This paper presents the decentralized trackers using the observer-based suboptimal method for the interconnected time-delay singular/nonlinear subsystems with closed-loop decoupling property. The observer-based suboptimal method is used to guarantee the high-performance trajectory tracker for two different subsystems. Then, due to the high gain that resulted from the decentralized tracker, the closed-loop system will have the decoupling property. An illustrative example is given to demonstrate the effectiveness of the proposed control structure.

1. Introduction

The singular system model is a natural presentation of dynamic systems, such as power systems [1] and large-scale systems [2, 3]. In general, an interconnection of state variable subsystems is conveniently described as a singular system, even though an overall state space representation may not even exist. Over the past decades, much attention has been focused on the decentralized control [4–6] for time-delay singular systems. In [7], the problem of decentralized stabilization has been discussed for nonlinear singular large-scale time-delay control systems with impulsive solutions. The \( H_{\infty} \) control for singular systems with state delay has been presented in [8]. And the decentralized output feedback control problem [9] is considered for a class of large-scale systems with unknown time-varying delays.

In the recent years, a large number of control systems are characterized by interconnected large-scale subsystems, and many practical examples have been applied to decentralized control systems. The decentralized control of interconnected large-scale systems has commonly appeared in our modern technologies, such as transportation systems, power systems, and communication systems [10–12]. However, a survey of the literature indicates that the singular system issue has seldom been studied in such systems. Many research [13–16] results concerning the singular/nonlinear system have successfully solved lots of complex problems. For the above reasons, we will discuss the decentralized control of the interconnected large-scale time-delay singular subsystem and nonlinear subsystem.

In this paper, we consider the time-delay effect. In practical applications, the time-delay effect [17–19] may result in an unexpected and unsatisfactory system performance, even including the serious instability, if it is ignored in the design of control systems. In order to overcome this problem, the controller design method [20, 21] is necessary to be further explored in this paper. Sequentially, the decentralized tracker with the high-gain property will make the closed-loop system own the decoupling property.

This paper is organized as follows. Section 2 describes the problem of interest. Section 3 presents the observer-based suboptimal digital tracker. Section 4 presents the simulation results of interconnected time-delay singular/nonlinear subsystems. Finally, Section 5 draws conclusions.
2. System and Problem Description

Consider the time-delay system consisting of two interconnected MIMO subsystems shown as

\[ \text{S1: } \dot{x}_1(t) = Ax_1(t) + A_1x_1(t - \tau_{i1}) + B_1u_1(t - \tau_{i3}) + h_{12}x_2(t - \tau_{c2} - \tau_{c1}) \]
\[ + g_2(x_2(t - \tau_{c2}))u_2(t - \tau_{c2}) \]  
\[ y_1(t) = C_1x_1(t - \tau_{o1}) \] 

\[ \text{S2: } \dot{x}_2(t) = f_2(x_2(t - \tau_{c2})) + g_2(x_2(t - \tau_{c2})) \]
\[ + h_{21}x_1(t - \tau_{c1} - \tau_{c2}) \]
\[ y_2(t) = C_2x_2(t - \tau_{o2}) \]

where \( x_1(t) \) and \( x_2(t) \) are the state vectors, \( u_1(t) \) and \( u_2(t) \) are the control input vectors, and \( y_1(t) \) and \( y_2(t) \) are the output vectors. \( f_2(\cdot) \) and \( g_2(\cdot) \) are nonlinear functions of the states \( x_2(t) \) of S2. \( E, A, A_1, B_1, C_1, \) and \( C_2 \) are known as constant system matrices of appropriate dimensions and \( E \) is a singular matrix. State time delays \( \tau_{i1} \) and \( \tau_{i2} \), interconnection time delays \( \tau_{c1} \) and \( \tau_{c2} \), input time delays \( \tau_{i3} \) and \( \tau_{o1} \), and output time delays \( \tau_{o2} \) are assumed to be known. The time delays of interconnected state vectors \( h_{12}x_2(t - \tau_{c2} - \tau_{c1}) \) and \( h_{21}x_1(t - \tau_{c1} - \tau_{c2}) \) are induced from multiple sensors at different rates to accurately produce a reliable navigation solution.

The subsystem S1 is the time-delay singular system and subsystem S2 is the time-delay nonlinear subsystem. Before designing the controller, the decentralized modeling of the interconnected time-delay system is proposed in Figure 1. The notation \( L(\cdot) \) through this paper is a time lag operator; for example, \( L(\tau_{ij})u(t) = u(t - \tau_{ij}) \).

It is very difficult to directly design the tracker and observer for S1 and S2 because their system models are not nonsingular and linear models. To solve this problem, the previously proposed method in [21] and the OKID (observer/Kalman filter identification) method in [22] are appropriately utilized to make S1 and S2 become the equivalent linear time-delay nonsingular subsystems. As a result, the process becomes quite simple. Besides, as long as the designed tracker for each subsystem has the high-gain property, the designed global system will have the closed-loop decoupling property.

We will use the proposed schematic design in Figure 1 to construct the methodology of the decentralized control for the interconnected time-delay singular/nonlinear subsystems with the closed-loop decoupling property.

3. Main Results

In this section, we construct the methodology of the decentralized control by using the design concept of the
observer-based suboptimal digital tracker to control time-
delay singular subsystem and time-delay nonlinear subsys-
tem, respectively. Before designing the controller, we need
to obtain the equivalent time-delay linear nonsingular sub-
system and the equivalent time-delay linear subsystem. The
problem of decentralized stabilization is discussed in the
appendix.

3.1. The Equivalent Time-Delay Linear Nonsingular Subsystems for
the Time-Delay Singular/Nonlinear Subsystems. From the
schematic design methodology of Figure 1, and by using the
previous method in [20], we can make the time-delay singular
subsystems (1a) and (1b) become the equivalent time-delay
regular system as follows:

\[
\begin{align*}
\dot{x}_s (t) &= A_s x_s (t) + \bar{A}_d x_s (t - \tau_{a1}) + B_d v_c (t - \tau_{i1}) \\
&\quad + h_1^s x_1 (t - \tau_{c2} - \tau_{a1}), \\
y_1 (t) &= C_1 x_1 (t - \tau_{a1}) - D_1 v_c (t - \tau_{i1}),
\end{align*}
\]

(3a) and (3b), respectively. Before designing the controller, we need
to obtain the equivalent time-delay linear nonsingular sub-
system and the equivalent time-delay linear subsystem. The
problem of decentralized stabilization is discussed in the
appendix.

Remark A.0. Notably, definitions of the regular pencil [23]
and the standard pencil [24] are satisfied on no state delay
term in systems (1a) and (1b). If \( A_1 \) exists, then definitions of
the regular pencil and the standard pencil do not guarantee
that systems (1a) and (1b) can be decomposed into the
equivalent time-delay regular system.

Similarly, the time-delay nonlinear subsystems (2a) and
(2b) can transform the equivalent time-delay linear sub-
system by OKID method [21, 22] as follows:

\[
\begin{align*}
x_{d2} \left(k T_2 + T_2\right) &= G_{d2} x_{d2} \left(k T_2\right) + H_{d2} u_d \left(k T_2 - \tau_{c2}\right), \\
y_{d2} \left(k T_2\right) &= C_{d2} x_{d2} \left(k T_2 - \tau_{a2}\right),
\end{align*}
\]

(4a)

where \( G_{d2}, H_{d2}, \) and \( C_{d2} \) are the identified parameters by
OKID method. The corresponding continuous-time system of
(4a) and (4b) is described by

\[
\begin{align*}
x_{c2} (t) &= A_{c2} x_{c2} (t) + B_{c2} u (t - \tau_{c2}), \\
y_{c2} (t) &= C_{c2} x_{c2} (t - \tau_{c2}).
\end{align*}
\]

(5a) and (5b)

Notably, \( A_{c2}, B_{c2}, \) and \( C_{c2} \) are known as constant system
matrices of appropriate dimensions.

The equivalent subsystems (3a), (3b), and (5a) and (5b)
will be applied to the observer-based suboptimal digital
tracker [21] for the singular/nonlinear subsystem in the next
subsection and finally we proposed the schematic design
methodology of decentralized control for the interconnected
time-delay singular/nonlinear subsystems with closed-loop
decoupling property.

3.2. The Observer-Based Suboptimal Digital Tracker Design [21].
Consider the continuous time-delay singular subsystems (3a)
and (3b) or the time-delay subsystems (5a) and (5b).

Here, we take the time-delay singular subsystems (3a)
and (3b) to design the observer-based suboptimal digital
tracker and the design results are similar to the time-delay
subsystems (5a) and (5b).

Consider the continuous time-delay singular subsystems
(3a) and (3b) without the time delay of interconnected state
vector \( h_1^s x_1 (t - \tau_{c2} - \tau_{a1}) \). By [21], \( T_1 \) is the sampling period.
Let the state delay time be given by \( \tau_{a1} = \eta_1 T_1 + \sigma_1 \), where \( 0 \leq \sigma_1 < T_1 \) and \( \eta_1 \geq 0 \) is an integer, and let the input delay
time be given by \( \tau_{i1} = \eta_1 T_1 + \sigma_1 \), where \( 0 \leq \sigma_1 < T_1 \) and \( \eta_1 \geq 0 \) is an integer. The time-delay singular subsystems (3a)
and (3b), by both the Newton extrapolation method and the
Chebyshev quadrature method [25, 26], become

\[
\begin{align*}
\ddot{x}_{ds} \left((k + 1) T_1\right) &= G \ddot{x}_{ds} (k T_1) + \tilde{G}_1 (1) \ddot{x}_{ds} (k T_1 - \rho_1 T_1 + T_1) \\
&\quad + \tilde{G}_1 (2) \ddot{x}_{ds} (k T_1 - \rho_1 T_1) + \tilde{G}_1 (3) \ddot{x}_{ds} (k T_1 - \rho_1 T_1 - T_1) \\
&\quad + H_1 (0) v_d (k T_1 - \eta_1 T_1) + H_1 (1) v_d (k T_1 - \eta_1 T_1 - T_1),
\end{align*}
\]

(6)

where

\[
\begin{align*}
G &= \exp^{A, T}, \\
\tilde{G}_1 (1) &= \frac{T_1}{2} \left[ Q_1 (2) + Q_1 (3) \right] \tilde{A}_d, \\
\tilde{G}_1 (2) &= T_1 \left[ Q_1 (2) - Q_1 (3) \right] \tilde{A}_d, \\
\tilde{G}_1 (3) &= \frac{T_1}{2} \left[ Q_1 (3) - Q_1 (2) \right] \tilde{A}_d, \\
H_1 (0) &= \left[ G^{1 - \gamma} - I_n \right] A_s^{-1} B_d, \\
H_1 (1) &= \left[ G^{1 - \gamma} \right] A_s^{-1} B_d
\end{align*}
\]

(7)
in which

\[
\begin{align*}
y_1 &= \frac{\sigma_1}{T_1}, \\
\beta_1 &= \frac{\Gamma_1}{T_1}, \\
Q_1 (1) &= [G - I_n] (A_s T_1)^{-1}, \\
Q_1 (2) &= \left[ Q_1 (1) - (1 - \beta_1) I_n - \beta_1 G \right] (A_s T_1)^{-1}, \\
Q_1 (3) &= \left[ 2 Q_1 (2) - (1 - \beta_1)^2 I_n - \beta_1^2 G \right] (A_s T_1)^{-1}.
\end{align*}
\]

(8)

Some terms in (6) may be combined because of the same
delay, so (6) can be reduced to

\[
\begin{align*}
\ddot{x}_{ds} \left((k + 1) T_1\right) &= G \ddot{x}_{ds} (k T_1) + \sum_{j=1}^{M} \tilde{G}_j \ddot{x}_{ds} (k T_1 - iT_1) \\
&\quad + H v_d \left(k T_1 + \sum_{j=1}^{M} \tilde{H}_j v_d (k T_1 - jT_1)\right).
\end{align*}
\]

(9)
The time-delay state $\bar{x}_1(t - \tau_{o1})$ for $kT_1 \leq t - \tau_{o1} < (k+1)T_1$ must be evaluated as follows:

$$\bar{x}_1(t - \tau_{o1}) = e^{A_1(t - \tau_{o1} - kT_1)} \bar{x}_{ds}(kT_1) + \int_{kT_1}^{t - \tau_{o1}} e^{A_1(t - \tau_{o1} - \lambda)} A_1 \bar{x}_{ds}(\lambda - \tau_{o1}) d\lambda + \int_{kT_1}^{t - \tau_{o1}} e^{A_1(t - \tau_{o1} - \lambda)} B_1 \psi_d(\lambda - \tau_{o1}) d\lambda$$

$$= \delta_1(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1) + \left[ \delta_1^{(1)}(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1 - \rho_1 T_1 + T_1) + \delta_1^{(2)}(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1 - \rho_1 T_1) + \delta_1^{(3)}(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1 - \rho_1 T_1 - T_1) \right] + \left[ \phi_1^{(0)}(t - \tau_{o1} - kT_1) \psi_d(kT_1 - \eta_1 T_1) + \phi_1^{(1)}(t - \tau_{o1} - kT_1) \psi_d(kT_1 - \eta_1 T_1 - T_1) \right]$$

where

$$\delta_1(t - \tau_{o1} - kT_1) = e^{A_1(t - \tau_{o1} - kT_1)}$$

$$\delta_1^{(1)}(t - \tau_{o1} - kT_1) = T_1 \frac{1}{2} \left[ q_1^{(2)} + q_1^{(3)} \right] A_1$$

$$\delta_1^{(2)}(t - \tau_{o1} - kT_1) = T_1 \frac{1}{2} \left[ q_1^{(3)} - q_1^{(2)} \right] A_1$$

$$\delta_1^{(3)}(t - \tau_{o1} - kT_1) = T_1 \frac{1}{2} \left[ q_1^{(3)} - q_1^{(2)} \right] A_1$$

$$\phi_1^{(0)}(t - \tau_{o1} - kT_1) = \begin{cases} O_{n \times m}, & t - \tau_{o1} < \sigma_1 \\ \left[ e^{-A_1 \tau_{o1}} - I_n \right] A_1^* B_1, & t - \tau_{o1} \geq \sigma_1 \end{cases}$$

$$\phi_1^{(1)}(t - \tau_{o1} - kT_1) = \begin{cases} \left[ \delta_1(t - \tau_{o1} - kT_1) - I_n \right] A_1^* B_1, & t - \tau_{o1} < \sigma_1 \\ \delta_1(t - \tau_{o1} - kT_1) \left[ I_n - e^{-A_1 \tau_{o1}} \right] A_1^* B_1, & t - \tau_{o1} \geq \sigma_1 \end{cases}$$

in which

$$q_1^{(1)} = \left[ \delta_1(t - \tau_{o1} - kT_1) - I_n \right] (A_2 T_1)^{-1}$$

$$q_1^{(2)} = \left[ \frac{q_1^{(1)}}{T_1} - \left( \frac{t - \tau_{o1} - kT_1}{T_1} - \beta_1 \right) I_n - \beta_1 \delta_1(t - \tau_{o1} - kT_1) \right] (A_2 T_1)^{-1}$$

Some terms in (10) may be combined as in (9), and (10) can be rewritten as

$$\bar{x}_1(t - \tau_{o1}) = \bar{x}_{0}(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1) + \sum_{i=1}^{M_1} \bar{x}_0(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1 - iT_1) + \bar{\psi}_0(t - \tau_{o1} - kT_1) \psi_d(kT_1) + \sum_{j=1}^{M_2} \bar{\psi}_j(t - \tau_{o1} - kT_1) \psi_d(kT_1 - jT_1)$$

Then, the output (3b) can be rewritten as

$$y_1(t) = C_{11} \bar{x}_1(t - \tau_{o1}) - D_1 \psi_d(t - \tau_{o1})$$

$$= C_{11} \bar{x}_0(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1) + \sum_{i=1}^{M_1} C_{11} \bar{x}_0(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1 - iT_1) + C_{11} \bar{\psi}_0(t - \tau_{o1} - kT_1) \psi_d(kT_1) + \sum_{j=1}^{M_2} C_{11} \bar{\psi}_j(t - \tau_{o1} - kT_1) \psi_d(kT_1 - jT_1) - \left[ D_1^{(0)} \psi_d(kT_1 - \eta_1 T_1) + D_1^{(1)} \psi_d(kT_1 - \eta_1 T_1 - T_1) \right]$$

where

$$D_1^{(0)} = D_1^{*} (B_1^* B_1)^{-1} H_1^{(0)}$$

$$D_1^{(1)} = D_1^{*} (B_1^* B_1)^{-1} H_1^{(1)}$$

and

$$D_1^{*} = \left[ D_1^{(1)} \right]^T$$

Similarly, some terms in (14) can be combined so (14) can be rewritten as

$$y_1(t) = \bar{C}_{11} \bar{x}_0(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1) + \sum_{i=1}^{M_1} \bar{C}_{11} \bar{x}_0(t - \tau_{o1} - kT_1) \bar{x}_{ds}(kT_1 - iT_1) + \bar{C}_{11} \bar{\psi}_0(t - \tau_{o1} - kT_1) \psi_d(kT_1) + \sum_{j=1}^{M_2} \bar{C}_{11} \bar{\psi}_j(t - \tau_{o1} - kT_1) \psi_d(kT_1 - jT_1)$$

where

$$\bar{\psi}_0, \bar{\psi}_1, \bar{x}_0, \text{and} \bar{\psi}_j$$ are the summation of multiple input-delay terms.

In the following work, we use (13) and (15) to derive the equivalent extended delay-free system as follows:

$$X_d((k+1)T_1) = \bar{C}_o X_d(kT_1) + \bar{H}_2 \psi_d(kT_1)$$

$$y_d(kT_1) = \bar{C}_o X_d(kT_1)$$
where
\[
X_d(kT_1) = [\tilde{x}_d(kT_1), \tilde{x}_d(kT_1 - T_1), \ldots, \tilde{x}_d(kT_1 - M_1T_1), v_d(kT_1 - T_1), \ldots, v_d(kT_1 - M_2T_1), r^*(kT_1) ]^T
\] (17)

means the extended virtual state vector.

By the previous method [21], we derive the observer-based suboptimal tracker for the time-delay singular system with unavailable states using the equivalent extended delay-free system. The extended observer-based suboptimal digital tracker can be represented as
\[
\begin{align*}
\tilde{X}_d(k + 1)T_1 &= \tilde{G}_o\tilde{X}_d(kT_1) + \tilde{H}_oV_d(kT_1) + L_d[y_d(kT_1) - \tilde{C}_e\tilde{X}_d(kT_1)], \\
y_d(kT_1) &= -\tilde{K}(kT_1)\tilde{X}_d(kT_1),
\end{align*}
\] (18a)

(18b)

where \(\tilde{X}_d(kT_1)\) is the estimate of the extended state \(X_d(kT_1)\) in (17) and
\[
\begin{align*}
\tilde{G}_o &= \tilde{G}_e - L_d\tilde{C}_e\tilde{C}_e, \\
\tilde{H}_o &= \tilde{H}_e - L_d\tilde{C}_e\tilde{H}_e, \\
\tilde{K}(kT_1) &= [K_d(kT_1) F_d(kT_1) E_d(kT_1)]
\end{align*}
\] (19)

in which
\[
\begin{align*}
K_d(kT_1) &= \left[ K_{d(0)}(kT_1) K_{d(1)}(kT_1) \ldots K_{d(M_1)}(kT_1) \right], \\
F_d(kT_1) &= \left[ F_{d(1)}(kT_1) \ldots F_{d(M_2)}(kT_1) \right].
\end{align*}
\] (20)

The details of the parameters can be referred to in [21]. Here, the observer-based suboptimal tracker has been completely obtained. Figure 2 presents the realization of decentralized control for the interconnected time-delay singular/nonlinear subsystems.

From Figures 1 and 2, the design procedure can be summarized as the following steps.

**Step 1.** Perform the previously proposed method [21] and the OKID method [22] to determine the equivalent time-delay linear subsystems in Figure 1.

**Step 2.** Design the observer-based suboptimal digital trackers from the equivalent time-delay linear subsystems obtained in Step 1.

**Step 3.** Perform the observer-based suboptimal digital trackers obtained in Step 2. The decentralized control for the interconnected time-delay singular/nonlinear subsystems is shown in Figure 2.

### 4. An Illustrative Example

Consider the time-delay system consisting of two interconnected MIMO subsystems shown as

\[
\begin{align*}
S1: \quad &E\dot{x}(t) = Ax_1(t) + A_1x_1(t - \tau_{s1}) + B_1u_1(t - \tau_{i1}) \\
&\quad + h_{12}^1x_2(t - \tau_{c2} - \tau_{i1}), \\
&y_1(t) = C_1x_1(t - \tau_{o1}), \\
S2: \quad &\dot{x}_2(t) = f_2(x_2(t - \tau_{s2}) + g_2(x_2(t - \tau_{c2})) \\
&\quad \cdot [u_2(t - \tau_{c2}) + h_{21}^1x_1(t - \tau_{c1} - \tau_{i2})], \\
&y_2(t) = C_2x_2(t - \tau_{o2}),
\end{align*}
\] (21a)

(21b)

(22a)

(22b)

where

\[
\begin{align*}
u_1(t) &= \begin{bmatrix} u_{1,1}(t) \\ u_{1,2}(t) \end{bmatrix}, \\
u_2(t) &= \begin{bmatrix} u_{2,1}(t) \\ u_{2,2}(t) \end{bmatrix}, \\
x_1(t) &= \begin{bmatrix} x_{1,1}(t) \\ x_{1,2}(t) \\ x_{1,3}(t) \\ x_{1,4}(t) \\ x_{1,5}(t) \\ x_{1,6}(t) \end{bmatrix}, \\
x_2(t) &= \begin{bmatrix} x_{2,1}(t) \\ x_{2,2}(t) \\ x_{2,3}(t) \\ x_{2,4}(t) \end{bmatrix}.
\end{align*}
\] (23)

The first subsystem S1 of the large-scale system is given as follows:

\[
E = \begin{bmatrix}
1 & 2 & 1 & 1 & -3 & -2 \\
0 & 2 & 2 & 1 & -3 & -3 \\
1 & 2 & 1 & 1 & -3 & -2 \\
1 & 2 & 1 & 3 & -5 & -4 \\
0 & 2 & 1 & 1 & -2 & -2 \\
1 & 0 & 0 & 0 & -1 & 0
\end{bmatrix}, \quad A = I_6,
\]
Figure 2: The decentralized control for the interconnected time-delay singular/nonlinear subsystems.
and \( q = [q_1, q_2]^T \), \( q_1, q_2 \) are the angular positions, \( M(q) \) is the moment of inertia, \( C(q, \dot{q}) \) includes Coriolis and centripetal forces, \( G(q) \) is the gravitational force, and \( \Gamma \) is the applied torque vector. Here, we use the short-hand notations \( \dot{q}_i = \sin(q_i) \) and \( q_i = \cos(q_i) \). The nominal parameters of the system are given as follows: the link masses \( m_1 = 5 \text{ kg}, m_2 = 2.5 \text{ kg} \), the length \( l_1 = l_2 = 0.5 \text{ m} \), and the gravitational acceleration \( g_r = 9.81 \text{ m/s}^2 \). Rewrite (25) in the following form:

\[
\ddot{q} = M^{-1}(q) \left( \Gamma - C(q, \dot{q}) \dot{q} - G(q) \right). \tag{27}\]

Let \( x_1 \) and \( f_1(x_1) \) represent the state of the system and the nonlinear function of the state \( x_1 \), respectively. And the notation is shown as follows:

\[
x_2(t) \equiv [x_{2,1} \ x_{2,2} \ x_{2,3} \ x_{2,4}]^T \equiv [q_1 \ q_2 \ q_2^2 \ q_2^3]^T, \tag{28}\n\]

where \( f_{2,1} = x_{2,1}, f_{2,2} = x_{2,2}, f_{2,3} = x_{2,3}, \) and \( f_{2,4} = \Gamma - C(x_{2,2}, x_{2,4}) - G \). Also, let \( u_2 \equiv \Gamma \), in which \( \Gamma = [\Gamma_1 \ \Gamma_2]^T \).

Calculate the inverse of the matrix \( M \), and then we can have \( M^{-1} = \left[ P_{11} \ P_{12} \right] \left[ P_{21} \ P_{22} \right] \) such that

\[
g_2(x_2(t)) = \begin{bmatrix} 0 & 0 \\ P_{11} & P_{12} \\ 0 & 0 \end{bmatrix}. \tag{29}\n\]

Therefore, the dynamic equation of the two-link robot system can be reformulated as follows:

\[
\ddot{x}_2(t) = f_2(x_2(t - \tau_{c2})) + g_2(x_2(t - \tau_{c2}))u_2(t - \tau_{c2}), \tag{30a}\n\]

\[
y_2(t) = C_2x_2(t - \tau_{c2}), \tag{30b}\n\]

where \( C_2 = \left[ \begin{array}{c} 1 \\ 0 \\ 0 \\ 0 \end{array} \right] \), the sampling period \( T_2 = 0.02 \text{ sec} \), and the initial condition \( x_2(0) = [0 \ 0 \ 0 \ 0]^T \).

Combining the above systems with the nonlinear interconnected terms, the large-scale system can then be shown in Figures 1 and 2, where the nonlinear interconnected terms \( h_{12}(x_{d2}(t)) \) and \( h_{21}(x_{d1}(t)) \) are given as \( \begin{bmatrix} x_{d2,1} \cos(x_{d2,3}) \\ \sin(x_{d2,3}) \end{bmatrix} \) and \( \begin{bmatrix} x_{d1,1} \\ x_{d1,3} \sin(x_{d1,3}) \end{bmatrix} \), respectively. The time delays of the nonlinear interconnected terms are \( \tau_{c1} = 3 \times T_2 \) and \( \tau_{c2} = 1 \times T_1 \), where \( T_1 = 0.01 \text{ sec} \) and \( T_2 = 0.02 \text{ sec} \).

Based on Section 3.1 [20], the time-delay singular subsystem \( S1 \) can be transformed into the equivalent time-delay regular system as follows:

\[
S1: \ 
\dot{x}_1(t) = A_1x_1(t) + A_{d1}x_1(t - \tau_{11}) + B_1v_e(t - \tau_{11}), \tag{31a}\n\]

\[
y_1(t) = C_1x_1(t - \tau_{c1}) - D_1v_e(t - \tau_{c1}), \tag{31b}\n\]
where
\[
A_s = \begin{bmatrix}
1 & 0 & 0 & -0.5001 \\
0 & 0.4999 & -0.25 & -0.4999 \\
0 & 0 & 0.4999 & 0 \\
0 & 0 & 0 & 0.4999
\end{bmatrix},
\]
\[
\tilde{A}_d = \begin{bmatrix}
0.4472 & 0 & 0 & -0.2236 \\
0 & 0.2236 & -0.1118 & -0.2236 \\
0 & 0 & 0.2236 & 0 \\
0 & 0 & 0 & 0.2236
\end{bmatrix},
\]
\[
B_d = \begin{bmatrix}
0.4999 & 0.5001 \\
-0.25 & -0.25 \\
0.4999 & 0.4999 \\
0.4999 & -0.4999
\end{bmatrix},
\]
\[
C_{11} = \begin{bmatrix}
1 & 0 & 1 & 0 \\
1 & 0 & 0 & 0
\end{bmatrix},
\quad
D_1 = \begin{bmatrix}
0 & 2 \\
0.5 & 1.5
\end{bmatrix}.
\]
(32)

By OKID [21, 22] in Figure 1, the identified subsystem S2 is given as
\[
S_2: \quad x_{d2} (k_2 T_2 + T_2) = G_{d2} x_{d2} (k_2 T_2) + H_{d2} u_{d2} (k_2 T_2 - \tau_{i2}),
\]
\[
y_{d2} (k_2 T_2) = C_{d2} x_{d2} (k_2 T_2 - \tau_{o2}),
\]
(33a)

where
\[
G_{d2} = \begin{bmatrix}
1.16 \times 10^0 & -5.39 \times 10^{-2} & -8.39 \times 10^{-2} & 1.15 \times 10^{-2} & 1.48 \times 10^{-8} \\
5.81 \times 10^{-2} & 1.07 \times 10^0 & -9.69 \times 10^{-3} & -8.64 \times 10^{-2} & -3.85 \times 10^{-8} \\
1.83 \times 10^{-1} & 2.44 \times 10^{-3} & 9.23 \times 10^{-1} & -5.00 \times 10^{-2} & -9.23 \times 10^{-9} \\
6.99 \times 10^{-3} & 1.90 \times 10^{-1} & 5.30 \times 10^{-2} & 7.99 \times 10^{-1} & -5.21 \times 10^{-8} \\
-8.04 \times 10^{-2} & 3.30 \times 10^{-3} & 1.38 \times 10^{-8} & -1.29 \times 10^{-8} & -7.21 \times 10^{-3}
\end{bmatrix},
\]
(34)
\[
H_{d2} = \begin{bmatrix}
-4.08 \times 10^{-6} & 2.11 \times 10^{-4} \\
-1.46 \times 10^{-4} & 2.92 \times 10^{-4} \\
2.32 \times 10^{-5} & -2.69 \times 10^{-4} \\
1.98 \times 10^{-4} & -3.77 \times 10^{-4} \\
-6.01 \times 10^{-12} & 1.85 \times 10^{-8}
\end{bmatrix},
\]
\[
C_{d2} = \begin{bmatrix}
6.43 \times 10^{-1} & -8.50 \times 10^{-1} & 5.29 \times 10^{-1} & -6.39 \times 10^{-1} & -1.52 \times 10^{-8} \\
8.72 \times 10^{-1} & 7.84 \times 10^{-1} & 7.35 \times 10^{-1} & 4.80 \times 10^{-1} & -2.02 \times 10^{-8}
\end{bmatrix}.
\]
(35)
in which the input time-delay \(\tau_{i2} = 0.5 \times T_2\) and output time-delay \(\tau_{o2} = 0.5 \times T_2\).

Following the proposed method in this paper, let the reference inputs \(r(t) = \begin{bmatrix} 0.5 \sin(t) & 0.5 \cos(t) \end{bmatrix}^T\) and apply them to subsystem S1 and subsystem S2, respectively. We obtain the observer gain matrix \(L_d\) for S1 and S2 as follows:

S1: 
\[
L_{d1} = \begin{bmatrix}
-7.19 \times 10^{-3} & -1.26 \times 10^2 & 1.00 \times 10^0 \\
1.02 \times 10^0 & 2.60 \times 10^2 & -1.00 \times 10^0 \\
1.98 \times 10^0 & -1.57 \times 10^{-2} & -1.26 \times 10^2 \\
-3.97 \times 10^0 & 2.83 \times 10^{-1} & 2.58 \times 10^2 \\
2.49 \times 10^{-1} & 1.97 \times 10^0 & -1.23 \times 10^0 \\
-2.49 \times 10^{-1} & -3.94 \times 10^0 & 1.18 \times 10^0
\end{bmatrix},
\]

S2: 
\[
L_{d2} = \begin{bmatrix}
-3.90 \times 10^{-1} & -3.39 \times 10^{-1} & -4.23 \times 10^{-1} \\
-3.28 \times 10^{-1} & 3.97 \times 10^{-1} & -3.61 \times 10^{-1} \\
-1.94 \times 10^{-3} & 1.94 \times 10^{-3} & 0 & 0 & 1.09 \times 10^{-4} & 1.15 \times 10^{-4} & 0 \end{bmatrix}^T.
\]
Finally, the scheme of Figure 2 is implemented. For simplification, the numerical analysis is not presented and Figures 4 and 5 show the results of the simulation.

In order to confirm the independence of the control for the two subsystems, the time-varying optimal digital
controller of the subsystem $S_2$ is reduced by multiplying a scalar 0.97 during 4 sec to 6 sec in this simulation. Although the time-varying optimal digital controller of the subsystem $S_2$ is reduced, the tracking performance of the subsystem $S_1$ will not be affected by this condition and the results are shown in Figures 6 and 7.

To show the effectiveness of the proposed method, we compare it with the observer/Kalman filter identification (OKID) method in the simulation for the subsystem $S_2$. Following [20, 21], let the subsystem $S_2$ be excited by the control force $u(t)$ with white noise $u(t) = \begin{bmatrix} u_1(t) & u_2(t) \end{bmatrix}^T$ having zero mean and covariance $\text{diag}\left[\text{cov}(u_1(t)) \quad \text{cov}(u_2(t))\right] = \text{diag}(0.2 \quad 0.2)$. Then, the comparisons between the actual outputs and the OKID method for subsystem $S_2$ are shown in Figure 8, and the comparisons between the actual outputs and the proposed method for subsystem $S_2$ are shown in Figure 9.
Figure 8: (a) The comparison between the system output $y_{d21}(k_2T_2)$ and its observer-based output $y_{okid21}(k_2T_2)$ by OKID for the subsystem $S_2$. (b) The comparison between the system output $y_{d22}(k_2T_2)$ and its observer-based output $y_{okid22}(k_2T_2)$ by OKID for the subsystem $S_2$.

Figure 9: (a) The comparison between the system output $y_{d21}(k_2T_2)$ and its observer-based output $y_{okid21}(k_2T_2)$ by the proposed method for the subsystem $S_2$. (b) The comparison between the system output $y_{d22}(k_2T_2)$ and its observer-based output $y_{okid22}(k_2T_2)$ by the proposed method for the subsystem $S_2$. 
From the comparison between Figures 8 and 9, the effectiveness of the proposed method is better than OKID method in the tracking error performance.

5. Conclusion

This paper presents a systematic methodology of the decentralized control for the interconnected time-delay singular/nonlinear subsystems with closed-loop decoupling property. We use the observer-based suboptimal digital tracker with high gain property to keep the good tracking performance. Moreover, the decoupling property performs very well such that even if some unanticipated fault occurs in some of subsystems, it still will not affect the tracking performance of each subsystem. The proposed methods depend on the decentralized modeling of the interconnected sampled-data time-delay subsystems in Section 2 and the controller design is suitable to time-delay singular/nonlinear subsystems in Section 3. Thus, the proposed method can deal with the signal quantization and sensor delay but cannot deal with intermittent measurements and missing/fading measurements. In future works, we will pay more attention to fault-tolerant control, intermittent measurements, and missing/fading measurements by using the proposed methods.

Appendix

The Decentralized Control Stabilization

The necessary and sufficient conditions for the decentralized stabilization are presented in [29]. Here, we provide the proof for the decentralized stabilization and more details can be seen [29]. The following proofs are cited from [29].

Consider the given system $\Sigma$:

$$\Sigma: \quad x(kT + T) = Ax(kT) + \sum_{i=1}^{v} B_i u_i(kT),$$

$$y_i(kT) = C_i x(kT), \quad i = 1, \ldots, v.$$  (A.1)

The decentralized stabilization problem for $\Sigma$ is to find controllers $\Sigma_i$, $i = 1, \ldots, v$, such that the poles of the closed loop system are in the desired locations in the open unit disc. In order to provide an easier bookkeeping, we define the following matrices:

$$B = [B_1 \cdots B_v], \quad C = [C_1^T \cdots C_v^T]^T,$$

$$K = \text{diag}[K_1 \cdots K_v], \quad L = \text{diag}[L_1 \cdots L_v],$$

$$M = \text{diag}[M_1 \cdots M_v], \quad N = \text{diag}[N_1 \cdots N_v].$$  (A.2)

**Definition A.1.** Consider system $\Sigma$; $\lambda \in C$ is called a decentralized fixed mode if for all block diagonal matrices $H$ one has $\text{det}(\lambda I - A - BHC) = 0$.

**Lemma A.2.** Necessary and sufficient condition for the existence of a decentralized feedback control law for the system $\Sigma$ such that the closed loop system is asymptotically stable is that all the fixed modes of the system are asymptotically stable (in the unit disc).

**Proof.** We first establish necessity. Assume local controllers $\Sigma_i$ together stabilize $\Sigma$ then for any $|\lambda| \geq 1$ there exists a $\delta$ such that $(\lambda + \delta)I - K$ is invertible and the closed loop system replacing $K$ with $K - \delta I$ is still asymptotically stable. This choice is possible because if $\lambda I - K$ is invertible obviously we can choose $\delta = 0$. If $\lambda I - K$ is not invertible, by small enough choice of $\delta$ we can make sure that $(\lambda + \delta)I - K$ is invertible and the closed loop system replacing $K$ with $K - \delta I$ is still asymptotically stable. But the closed loop system when $K - \delta I$ is in the loop is asymptotically stable. In particular, it cannot have a pole in $\lambda$. So

$$\text{det}(\lambda I - A - B [M (\lambda I - (K - \delta I))^{-1} L + N] C) \neq 0.$$  (A.3)

Hence the block diagonal matrix $S = M(\lambda I - (K - \delta I))^{-1}L + N$ has the property that

$$\text{det}(\lambda I - A - BSC) \neq 0.$$  (A.4)

Thus $\lambda$ is not a fixed mode. Since this argument is true for any $\lambda$ on or outside the unit disc, this implies that all the fixed modes must be inside the unit disc. This proves the necessity of the Lemma A.2.

Next, we establish sufficiency. To prove that we can actually stabilize the system, we use a recursive argument. Assume the system has an unstable eigenvalue in $\mu$. Since $\mu$ is not a fixed mode there exists $N_i$ such that

$$A + \sum_{i=1}^{v} B_i N_i C_i$$  (A.5)

no longer has an eigenvalue in $\mu$. Let $k$ be the smallest integer such that an unstable eigenvalue of $A$ is no longer an eigenvalue of

$$A + \sum_{i=1}^{k} B_i N_i C_i,$$  (A.6)

while $N_i$ can be chosen small enough not to introduce additional unstable eigenvalues. Then for the system

$$\left( A + \sum_{i=1}^{k-1} B_i N_i C_i, B_k, C_k \right),$$  (A.7)

an unstable eigenvalue is both observable and controllable. But this implies that there exists a dynamic controller which moves this eigenvalue in the open unit disc without introducing new unstable eigenvalues. Through a recursion, we can move all eigenvalues one-by-one in the open unit disc and in this way find a decentralized controller which stabilizes the system. This proves the sufficiency of Lemma A.2. \qed
