The paper presents the energy density improvement using magnetic circuit analysis of the interior permanent magnet motor. The leakage flux from the conventional structure is improved with modified magnetic circuit to improve the energy and thereby the torque value. This is approached with a double stator structure design. The proposed structure is investigated with two design variations, namely, the double stator with thin pole shoe and the double stator with thick pole shoe motors. Variations in the mechanical parameters of the all the developed models are analyzed through the finite element analysis tool. In all investigations the magnetic source is fixed in both the permanent magnet volume and coil magnetomotive force, respectively, as 400 mm³ per each pole and 480 Ampere turns per pole. From the analysis the best fit magnetic structure based on the torque characteristics is derived and is fabricated for the same volume as that of the conventional structure for performance evaluations. It is found out that there is improvement on the motor constant square density for the proposed improved magnetic circuit through the best fit double stator with thick pole shoe by about 83.66% greater than that of the conventional structure.

1. Introduction

Single phase interior permanent magnet (IPM) motors are adopted in many low cost applications such as in fan, blowers, and other domestic appliances [1–5]. The main disadvantage of using single phase compared to three-phase permanent magnet motor is its inability to self-start [6–8]. However, for specific application such as the mechanical chopper, the single phase motor is the most popular application due to the safety consideration. The requirement for such type of motor is of high torque with low cogging torque values. A high torque performance motor usually comes with high cogging characteristic that introduces torque ripple inside the motor. A pure sinusoidal torque characteristic ensures uniform flux distribution that produce smooth speed rotation

with negligible torque ripple [9–12]. The cogging torque is caused by the variation of the magnetic energy of the field due to the interaction of permanent magnet (PM) and the slot under the mechanical angular position of the rotor [13–15]. There are many possible ways to reduce cogging torque such as skewing, optimizing, or varying the magnet pole arc width and introduction of dummy slots [16, 17]. However, each of them gives significant variations in the output torque value. The increase in magnetic energy significantly increases the torque value that is realized by resizing the volume of the magnet or with introduction of larger number of coil turn [18–20]. However, the flux density in some parts of stator or rotor of permanent magnet motor is increased leading to saturation value as the volume of magnet is increased. At this saturation point, the magnetic energy no longer contributes

to torque generation and is considered as air gap that is highly ineffective. Therefore, study on ways to optimize the magnetic energy flow perpendicular to the air gap surface inside a permanent magnet motor is to be investigated at the first stage. An optimal air gap magnetic energy with reduction of cogging torque value is realized through a sinusoidal torque waveform. Then, the process of resizing the PM volume or adding the number of coil turn is used to estimate the performance limit of the desired motor.

This paper presents the analysis on the magnetic circuit design of single stator and double stator and the improvement in the magnetic energy of the double stator with magnetic circuit design. Analysis on the variations of the mechanical parameter that changes the optimal magnetic energy in the air gap that contributes to the generation of torque characteristics of the all structures is presented. Finite element analysis (FEA) is used as a numerical tool to derive the torque characteristics based on various combinations of taper parameters. The analysis result shows that minimum value of total harmonic distortion (THD) is found by optimizing the dimensions of the width of slot and that of the rotor. Also it is found that with reducing height of stator teeth a symmetrical torque waveform is evolved. The analysis is evaluated based on the value of the minimum total harmonic distortion (THD), the maximum fundamental torque T_f , the maximum peak torque T_p , and the minimum cogging torque T_c . For comparative evaluations, the motor constant square density (G) is used. The model of improved series magnetic circuit is fabricated and tested experimentally. The comparison result shows that measurement results have good agreement with the simulation result.

2. Machine Design and Magnetic Circuit Design Analysis

2.1. Single Stator Structure. Figure 1 shows the typical single stator interior permanent magnet (SSIPM) [16–20]. In this research, the 6-pole 6-slot configuration of permanent magnet motor is considered. This is due to the specific application that requires both torque and speed for portable mechanical chopper used in agricultural sector. The overall diameter of the permanent magnet motor is set for 55 mm with 5 mm diameter of shaft. The permanent magnet is made from NdFeB grade of 42 with a dimension of 4 mm of width and 5 mm of height. The technical property of the permanent magnet is shown in Table 1. The shaft is made from nonmagnetic steel (SUS304). The rotor and stator are made up of standard silicon steel known as JI: 50H800. The stack length and the air gap length between stator and rotor are set for 20 mm and 0.1 mm, respectively.

It comprises of a stationary stator and the rotational rotor that moves to develop the torque. With variety in design structure available in the literature, the above structure shows the conventional design with an outside stationary rotor and an inside cylindrical rotor coupled to the output shaft. The stator comprises of set of energised copper coils in succession to generate the magnetic flux. The stator flux interacts with the rotor, which is mounted inside the rotor in such a way

TABLE 1: Parameters varied in this investigation.

Property	Values
Remanent flux density, B_r [T]	1.28–1.32
Coercivity, H_c [kA/m]	>923
Intrinsic coercivity, iH_c [kA/m]	>955
BH max, kJ/m ³	318–342
Operating temperature, T	20°C to 120°C

that it can turn to align itself with the fields generated by the coils. This full alignment force generates torque, turning the rotor so that it moves the load through the shaft.

2.2. Magnetic Circuit Analysis of Single Stator Structure. Figure 2 shows single stator interior permanent magnet (SSIPM) motor type that forms two parallel magnetic circuits: one magnetic circuit is enclosed by stator and coils while the other magnetic circuit is in the rotor side. However, only magnetic circuit in the stator side is involved in the torque generation process as it consists of air gap where by the force is developed in this region. In this magnetic circuit, it has much reluctance as the flux is surpassing from the permanent magnet to the stator and coming back to its origin point. The reluctances in other magnetic circuit which are $2R_{rp1}$, $2R_{rp2}$, and R_{rp3} unused as the magnetic energy of the permanent magnet is been divided (reluctance torque) and not being used for torque production. The net reluctance in the magnetic circuit is given as

$$R = [R_{osy} + 2(R_{sps} + R_{sp}) + 2(R_{rp}) + 2R_{ag}]. \quad (1)$$

The reluctance torque R_r in the rotor circuit that is unused is given as follows:

$$R_r = [2R_{rp1} + 2R_{rp2} + R_{rp3}] \quad (2)$$

is unused as there is no useful energy produced in the circuit. In other words, if the unused leakage flux in the air gap is effectively utilized through another magnetic circuit, then the torque density can be improved.

2.3. Magnetic Circuit Design Concept. The motivation on the introduction of magnetic circuit in the rotor part of the single stator interior permanent magnet (SSIPM) structure is proposed in this section. The design improvements in the magnetic circuit are highly influenced by the property of the material that is involved in the energy conversion process and also the effective area of energy conversion. From the first principles of magnetism, the reluctance in a magnetic circuit is given as

$$R = \frac{l_g}{\mu A_g}, \quad (3)$$

where “ R ” is the reluctance value for the length of the energy conversion contact surface and “ A_g ” is the area of cross section of the contact surface. Ideally the variations in the length of the magnetic flux flow and the variations in the

FIGURE 1: Conventional SSIPM. (a) Structural configurations; (b) fabricated SSIPM motor.

FIGURE 2: Magnetic circuit analysis of the SSIPM. (a) Magnetic flux flow path; (b) equivalent magnetic circuit flow.

contact area between the parts of the magnetic circuit would heavily influence the net magnetic circuit values and thereby the torque density value of the machine. In a magnetic circuit with the air gap $l_g > 0$, most of the MMF is expended on the air gap and most of the energy is stored in the air gap with its volume $A_g l_g$, where A_g is the cross section area of the air gap. The energy per volume is given as

$$w = \frac{W}{A_g l_g} = \frac{1}{2} B_g H = \frac{1}{2} \frac{B_g^2}{\mu_0}, \quad (4)$$

where $B_g = \mu_0 H = \mu_0 (Ni/z)$, $z = l_g$, and i is the instantaneous electric current. Therefore the energy in the reluctance torque produced surface is given as

$$W = \frac{\mu_0 (Ni)^2}{l_g} A_g. \quad (5)$$

The reluctance magnetic circuit from the conventional single stator structure is converted to dual magnetic circuit using the double stator topology wherein the field magnetomotive force (mmf) is established through coil (Ni); the air gap introduces the air-gap section area and length. This evolves in the dual magnetic circuit, namely, outer stator magnetic circuit and the inner stator magnetic circuit. In this way the unused magnetic circuit in the inner rotor is converted in another magnetic circuit that helps to improve the torque generation in the air gap contact surface. This structure with double stator magnetic circuit is referred to as double stator IPM (DSIPM). The approach on introduction of dual magnetic circuit to increase energy density is proposed for switched reluctance motor (SRM) in [21, 22] and also for brushless DC motor (BLDC) in [23].

FIGURE 3: Magnetic circuit analysis of the DSIPM. (a) Magnetic flux flow path; (b) equivalent magnetic circuit flow.

2.4. Double Stator Interior Permanent Magnet (DSIPM) Machine. The rotor leakage flux from the SSIPM is catered with the introduction of another stator structure inside the machine, known as double stator interior permanent magnet (DSIPM) motor. It has two stators known as an outer and inner stator. Theoretically, this two magnetic circuits arrangement provides higher torque production compared to single stator since two air gaps are provided in between stator and rotor. Based on the magnetic equivalent circuit of this model, the flux has to go through $2R_{osp}$, $2R_{osps}$, $2R_{orp}$, and R_{osy} for outer stator side magnetic circuit. In the inner stator side magnetic circuit the flux has to go through $2R_{isp}$, $2R_{isps}$, $2R_{irp}$, and R_{isy} . This contributes higher reluctance which affects the flux through any cross section of a magnetic circuit. The feature that includes the additional stator is introduced in the rotor side known as double stator, with parallel magnetic circuit topology (Figure 3). The resultant magnetic circuit of the DSIPM (only for one sector of energy conversion) of magnetic circuit is as given by

$$R = [R_{osy} + 2(R_{sps} + R_{sp}) + 2(R_{orp}) + 2R_{ag}] \quad (6)$$

$$\parallel [R_{isy} + 2(R_{sps} + R_{sp}) + 2(R_{orp}) + 2R_{ag}].$$

2.5. Magnetic Circuit Improvements. However, there is a large area of ferromagnetic material on the rotor part that affects the flux through any cross section of rotor magnetic circuit. The value of R_{orp} and R_{ag} is critical in developing the torque density as it is the point at which the effective magnetic energy and the electromagnetic energy interacts to develop the torque. By the variations of the mechanical parameter at

this point contact the energy density is improved. The effect of the converging area at the point of contact (between the magnet and the stator) is improved with the use of pole shoe. Further to the conversion of the DSIPM of parallel magnetic circuit to series magnetic circuit by changing the orientation of the magnet. The introduction of the pole shoe divides the flux path in the magnetic circuit introducing reluctance components. The variations of the reluctance components are investigated through the variations in their height and width. Further the size ratio of the magnet influences the torque density due to the orientation of the magnetic grains inside the machine.

This variation in the magnet in this investigation is classified to be of the DSIPM with thin pole shoe and DSIPM with thick pole shoe. The resultant magnetic circuit reluctance value is as shown in

$$R = [R_{osy} + 4(R_{sps} + R_{sp}) + 2(R_{orp}) + 4R_{ag}] \quad (7)$$

$$+ [R_{isy} + 2(R_{irp})].$$

Based on DSIPM, there is a large area of ferromagnetic material on the rotor part. The higher reluctance allows flux leakage to occur at inner air gap which contributes to negative torque production. Therefore, this ferromagnetic material area must be decreased. To address this negative effect the magnetic circuit is enhanced with the introduction of pole shoes in the magnet surfaces. Two different types of magnetic structure are analyzed, namely, DSIPM with thin pole shoe and DSIPM with thick pole shoe. As seen in this structure the optimal magnetic energy in the air gap is affected by the permanent magnet area encapsulated. With varying the

$$f_{ni} = \left(- \int T_{ik} \delta_k w_n \right) d\nabla. \quad (10)$$

FIGURE 6: Mesh setting inside the FEA. (a) Mesh of the design; (b) six layers of mesh in the air gap set for FEA.

FIGURE 7: Magnetic circuit analysis using FEA.

3.4. Analysis Parameters. Table 2 shows the various parameters used in the analysis. As instance for the case of the SSIPM type motor can be seen for each of the ratio the stator to rotor width ($W_s^\circ - W_r^\circ$) the taper height (H_{spt}) is varied. In this design the maximum swept angle for the analysis is 60° and with a clearance of 6° the possible ratio of ($W_s^\circ - W_r^\circ$) is analysed for other parameters as shown in Table 3.

The double stator topology involves two taper parameters, namely, outer stator taper (H_{ospt}) and inner stator taper (L_{ospt}). Hence for the same ratio values of stator to rotor width value the tapers are varied and the values are plotted. Based on the overall analysis data of taper parameter, an evaluation is proposed to select the best possible fit from the various possible combination values. The method is to plot all data in single graph based on the ratio of slot and pole width as

the taper height is varied. Table 3 shows the taper parameters used in the single stator and double stator topology.

4. Results and Discussions

4.1. Numerical Result Analysis. For each of the combinations from Table 3 the values of T_m , T_c , T_f , and THD for the single and double stator topology are investigated and are plotted as in Table 4. From the values plotted result the analysis is done based on the min. THD, max. T_f , max. T_m , and min. T_c values. The analysis motivated in the evaluation of the proper evaluation strategy is used in selecting the best fit of permanent magnet motor. The individual computed values from the Table 4 is plotted and evaluation condition (as shown in the redline) is used to choose the best of the

magnetic circuit structure. Table 5 shows the values of T_m , T_c , T_f , and THD for each evaluation type. With respect to the choice on the minimum THD evaluation type of SSIPM the values of T_m , T_c , T_f , and THD are 0.97 Nm, 0.008 Nm, 0.566 Nm, and 57.88%, respectively. For double

stator topology, the selections of min. THD evaluation type of DSIPM for values of T_m , T_c , T_f , and THD are 1.308 Nm, 0.0120 Nm, 0.648 Nm, and 91.77%, respectively. Meanwhile, for selection of min. THD evaluation types of DS thin pole shoe for values of T_m , T_c , T_f , and THD are 1.0454 Nm,

TABLE 4: Selection of min. THD, max. T_f , max. T_m , and min. T_c based on evaluation type.

TABLE 5: Values of T_m , T_c , T_f , and THD based on evaluation types.

	T_m [Nm]	T_c [Nm]	T_f [Nm]	THD %	T_m [Nm]	T_c [Nm]	T_f [Nm]	THD %	T_m [Nm]	T_c [Nm]	T_f [Nm]	THD %	T_m [Nm]	T_c [Nm]	T_f [Nm]	THD %
Min THD	0.97	0.008	0.566	57.88	1.308	0.0120	0.648	91.77	1.045	0.041	0.852	30.71	2.01	0.2325	1.60	42.56
Max T_f	1.13	0.016	0.699	70.09	1.306	0.0195	0.809	101.12	1.583	0.072	1.169	39.99	2.08	0.2303	1.65	43.37
Max T_m	1.58	0.016	0.671	92.74	2.322	0.0335	0.661	148.14	2.352	0.064	1.1563	67.54	2.94	0.3512	1.58	61.19
Min T_c	0.909	0.002	0.413	86.46	1.397	0.0084	0.711	107.72	1.224	0.004	0.8086	51.06	1.36	0.0731	1.07	48.53

FIGURE 9: Choice on the best fit value of T_m , T_c , T_f , and THD. (a) Maximum torque; (b) minimum cogging torque; (c) fundamental torque; (d) total harmonic distortion.

0.041 Nm, 0.852 Nm, and 30.71%, respectively. Selections of min. THD evaluation type of DS thick pole shoe for values of T_m , T_c , T_f , and THD are 2.0172 Nm, 0.11769 Nm, 1.6045 Nm, and 42.56%, respectively. For value of T_m , the DS thick pole shoe produced the highest T_m of 3.0 Nm with higher cogging torque 0.38 Nm, respectively. The average of T_f in DSIPM is approximately 0.7 Nm and increases up to an average of 1.0 Nm in DS thin pole shoe while 1.5 Nm in DSIPM with thick pole shoe. This shows that DSIPM with thick pole shoe produces better result of torque component. It can be seen that the range of THD value is from 91% compared to that of the DSIPM, whereas for DS thin pole shoe it is from 30% to 90%. For DSIPM with thick pole shoe, the range of THD value is from 40% to 90%. The optimal value is selected (as shown by red line) to indicate the improvement of each model. The fabricated SSIPM is with the best fit that exhibits performance with the choice of minimum THD.

Figure 9 shows the optimum value of T_m , T_c , T_f , and THD as indicated by red lines of Table 5. It can be seen that the optimal of max. T_m is increased for each proposed magnetic circuit topology. Figure 9(a) shows that the maximum torque is achieved with the magnetic circuit improvements, with reduced cogging torque as seen in Figure 9(b). But for the DSIPM and DSIPM with thin pole shoe the cogging torque

is reduced but the harmonic content is increased that would eventually reduce the average torque. The DSIPM with thick pole shoe exhibits reduced harmonic content deriving higher average torque along with the maximum torque. Each of the proposed magnetic circuit developed produces significant increment in terms of T_m , T_c , T_f , and decrement of THD but the choice on the torque density makes the DS thick pole shoe a better choice due to its better fundamental torque with reduced THD.

4.2. Experimental Evaluations. The fabricated best fit DSIPM with thick pole shoe for the same size and volume as that of the fabricated SSIPM is as shown in Figure 10.

The equipment arrangement for static torque measurement setup is shown in Figure 11. The fabricated motor is attached to a jig. An encoder is attached to the body of gear in order to detect the rotor position when the gear is rotated. The encoder is attached to Lab View in computer that received a signal from Data Acquisition Card. The purpose of gear is to extend the rotation time of the pulley so that smaller degree rotation can be achieved. As the pulley is rotated manually, the gear rotates in the common shaft of torque sensor and of the developed motor. The developed motor is being applied
