemma 6* (Feng et al. [18]). For any numbers $\lambda_1 > 0, \lambda_2 > 0$, and $0 < \omega < 1$, an extended Lyapunov contion of finite-time stability can be given in the form of fast terminal sliding mode as

$$\dot{V}(x) + \lambda_1 V(x) + \lambda_2 V^\omega(x) \leq 0,$$  \hfill (21)

where the settling time can be estimated by

$$T_s \leq \frac{1}{\lambda_1 (1 - \omega)} \ln \frac{\lambda_1 V^{1 - \omega}(x_0) + \lambda_2}{\lambda_2}.$$  \hfill (22)
3. SOSMC Algorithm

In this section, a novel SOSMC algorithm is proposed to accomplish attitude tracking control of a flexible spacecraft. Under Assumptions 1 and 2, this control scheme is designed such that the attitude tracking error $q_e$ and the angular velocity error $\omega_e$ approach zero in finite time although uncertainties and external disturbances are taken into account. This new SOSMC law is achieved by a Lyapunov function approach, so the finite-time stability of the closed-loop system of the spacecraft model (14) is ensured. The goal is to enforce the sliding mode on the manifold

$$ S = x_2 + \kappa x_1, $$

where $S = [S_1 \ S_2 \ S_3]^T \in \mathbb{R}^3$ and $\kappa$ is a positive constant. From (23), the first time derivative of $S$ is obtained as

$$ \dot{S} = \dot{x}_2 + \kappa \dot{x}_1, $$

$$ = F + B_0 u + \tilde{d} + \kappa x_2. \quad (24) $$

Then, it is followed by choosing a SOSMC law to force the system trajectory onto the sliding surface. Let $s_1 = S$ and $s_2 = \dot{S}$; the proposed control law is defined as

$$ u = (B_0)^{-1} \left( -F - \kappa x_2 - \mu_1 \text{sign}^\alpha(s_1) - \mu_2 s_1 \right. $$

$$ \left. - \int_0^t (\mu_3 \text{sign}^\alpha(s_2(\tau)) + \mu_4 s_2(\tau)) \, d\tau \right), \quad (25) $$

where $0 < \alpha < 1$. The gain matrices $\mu_1 = \text{diag}(\mu_{11}, \mu_{12}, \mu_{13})$, $\mu_2 = \text{diag}(\mu_{21}, \mu_{22}, \mu_{23})$, $\mu_3 = \text{diag}(\mu_{31}, \mu_{32}, \mu_{33})$, and $\mu_4 = \text{diag}(\mu_{41}, \mu_{42}, \mu_{43})$, with $\mu_{ij}, \mu_{ij}, \mu_{ii}$, and $\mu_{ij}$ ($i = 1, 2, 3$), are positive gains. The function $\text{sign}^\alpha(y)$ is defined as

$$ \text{sign}^\alpha(y) = \left[ |y_1|^\alpha \text{sign}(y_1) \ |y_2|^\alpha \text{sign}(y_2) \ |y_m|^\alpha \text{sign}(y_m) \right]^T $$

(26) with $0 < \alpha < 1$ and $y \in \mathbb{R}^m$.

Substituting (25) into (24), the closed-loop dynamics is obtained as

$$ \dot{s}_1 = \mu_1 \text{sign}^\alpha(s_1) - \mu_2 s_1 $$

$$ - \int_0^t (\mu_3 \text{sign}^\alpha(s_2(\tau)) + \mu_4 s_2(\tau)) \, d\tau + \tilde{d}. \quad (27) $$

Let $\tilde{\delta}_1(t) = \delta_1(t), \ z_{1i} = s_1, \text{and} \ z_{2i} = -\int_0^t (\mu_3 \text{sign}^\alpha(s_2(\tau)) - \mu_4 s_2(\tau)) \, d\tau - \tilde{d}$. The system (27) can be written in scalar form ($i = 1, 2, 3$) as

$$ \dot{z}_{1i} = -\mu_{1i} |z_{1i}|^\alpha \text{sign}(z_{1i}) + z_{2i} - \mu_2 z_{1i}, $$

$$ \dot{z}_{2i} = -\mu_{2i} |z_{2i}|^\alpha \text{sign}(z_{2i}) - z_{2i} - \mu_4 z_{1i} + \delta_1. \quad (28) $$

Next, the proof of finite-time convergence to the origin is given.

\textbf{Theorem 7.} Under Assumptions 1 and 2 and the action of the control law (25), the state trajectories $z_{1i}, z_{2i}, \text{and} z_{2i}$ converge in finite time to the region

$$ \|e\| \leq \Delta = \min \{\Delta_1, \Delta_2\}, $$

$$ \Delta_1 = \frac{2\varepsilon_1}{\varepsilon_2}, \quad \Delta_2 = \sqrt{2} \left(\frac{\sqrt{2\varepsilon_1}}{\varepsilon_1}\right)^{1/\alpha}, \quad (29) $$

where $\varepsilon = [z_{1i} \ z_{2i}]^T$ and $\Delta_1, \Delta_2 > 0$ are the results from the chosen gains.

\textbf{Proof.} We choose the Lyapunov function $V_1 = (1/2)\varepsilon^2$ for analyzing the closed-loop system dynamics of (28). The time derivative of $V_1$ is given by

$$ \dot{V}_1 = z_{1i} \left( -\mu_{1i} |z_{1i}|^\alpha \text{sign}(z_{1i}) + z_{2i} - \mu_2 z_{1i} \right. $$

$$ \left. + z_{2i} \left( -\mu_{2i} |z_{2i}|^\alpha \text{sign}(z_{2i}) - z_{2i} - \mu_4 z_{2i} + \delta_1 \right) \right) $$

$$ = -\mu_{1i} |z_{1i}|^{\alpha+1} - \mu_{2i} z_{1i} - \mu_4 z_{2i} + \delta_1, \quad (30) $$

which can be further written as

$$ \dot{V}_1 = -\mu_{1i} \left( |z_{1i}|^{\alpha+1} - |z_{2i}|^{\alpha+1} \right) - \mu_{2i} (z_{1i}^2 + z_{2i}^2) + \delta_1, \quad (31) $$

$$ -\mu_{4i} z_{2i}^2 + \|e\|. $$

where $\mu_{1i} = \min(\mu_{11}, \mu_{12}, \mu_{13})$, $\mu_{2i} = \min(\mu_{21}, \mu_{22}, \mu_{23})$, $\mu_{3i} = \min(\mu_{31}, \mu_{32}, \mu_{33})$, and $\mu_{4i} = \min(\mu_{41}, \mu_{42}, \mu_{43})$, one obtains

$$ \dot{V}_1 \leq -\bar{\mu} \left( |z_{1i}|^{\alpha+1} + |z_{2i}|^{\alpha+1} \right) - \bar{\mu}_{2i} (z_{1i}^2 + z_{2i}^2) + \varepsilon \|e\| $$

$$ \dot{V}_1 \leq -\bar{\mu}_{2i} \frac{2(\alpha+1)}{2} \frac{1}{\alpha+1/2} - 2\bar{\mu}_{2i} V_1 + \sqrt{2\varepsilon_1} \sqrt{V_1}. \quad (32) $$

Letting $\varepsilon_1 = \bar{\mu}_{1i} / 2^{\alpha+1/2}$ and $\varepsilon_2 = 2 \bar{\mu}_{2i}$, we can change (32) into the following forms:

$$ \dot{V}_1 \leq -\left( \varepsilon_2 - \sqrt{\frac{2\varepsilon_1}{\varepsilon_1}} \right) V_1 - \varepsilon_1 V_1^{\alpha+1/2}, \quad (33) $$

$$ \dot{V}_1 \leq -\varepsilon_2 V_1 - \left( \varepsilon_1 - \frac{\sqrt{2\varepsilon_1}}{\sqrt{\varepsilon_1}} \right) V_1^{\alpha+1/2}. \quad (34) $$

From (33), if $\varepsilon_2 - \sqrt{2\varepsilon_1}/\sqrt{V_1} > 0$ then the finite-time stability is still ensured, and hence, by Lemma 5, the state trajectories $z_{1i}$ and $z_{2i}$ of the system (28) converge to the region

$$ \|e\| \leq \frac{2\varepsilon_2}{\varepsilon_1} \quad (35) $$

in finite time. From (33), if $\varepsilon_1 - \sqrt{2\varepsilon_1}/\sqrt{V_1} > 0$, then the finite-time stability is still ensured, and hence, by Lemma 5, the state trajectories $z_{1i}$ and $z_{2i}$ of the system (28) converge to the region

$$ \|e\| \leq \sqrt{2} \left(\frac{\sqrt{2\varepsilon_1}}{\varepsilon_1}\right)^{1/\alpha}, \quad (36) $$
in finite time. Therefore, the state trajectories $z_{1i}$ and $z_{2i}$ of the system (28) converge in finite-time to the region
\[
\|z\| \leq \Delta = \min \{\Delta_1, \Delta_2\},
\]
where $\Delta_1 = 2q/e_2$ and $\Delta_2 = \sqrt{2(\sqrt{2q/e_1})(1/\epsilon_1)}$.  

Remark 8. The accuracy of tracking errors $z_{1i}$ and $z_{2i}$ is determined by the control parameters $\mu_{ti}, \mu_{ti}, \mu_{3i}$, and $\mu_{4i}$, $i = 1, 2, 3$. To obtain the desired accuracy, it is necessary to reduce the size of the region (37) by increasing the values of the control parameters $\mu_{ti}, \mu_{3i}, \mu_{4i}$, and $\mu_{4i}$. However, using large values of these parameters leads to high magnitudes of control torques.

4. Adaptive-Gain SOSMC Algorithm

Next, the proposed adaptive-gain SOSMC scheme is designed by modifying the smooth SOSMC law presented in [27]. In stead of using the constant controller gains as presented in [27], the adaptive gains are considered in this paper. A novel adaptive law to tune these gains is presented. The main advantages of the proposed method are that only one parameter has to be tuned and this method relaxes the requirement of prior knowledge of the bound of system uncertainties.

The proposed control law is given by
\[
u = B_0^{-1} \left(-F - \kappa x_2 - \lambda (t) \text{sign}(t^{p-1}/p) (S) - e(t) S - \alpha(t) \int_0^t \text{sign}(t^{p-2}/p) (S(\tau)) d\tau - K(t) \int_0^t S(\tau) d\tau\right),
\]
where $p > 2$ and the adaptive gains $\lambda(t), \alpha(t), e(t)$, and $K(t)$ are the design parameters defined as
\[
\lambda(t) = \lambda_0 \text{diag} \left(L(t)^{(p-1)/p} (t), L(t)^{(p-1)/p} (t), L(t)^{(p-1)/p} (t)\right),
\]
\[
\alpha(t) = \alpha_0 \text{diag} \left(L(t), L(t), L(t)\right),
\]
\[
e(t) = e_0 \text{diag} \left(L(t), L(t), L(t)\right),
\]
\[
K(t) = K_0 \text{diag} \left(L_2(t), L_2(t), L_2(t)\right)
\]
with $\lambda_0, \alpha_0, e_0, K_0$ being positive constants. The adaptive law of the time-varying function $L(t)$ is given by
\[
L(t) = \begin{cases} 1, & \text{for } |S| \neq 0, \\ 0, & \text{for } |S| = 0, \end{cases}
\]
where $l$ and the initial value $L(0)$ are positive constants. Substituting (38) into (14), we obtain
\[
\dot{S} = -\lambda(t) \text{sign}(t^{p-1}/p) (S) - e(t) S - \alpha(t) \int_0^t \text{sign}(t^{p-2}/p) S(\tau) d\tau - K(t) \int_0^t S(\tau) d\tau + \tilde{d}.
\]
Next, the same procedure as presented in Section 3 is recalled. We can have the scalar form of (41) as
\[
\dot{\tilde{z}}_i = -\lambda(t) |\tilde{z}_{1i}|^{(p-1)/p} \text{sign}(|\tilde{z}_{1i}|) - e(t) \tilde{z}_{1i} + \tilde{z}_{2i},
\]
\[
\dot{\tilde{z}}_i = -\alpha(t) |\tilde{z}_{1i}|^{(p-2)/p} \text{sign}(|\tilde{z}_{1i}|) - K(t) \tilde{z}_{1i} + \delta_i, \quad i = 1, 2, 3.
\]

Theorem 9. Suppose that $\lambda_0, \alpha_0, e_0, K_0 > 0$ are selected such that
\[
\alpha_0 K_0 > \left( \frac{\alpha_0 p}{p - 1} + \left( \frac{2p - 1}{p} \right)^2 \lambda_0^2 \right) e_0^2,
\]
and Assumptions 1 and 2 hold. Then, all trajectories of the system (42) converge in finite time to the region
\[
\Omega = \left\{ \|\tilde{z}\| \leq \left( \frac{\gamma_j}{L(t)} \right)^{(p-1)/(p-2)} y_j \right\},
\]
where $\tilde{z} = [L_1^{(p-1)/p} |z_{1i}|^{(p-1)/p} \text{sign}(z_{1i}), L_2^{(p-1)/p} |z_{2i}|^{(p-1)/p} \text{sign}(z_{2i}) + e_0 L_2 z_{1i} - z_{2i}]^T$ and the positive scalars $y_j$ will be defined later.

Proof. Let the Lyapunov function be chosen as
\[
V_2(z) = \frac{\alpha_0 p}{p - 1} L_2^{(p-1)/p} |z_{1i}|^{(p-1)/p} |z_{2i}|^{(p-1)/p} + K_0 L_2 z_{1i}^2 + \frac{1}{2} \tilde{z}_{1i}^2
\]
\[
+ \frac{1}{2} \left( \lambda_0 L_2^{(p-1)/p} |z_{1i}|^{(p-1)/p} \text{sign}(z_{1i}) + e_0 L_2 z_{1i} - z_{2i} \right)^2.
\]
The selected Lyapunov function can be expressed as
\[
V_2(z) = \left( \frac{\alpha_0 p}{p - 1} + \frac{1}{2} \lambda_0^2 \right) L_2^{(p-1)/p} |z_{1i}|^{(p-1)/p} + \frac{1}{2} \tilde{z}_{1i}^2
\]
\[
+ \left( K_0 + \frac{1}{2} e_0^2 \right) L_2 z_{1i}^2 + \lambda_0 e_0 |z_{1i}| L_2^{(p-1)/p} |z_{1i}|^{(p-1)/p}
\]
\[
- \lambda_0 L_2^{(p-1)/p} |z_{1i}|^{(p-1)/p} \text{sign}(z_{1i}) z_{2i} - e_0 L_2 z_{1i} z_{2i},
\]
which can be written as
\[
V_2(z) = \xi^T \Pi_1 \xi,
\]
where
\[
\Pi_1 = \begin{bmatrix} \frac{2\alpha_0 p}{p - 1} + \lambda_0^2 & \lambda_0 e_0 & -\lambda_0 \\ \alpha_0 e_0 & (2K_0 + e_0^2) - e_0 & -e_0 \\ -\lambda_0 & -e_0 & 2 \end{bmatrix}.
\]
It satisfies
\[
\sigma_{\min} (\Pi_1) \|\xi\|^2 \leq V_2 \leq \sigma_{\max} (\Pi_1) \|\xi\|^2,
\]
where \( \| \xi \|^2 = L^2 (p-1)/p |z_{i1}|^{2(p-1)/p} + L^2 z_{i1}^2 + z_{i2}^2 \). The time derivative of \( V_2 \) is obtained as

\[
V_2 \leq \frac{1}{2} \left( 4\alpha_0 + \lambda_0^2 \frac{p-1}{p} \right) L^{(p-2)/p} |z_{i1}|^{(p-2)/p} \text{sign}(z_{i1}) \dot{z}_{i1} + 2z_{i2} \dot{z}_{i2} + \left( 2K_0 + \epsilon_0^2 \right) L^2 z_{i1} \dot{z}_{i1} + \lambda_0 \rho \left( \frac{2p-1}{p} \right) L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) \dot{z}_{i1} + \lambda_0 L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) \dot{z}_{i1} + \epsilon_0 L \dot{z}_{i1} + \epsilon_0 L \dot{z}_{i2} + \epsilon_0 L \dot{z}_{i1} + \epsilon_0 L \dot{z}_{i2}.
\]

Substituting \( \dot{z}_{i1} \) and \( \dot{z}_{i2} \) into (50), we obtain

\[
V_2 \leq \frac{1}{2} \left( 4\alpha_0 + \lambda_0^2 \frac{p-1}{p} \right) L^{(p-2)/p} |z_{i1}|^{(p-2)/p} \text{sign}(z_{i1}) \times \left( z_{i2} - \lambda_0 L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) - \epsilon_0 L \dot{z}_{i1} \right) + 2z_{i2} \left( -\alpha_0 L |z_{i1}|^{(p-2)/p} \text{sign}(z_{i1}) - K_0 L^2 z_{i1} + \delta_1 \right) + \left( 2K_0 + \epsilon_0^2 \right) L^2 z_{i1} \times \left( -\lambda_0 L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) - \epsilon_0 L \dot{z}_{i1} + \dot{z}_{i2} \right) + \left( 2p-1 \right) \lambda_0 \epsilon_0 L \dot{z}_{i1} \times \left( -\lambda_0 L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) - \epsilon_0 L \dot{z}_{i1} + \dot{z}_{i2} \right) + \lambda_0 L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) - \epsilon_0 L \dot{z}_{i1} + \dot{z}_{i2} + \lambda_0 L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) - \epsilon_0 L \dot{z}_{i1} + \dot{z}_{i2}.
\]

After lengthy algebraic manipulation, one obtains

\[
V_2 \leq |z_{i1}|^{-1/p} L^{-1/p} \times \left( \alpha_0 \lambda_0 + \lambda_0^3 \frac{p-1}{p} \right) |z_{i1}|^{2(p-1)/p} L^{2(p-1)/p} - 2\lambda_0 \frac{p-1}{p} L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) z_{i2} + \left( \lambda_0 K_0 + \frac{1}{2} \lambda_0 \epsilon_0^2 \frac{6p-2}{p} \right) z_{i1}^2 L^2 - \lambda_0 \frac{p-1}{p} L^{(p-1)/p} |z_{i1}|^{(p-1)/p} \text{sign}(z_{i1}) z_{i2} + \left( \epsilon_0 K_0 + \epsilon_0^3 \frac{3p-2}{p} \right) z_{i1}^{2(p-1)/p} L^{2(p-1)/p} + \left( \epsilon_0 K_0 + \epsilon_0^3 \right) z_{i1}^2 L^2 + 2\epsilon_0^2 L \dot{z}_{i1} + \dot{z}_{i2}^2.
\]
By Assumption 2 and using \( \| \xi \| \geq \| \Gamma_1 \| \), one obtains

\[
\dot{V}_2 = -\| \xi \|^{-1} L^{-1} L (t) \sigma_{\min}(\Omega_1) \| \xi \|^2
- L (t) \sigma_{\min}(\Omega_2) \| \xi \|^2 + |\delta_\epsilon| \| \Gamma_1 \| \| \xi \|

+ \dot{L}(t) / L \sigma_{\min}(\Pi_2) \| \xi \|^2.
\]

Using (49), the expression (56) becomes

\[
\dot{V}_2 = -L(t) \sigma_{\min}(\Omega_1) \| \xi \|^{(p-2)/(p-1)} V_2^{1/2}
- L (t) \sigma_{\min}(\Omega_2) V_2 + \frac{\| \Gamma_1 \|}{\sigma_{\min}(\Pi_1)} V_2^{1/2}
+ \frac{\dot{L}(t)}{L} \sigma_{\max}(\Pi_2) \| \xi \|^2.
\]

From simplicity, we define

\[
\gamma_1 = \frac{\sigma_{\min}(\Omega_1)}{\sigma_{\max}(\Pi_1)}, \quad \gamma_2 = \frac{\| \sigma_{\min}(\Omega_2) \|}{\sigma_{\max}(\Pi_1)},
\gamma_3 = \frac{\sigma_{\max}(\Omega_2)}{2\sigma_{\min}(\Pi_1)}, \quad \gamma_4 = \frac{\sigma_{\max}(\Pi_2)}{2\sigma_{\min}(\Pi_1)},
\]

where \( \gamma_1, \gamma_2, \gamma_3, \) and \( \gamma_4 \) are positive constants. Thus, (57) can be written as

\[
\dot{V}_2 \leq -L(t) \gamma_1 \| \xi \|^{(p-2)/(p-1)} V_2^{1/2}
- L(t) \gamma_2 - \frac{\dot{L}(t)}{L} \gamma_4 V_2.
\]

Because \( \dot{L}(t) \geq 0 \) such that the term \( L(t) \gamma_2 - (\dot{L}(t)/L) \gamma_4 \) is positive in finite time, it follows from (59) that, if \( L(t) \gamma_1 \| \xi \|^{(p-2)/(p-1)} > \gamma_3 \), the error system (42) will converge in finite time to the region

\[
\Omega = \left\{ \| \xi \| \leq \left( \frac{\gamma_3}{L(t) \gamma_1} \right)^{(p-1)/(p-2)} \right\}.
\]

In fact, we can choose \( \lambda_1, \lambda_2, \lambda_3, \) and \( \lambda_4 \) such that \( \gamma_3 / L(t) \gamma_1 < 1 \). With \( p > 2, (p - 1)/(p - 2) \) being sufficiently large, so \( \xi \) is sufficiently small in finite time.

\( \square \)

**Remark 10.** The control law (38) includes an adaptive law which is used to compensate for the derivative of total disturbances \( \tilde{d} \). Normally, the bound of \( \tilde{d} \) is much smaller than the bound of \( \dot{d} \), so this supports the high accuracy of our proposed method.

### 5. Simulation Results

An example of attitude control of flexible spacecraft is presented with numerical simulations to demonstrate the performance of the developed controllers (25) and (38). The spacecraft is assumed to have the nominal inertia matrix \([33]\)

\[
J = \begin{bmatrix}
350 & 3 & 4 \\
3 & 270 & 10 \\
4 & 10 & 190
\end{bmatrix} \text{kg} \cdot \text{m}^2
\]
and coupling matrices
\[
\delta = \begin{bmatrix}
6.45637 & 1.27814 & 2.15629 \\
-1.25619 & 0.91756 & -1.67264 \\
1.11678 & 2.48901 & -0.83674 \\
1.23637 & -2.6581 & -1.12503
\end{bmatrix} \text{kg}^{1/2} \cdot \text{m/s}^2, \quad (62)
\]
respectively. The first four elastic modes that have been considered in the model used for simulating a spacecraft are \( \omega_{n1} = 0.7681, \omega_{n2} = 1.1038, \omega_{n3} = 1.8733, \) and \( \omega_{n4} = 2.5496 \text{rad/sec} \) with damping \( \xi_1 = 0.0056, \xi_2 = 0.0086, \xi_3 = 0.013, \) and \( \xi_4 = 0.025. \) The initial states of the rotation motion are given by
\[
Q(0) = \begin{bmatrix} 0.3 & -0.1 & 0.2 & 0.9274 \end{bmatrix}^T, \quad (63)
\]
\[
\omega(0) = 0_{3 \times 1} \text{rad/sec}, \quad 0_{4 \times 1}.
\]

For the controller (25), the chosen gains are given as \( \mu_1 = \text{diag}(15, 15, 15), \mu_2 = \text{diag}(10, 10, 10), \mu_3 = \text{diag}(5, 5, 5), \) and \( \mu_4 = \text{diag}(10, 10, 10). \) On the other hand, for controller (38), the control gains are selected to be \( \lambda_0 = 15, \alpha_0 = 10, \epsilon_0 = 10, \) \( K_0 = 15, \) and \( I = 5 \times 10^5. \) For both control algorithms, we use the same sliding manifold (23) with the constant \( \kappa = 1.2. \)

The attitude control problem is considered in the presence of external disturbance \( d(t). \) The external disturbances are described as
\[
d(t) = \begin{bmatrix}
0.3 \cos(0.1t) + 0.1 \\
0.15 \sin(0.1t) + 0.3 \cos(0.1t) \\
0.3 \sin(0.1t) + 0.1
\end{bmatrix} \text{N-m}. \quad (64)
\]
And the desired angular velocity tracking is given by

\[ \omega_d(t) = \begin{bmatrix} -0.04 \cos(0.2t) \\ -0.04 \sin(0.2t) \\ 0.05 \sin(0.2t) + \cos(0.2t) \end{bmatrix} \text{ rad/sec} \quad (65) \]

together with

\[ q_d(0) = [0 \ 0 \ 0]^T. \quad (66) \]

For simulation results with controllers (25) and (38), the attitude quaternion tracking errors are shown in Figures 1 and 7, and angular velocity tracking errors are illustrated in Figures 2 and 8. Controller (38) gives smoother attitude and angular velocity tracking outputs than controller (25). From Figures 3 and 9, it can be seen that the sliding vectors are on the sliding surface \( s = 0 \) after 40 seconds. The control torques of the controllers (38) and (25) are shown in Figures 4 and 10, respectively. It can be seen that controller (38) gives smoother responses of control torques. With the larger magnitude, controller (38) makes the responses go to zero faster than controller (25), so it gives smoother responses during the first 40 seconds and this improves the transient performance. Thus, under the control law (38) the smoother velocity and attitude tracking error responses are obtained. The responses of modal displacements are presented in Figures 5, 6, 11, and 12, in which a low vibration level is illustrated for controller (38) in comparison with controller (25). For controller (25), the boundary layer \( \|s\| \leq 7.63 \times 10^{-5} \) is achieved in finite time. Regarding the accuracy, the bounds on \( \|q_e\| \) and \( \|\omega_e\| \) are \( \|q_e\| \leq 5.12 \times 10^{-5} \) and \( \|\omega_e\| \leq 4.28 \times 10^{-5} \) with the sampling time \( h = 0.005 \). Also, for controller (38), the boundary layer \( \|s\| \leq 4.7 \times 10^{-5} \) is reached in finite time. Regarding the accuracy, the bounds on \( \|q_e\| \) and \( \|\omega_e\| \) are
developed to deal with quaternion-based spacecraft-attitude-tracking maneuvers. For the second control law, an adaptive-gain second-order sliding mode control algorithm is designed to relax the requirement of prior knowledge on the bound of system uncertainties. Both control laws achieve high-precision tracking performance and strong robustness ability. The concepts of the Lyapunov stability are employed to ensure a finite-time property of the proposed controllers. Numerical simulations on attitude tracking control are provided to demonstrate the performance of the developed controllers.

6. Conclusions

The proposed finite-time controllers have been successfully applied to attitude tracking maneuvers of a flexible spacecraft. The first controller based on the novel SOSMC algorithm is developed to deal with quaternion-based spacecraft-attitude-tracking maneuvers. For the second control law, an adaptive-gain second-order sliding mode control algorithm is designed to relax the requirement of prior knowledge on the bound of system uncertainties. Both control laws achieve high-precision tracking performance and strong robustness ability. The concepts of the Lyapunov stability are employed to ensure a finite-time property of the proposed controllers. Numerical simulations on attitude tracking control are provided to demonstrate the performance of the developed controllers.
