The variational iteration method (VIM) is applied to solve singular perturbation initial value problems with delays (SPIVPDs). Some convergence results of VIM for solving SPIVPDs are given. The obtained sequence of iterates is based on the use of general Lagrange multipliers; the multipliers in the functionals can be identified by the variational theory. Moreover, the numerical examples show the efficiency of the method.

1. Introduction

Singular perturbation initial value problems with delays play an important role in the research of various applied sciences, such as control theory, population dynamics, medical science, environment science, biology, and economics [1, 2]. These problems are characterized by a small parameter \( \varepsilon \) multiplying the highest derivatives, and the state variables depend not only on the value of the time, but also on the value prior to the time. Because the classical Lipschitz constant and one-sided Lipschitz constant are generally of size \( O(\varepsilon^{-1}) \) (\( 0 < \varepsilon \ll 1 \)), the classical convergence theory, B-convergence theory, and D-convergence theory cannot be directly applied to SPIVPDs.

Starting from pioneering ideas going back to Inokuti-Sekine-Mura method [3], the variational iteration method was first proposed in later 1990s by He [4–6]. By recent years, this method has been extensively applied to various ODEs, integral equations, delay differential equations and fractional differential equations, two-point boundary value problems, oscillations, and stiff ODEs, notably, He [7, 8], Wazwaz [9, 10], Draganescu et al. [11, 12], Saadatmandi and Dehghan [13], Salkuyeh [14], Lu [15], Xu [16], Rafei et al. [17], Darvishi et al. [18], Tatari and Dehghan [19], Mamode [20], Saadati and Dehghan [21], Yu [22], Marinca et al. [23], Yang and Dumitru [24], and Wu [25] to mention only a few. Recently, Zhao and Xiao [26] have applied this method for solving singular perturbation initial value problems. For more comprehensive survey on this method and its applications, the reader is referred to the review articles [26–28] and the references therein.

In this paper, we apply the VIM to SPIVPDs to obtain the analytical or approximate analytical solutions. The convergence results of VIM for solving SPIVPDs are obtained. Some illustrative examples confirm the theoretical results.

2. Convergence Analysis

2.1. Case 1.

Consider the following singular perturbation initial value problem with delays:

\[
\begin{aligned}
x'(t) &= f(t, x(t), x(t-\tau), y(t), y(t-\tau)), \\
0 &\leq t \leq T,
\end{aligned}
\]
\[ \epsilon y'(t) = g(t, x(t), x(t - \tau), y(t), x(t - \tau)), \]
\[ 0 < \epsilon \ll 1, \]
\[ x(t) = \varphi(t), \quad y(t) = \psi(t), \quad t \leq 0, \]
(1)

where \( x \in \mathbb{R}^n \) and \( y \in \mathbb{R}^m \) are the state variables and \( \epsilon \) is the singular perturbation parameter. \( f : [-\tau, T] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}^n, g : [-\tau, T] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}^n \) are given continuous mappings which satisfy the following Lipschitz conditions:

\[ \| f(t, x_1, u_1, y_1, v_1) - f(t, x_2, u_2, y_2, v_2) \| \leq l_1(t) \| x_1 - x_2 \| + l_2(t) \| u_1 - u_2 \| + l_3(t) \| y_1 - y_2 \| + l_4(t) \| v_1 - v_2 \|, \]
(2a)

\[ \| g(t, x_1, u_1, y_1, v_1) - g(t, x_2, u_2, y_2, v_2) \| \leq k_1(t) \| x_1 - x_2 \| + k_2(t) \| u_1 - u_2 \| + k_3(t) \| y_1 - y_2 \| + k_4(t) \| v_1 - v_2 \|, \]
(2b)

where \( l_i(t), k_i(t) (i = 1, \ldots, 4) \) are continuous bounded functions.

According to VIM, we can construct the correction functional as follows:

\[ x_{m+1}(t) = x_n(t) + \int_0^t \lambda_1(s,t) \left( x_n'(s) - \tilde{f}(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) \right) ds, \]
(3a)

\[ y_{m+1}(t) = y_n(t) + \int_0^t \lambda_2(s,t) \left( y_n'(s) - \frac{1}{\epsilon} \tilde{g}(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) \right) ds, \]
(3b)

where \( \lambda_1(s,t), \lambda_2(s,t) \) are general Lagrange multipliers, which can be defined optimally via variational theory, and \( \tilde{f}, \tilde{g} \) denote the restrictive variation; that is, \( \delta \tilde{f} = \delta \tilde{g} = 0. \) Thus, we have

\[ \delta x_{m+1}(t) = \delta x_n(t) + \int_0^t \lambda_1(s,t) \delta x_n'(s) ds, \]
(4a)

\[ \delta y_{m+1}(t) = \delta y_n(t) + \int_0^t \lambda_2(s,t) \delta y_n'(s) ds, \]
(4b)

and the stationary conditions are obtained as

\[ 1 + \lambda_1(s,t)|_{t=0} = 0, \quad \frac{\partial \lambda_1(s,t)}{\partial s} = 0, \]
\[ 1 + \lambda_2(s,t)|_{t=0} = 0, \quad \frac{\partial \lambda_2(s,t)}{\partial s} = 0. \]
(5)

Moreover, the general Lagrange multiplier can be readily identified by

\[ \lambda_1(s,t) = \lambda_2(s,t) = -1. \]
(6)

Therefore, the variational iteration formulas can be written as

\[ x_{m+1}(t) = x_n(t) - \int_0^t \left( x_n'(s) - f(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) \right) ds, \]
(7a)

\[ y_{m+1}(t) = y_n(t) - \int_0^t \left( y_n'(s) - \frac{1}{\epsilon} g(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) \right) ds. \]
(7b)

Now, we show that the iterative sequences \( \{x_n(t)\}_{n=1}^{\infty}, \{y_n(t)\}_{n=1}^{\infty} \) defined by (7a) and (7b) with \( x_0(t) = \varphi(t), y_0(t) = \psi(t) \) converge to the solution of (1).

**Theorem 1.** Let \( x(t), x_i(t) \in (C^1[0, T])^n, y(t), y_i(t) \in (C^1[0, T])^m, i = 0, 1, \ldots \) The sequences defined by (7a) and (7b) with \( x_0(t) = \varphi(t), y_0(t) = \psi(t) \) converge to the solution of (1).

**Proof.** Obviously from system (1), we have

\[ x(t) = x(t) \]
\[ - \int_0^t \left( x'(s) - f(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) ds, \]
(8a)

\[ y(t) = y(t) \]
\[ - \int_0^t \left( y'(s) - \frac{1}{\epsilon} g(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) ds. \]
(8b)

Introduce \( E_i x(t) = x_i(t) - x(t), E_i y(t) = y_i(t) - y(t), E_i x(t - \tau) = x_i(t - \tau) - x(t - \tau), E_i y(t - \tau) = y_i(t - \tau) - y(t - \tau), i = 0, 1, \ldots \) where \( E_i x(0) = E_i y(0) = 0, j = 0, 1, \ldots \) Now from (7a), (7b)-(8a), and (8b) we obtain

\[ E_{n+1} x(t) = E_n x(t) \]
\[ - \int_0^t \left( E_n x'(s) - (f(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)), y_n(s), y_n(s - \tau)) \right) ds, \]
(8a)
$$E_{n+1}y(t) = E_n y(t) - \int_0^t \left( E_n y'(s) - \frac{1}{\varepsilon} \right) \times (g(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) - g(s, x(s), x(s - \tau), y(s), y(s - \tau))) \, ds. \tag{9}$$

Moreover, we can derive

$$E_{n+1}x(t) = \int_0^t \left( f(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) - f(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) ds, \tag{10a}$$

$$E_{n+1}y(t) = \frac{1}{\varepsilon} \int_0^t \left( g(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) - g(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) ds. \tag{10b}$$

Now, the integration interval is split into two parts

$$E_{n+1}x(t) = \int_0^t \left( f(s, x_n(s), \varphi(s - \tau), y_n(s), \psi(s - \tau)) - f(s, x(s), \varphi(s - \tau), y(s), \psi(s - \tau)) \right) ds$$

$$+ \int_t^T \left( f(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) - f(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) ds, \tag{11}$$

$$E_{n+1}y(t) = \frac{1}{\varepsilon} \int_0^t \left( g(s, x_n(s), \varphi(s - \tau), y_n(s), \psi(s - \tau)) - g(s, x(s), \varphi(s - \tau), y(s), \psi(s - \tau)) \right) ds$$

$$+ \int_t^T \left( g(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) - g(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) ds.$$

From the Lipschitz conditions (2a) and (2b), we have

$$\left( \begin{array}{c} \lVert E_{n+1}x(t) \rVert \\ \lVert E_{n+1}y(t) \rVert \end{array} \right) \leq \left( \begin{array}{ccc} l_1 & l_2 & l_3 \\ k_1 & k_2 & k_3 \\ \frac{1}{\varepsilon} & \frac{1}{\varepsilon} & \frac{1}{\varepsilon} \end{array} \right) \left( \int_0^t \left( \lVert E_n x(s) \rVert + \lVert E_n y(s) \rVert \right) ds \right)$$

$$+ \left( \frac{l_2}{k_2} \frac{l_4}{k_4} \frac{l_3}{k_3} \frac{l_1}{k_1} \right) \left( \int_0^T \left( \max_{-\tau \leq s \leq T} \lVert E_0 x(s) \rVert \right) ds \right), \tag{12}$$

where $l_i = \max_{0 \leq s \leq T} l_i(s)$, $k_i = \max_{0 \leq s \leq T} k_i(s)$, $i = 1, \ldots, 4$. Therefore,

$$\left( \begin{array}{c} \lVert E_1 x(t) \rVert \\ \lVert E_1 y(t) \rVert \end{array} \right) \leq \left( \begin{array}{ccc} l_1 & l_2 & l_3 \\ k_1 & k_2 & k_3 \\ \frac{1}{\varepsilon} & \frac{1}{\varepsilon} & \frac{1}{\varepsilon} \end{array} \right) \left( \int_0^t \left( \lVert E_0 x(s) \rVert + \lVert E_0 y(s) \rVert \right) ds \right)$$

$$+ \left( \frac{l_2}{k_2} \frac{l_4}{k_4} \frac{l_3}{k_3} \frac{l_1}{k_1} \right) \left( \int_0^T \left( \max_{-\tau \leq s \leq T} \lVert E_0 x(s) \rVert \right) ds \right), \tag{13}$$

Moreover, we can derive

$$\left( \begin{array}{c} \lVert E_n x(t) \rVert \\ \lVert E_n y(t) \rVert \end{array} \right) \leq \frac{T^n}{n!} \left( \begin{array}{ccc} l_1 & l_2 & l_3 \\ k_1 & k_2 & k_3 \\ \frac{1}{\varepsilon} & \frac{1}{\varepsilon} & \frac{1}{\varepsilon} \end{array} \right) \left( \max_{-\tau \leq s \leq T} \lVert E_0 x(s) \rVert \right)$$

$$\times \left( \frac{\Theta(\varepsilon)}{\Theta(1)} \frac{\Theta(\varepsilon)}{\Theta(1)} \right) \left( \max_{-\tau \leq s \leq T} \lVert E_0 y(s) \rVert \right), \tag{14}$$

Noting that $\varepsilon, T, \max_{-\tau \leq s \leq T} \lVert E_0 x(s) \rVert, \max_{-\tau \leq s \leq T} \lVert E_0 y(s) \rVert, l_i, k_i, i = 1, \ldots, 4$ are constants. By using Stirling's formula, we have

$$\left( \begin{array}{c} \lVert E_n x(t) \rVert \\ \lVert E_n y(t) \rVert \end{array} \right) \leq \frac{(T^2\varepsilon/n)^n}{\sqrt{2\pi n} \left( 1 + \Theta(1/n) \right)}$$

$$\times \left( \frac{\Theta(\varepsilon)}{\Theta(1)} \frac{\Theta(\varepsilon)}{\Theta(1)} \right) \left( \max_{-\tau \leq s \leq T} \lVert E_0 x(s) \rVert \right) \left( \max_{-\tau \leq s \leq T} \lVert E_0 y(s) \rVert \right), \tag{15}$$

thus, \( (\lVert E_n x(t) \rVert, \lVert E_n y(t) \rVert)^T \to 0 \) as $n \to \infty$. \hfill \Box
2.2. Case 2. Consider the special case of (1):

\[ x'(t) = Ax(t) + F(t, x(t), x(t - \tau), y(t), y(t - \tau)), \]
\[ 0 \leq t \leq T, \]

\[ \epsilon y'(t) = By(t) + G(t, x(t), x(t - \tau), y(t), y(t - \tau)), \]
\[ 0 < \epsilon \ll 1, \]

\[ x(t) = \phi(t), \quad y(t) = \psi(t), \quad t \leq 0, \]

(16)

where \( F : [-\tau, T] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^r \times \mathbb{R}^r \rightarrow \mathbb{R}^n \), \( G : [-\tau, T] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^r \times \mathbb{R}^r \rightarrow \mathbb{R}^r \) are given continuous mappings which satisfy the Lipschitz conditions (2a) and (2b); the matrices \( A = (a_{ij}) \in \mathbb{R}^{n \times n} \), \( B = (b_{ij}) \in \mathbb{R}^{r \times n} \) can be decomposed into \( A = A_0 + A_1 \), \( B = B_0 + B_1 \), respectively, where \( A_0 = \text{diag}(a_{11}, a_{22}, \ldots, a_{nn}) \) and \( B_0 = \text{diag}(b_{11}, b_{22}, \ldots, b_{nn}) \):

\[
\|F(t, x_1, u_1, v_1) - F(t, x_2, u_2, v_2)\| \leq p_1(t) \|x_1 - x_2\| + p_2(t) \|u_1 - u_2\|,
\]

(17a)

\[
\|G(t, x_1, u_1, v_1, y_1) - G(t, x_2, u_2, v_2, y_2)\| \leq q_1(t) \|x_1 - x_2\| + q_2(t) \|u_1 - u_2\|,
\]

(17b)

\[
\|\dot{x}_n(t) - \dot{x}_n(t) - A_0 x_n(t) - A_1 \bar{x}_n(t)\|
\]

\[
- F(s, x_n(s), x_n(s - \tau),
\]

\[
y_n(s), y_n(s - \tau))\] ds,

(21)

Moreover, the general Lagrange multipliers can be readily identified by

\[
A_1(s, t) = -\exp(-A_0(s - t)),
\]

\[
A_2(s, t) = -\exp\left(-\frac{B_0}{\epsilon}(s - t)\right).
\]

Therefore, the variational iteration formula can be written as

\[
x_{n+1}(t) = x_n(t)
\]

\[
+ \int_0^t A_1(s, t) \left(x_n'\left(s\right) - A_0 x_n\left(s\right) - A_1 \bar{x}_n\left(s\right) - F\left(s, x_n\left(s\right), x_n\left(s - \tau\right),
\]

\[
y_n\left(s\right), y_n\left(s - \tau\right)\right)\] ds,

(22a)

\[
y_{n+1}(t)
\]

\[
= y_n(t) - \int_0^t e^{-\frac{B_0}{\epsilon}(s - t)} \times \left(y_n'(s) - \frac{1}{\epsilon}
\]

\[
\times \left(B_0 y_n(s) + B_1 \bar{y}_n(s)
\]

\[
+ G(s, x_n(s), x_n(s - \tau), y_n(s),
\]

\[
y_n(s - \tau))\] ds.

(22b)

The following theorem shows that the sequences \( \{x_n(t)\}_{n=1}^{\infty}, \{y_n(t)\}_{n=1}^{\infty} \) defined by (22a) and (22b) with \( x_0(t) = \phi(t), y_0(t) = \psi(t) \) converge to the solution of (16).
Theorem 2. Let $x(t), x_i(t) \in (C^1[0, T])^{n_1}, y(t), y_i(t) \in (C^1[0, T])^{n_2}, i = 0, 1, \ldots$. The sequences defined by (22a) and (22b) with $x_0(t) = \phi(t), y_0(t) = \psi(t)$ converge to the solutions of (16).

Proof. By a similar process to the proof of Theorem 1, we can easily obtain. Obviously from system (16) we have

\[
x(t) = x(t) - \int_0^t (x'(s) - Ax(t) - F(s, x(s), x(s - \tau), y(s), y(s - \tau))) \, ds,
\]

\[
y(t) = y(t) - \int_0^t \left( y'(s) - \frac{1}{\varepsilon} (By(t) + G(s, x(s), x(s - \tau), y(s), y(s - \tau))) \right) \, ds.
\]

Introduce $E_i x(t) = x_i(t) - x(t), E_i y(t) = y_i(t) - y(t), i = 0, 1, \ldots$, where $E_i x(0) = E_i y(0) = 0, j = 0, 1, \ldots$. Now from (22a), (22b)-(23a), and (23b) we obtain

\[
E_{n+1} x(t) = \int_0^t e^{-A_s(s-t)} \left( A_i E_n x(s) + \left( F(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) - F(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) \right) \, ds,
\]

\[
E_{n+1} y(t) = \int_0^t e^{-B_s(s-t)} \left( \frac{1}{\varepsilon} (B_i E_n y(s) + \left( G(s, x_n(s), x_n(s - \tau), y_n(s), y_n(s - \tau)) - G(s, x(s), x(s - \tau), y(s), y(s - \tau)) \right) \right) \, ds.
\]

Similarly, we can derive

\[
\left( \frac{\|E_{n+1} x(t)\|}{\|E_{n+1} y(t)\|} \right) \leq e(\varepsilon) \left( \frac{T^n}{n!} \left( A_i + p_1 + p_2 \frac{q_1 + q_2}{\varepsilon} B_i + q_3 + q_4 \right)^n \right) \times \left( \frac{\max_{T \leq s \leq t} \|E_0 x(s)\|}{\max_{T \leq s \leq t} \|E_0 y(s)\|} \right) \leq e(\varepsilon) \left( \frac{(Te/\varepsilon)/n}{\sqrt{2\pi n} \left( 1 + O(1/n) \right)} \right) \times \left( \frac{\max_{T \leq s \leq t} \|E_0 x(s)\|}{\max_{T \leq s \leq t} \|E_0 y(s)\|} \right),
\]

where $e(\varepsilon) = \max_{0 \leq s \leq T} \{ e^{-A_s(s-t)}, e^{-B_s(s-t)} \}, p_i = \max_{0 \leq s \leq T} p_i(s), q_i = \max_{0 \leq s \leq T} q_i(s), i = 1, \ldots, 4$. Noting that $\varepsilon, T, \|A_i\|, \|B_i\|, e(\varepsilon), p_i, q_i, i = 1, \ldots, 4, \max_{T \leq s \leq t} \|E_0 x(s)\|$ and $\max_{T \leq s \leq t} \|E_0 y(s)\|$ are constants, we can derive from (26) that $(\|E_n x(t)\|, \|E_n y(t)\|)^T \to 0$ as $n \to \infty$.

3. Numerical Examples

In this section, some numerical examples are given to show the efficiency of the VIM for solving SPIVPs.

Example 3. Consider SPIVPD (cf. [2]):

\[
x'(t) = x(t-1) y(t-1) - 1000x(t) + 2y^2(t) + R_x(t), \quad t > 0,
\]
\[
\begin{align*}
\epsilon y'(t) &= x(t-1) - y(t-1) - (1 + x(t)) y(t) + R_y(t), \\
x(t) &= e^{-0.5t} + e^{-0.2t}, \quad y(t) = -e^{-0.5t} + e^{-0.2t}, \\
& \quad 0 < \epsilon \ll 1,
\end{align*}
\]

(27)

where
\[
\begin{align*}
R_x(t) &= 999.5e^{-0.5t} + 999.8e^{-0.2t} + e^{-t-1} \\
& \quad - e^{-0.4(t-1)} - 2e^{-t} - 2e^{-0.4t} + 4e^{-0.7t}, \\
R_y(t) &= (0.5\epsilon - 1)e^{-0.5t} + (1 - 0.2\epsilon)e^{-0.2t} \\
& \quad - e^{-0.5(t-1)} - e^{-t} - e^{-0.4t}.
\end{align*}
\]

(28)

By using the VIM in Case 1, we construct the following iteration formula:
\[
\begin{align*}
x_{n+1}(t) &= x_n(t) \\
& \quad - \int_0^t \left( x'_n(s) - x_n(s-1) y_n(s-1) \
+ 1000x_n(s) - 2y_n(s) - R_x(s) \right) ds,
\end{align*}
\]

(29a)

\[
\begin{align*}
y_{n+1}(t) &= y_n(t) \\
& \quad - \int_0^t \left( y'_n(s) - \frac{1}{\epsilon} \times \left( x_n(s-1) - y_n(s-1) - (1 + x_n(s)) \right) \times y_n(s) + R_y(s) \right) ds.
\end{align*}
\]

(29b)

To get iterate sequence, we start with an initial approximation \( x_0(t) = e^{-0.5t} + e^{-0.2t}, \ y_0(t) = -e^{-0.5t} + e^{-0.2t} \) and let \( \epsilon = 10^{-6} \). By means of formulas (29a) and (29b), we have
\[
\begin{align*}
x_1(t) &= e^{-0.5t} + e^{-0.2t}, \\
y_1(t) &= -e^{-0.5t} + e^{-0.2t}.
\end{align*}
\]

(30)

Figure 1 shows the efficiency of VIM for SPIVPDs.

Example 4. Consider SPIVPD (cf. [2]):
\[
\begin{align*}
x'(t) &= 2x(t-1) + y(t-1) - 1000x(t) + y(t) + R_x(t), \\
x(t) &= 1 + 10e^{-(t+1)/2} + 5e^{-(t+1)/\epsilon}, \quad t \leq 0, \\
y(t) &= -1 - 9e^{-(t+1)/2} + 4e^{-(t+1)/\epsilon}, \quad t \leq 0,
\end{align*}
\]

(31)

where
\[
\begin{align*}
R_x(t) &= 10004e^{-(t+1)/2} + \left( \frac{4996 - 5}{\epsilon} \right) e^{-(t+1)/\epsilon} \\
& \quad - 11e^{-t/2} - 14e^{-t/\epsilon} + 1000,
\end{align*}
\]

(32)

By using the VIM in Case 2, we construct the following iteration formula:
\[
\begin{align*}
x_{n+1}(t) &= x_n(t) \\
& \quad - \int_0^t e^{1000(s-t)} \left( x'_n(s) - 2x_n(s-1) - y_n(s-1) \
+ 1000x_n(s) - y_n(s) - R_x(s) \right) ds,
\end{align*}
\]

(33)
To get iterate sequence, we start with an initial approximation \( x_0(t) = 1 + 10e^{-(t+1)/2} + 5e^{-(t+1)/\varepsilon} \), \( y_0(t) = -1 - 9e^{-(t+1)/2} + 4e^{-(t+1)/\varepsilon} \) and let \( \varepsilon = 10^{-3} \). By means of formulas (33) and (34), we have
\[
\begin{align*}
x_1(t) &= 1 + 10e^{-(t+1)/2} + 5e^{-(t+1)/\varepsilon}, \\
y_1(t) &= -1 - 9e^{-(t+1)/2} + 4e^{-(t+1)/\varepsilon}.
\end{align*}
\]

Figure 2 shows the efficiency of VIM for SPIVPDs.

4. Conclusion

The VIM used in this paper is the variational iteration algorithm I; there are also variational iteration algorithms II and III [29]. In this paper, we apply the VIM to obtain the analytical or approximate analytical solutions of SPIVPDs. The convergence results of VIM for solving SPIVPDs are given. The illustrative examples show the efficiency of the method. When considering the system (16), the choice of correction functionals of Case 1 or Case 2 relies on the practical problems and this choice will result in the difference of the speed of convergence.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
