A new class of impulsive differential equations with noninstantaneous fixed time impulses is considered. Uniform stability and uniform asymptotic stability of solutions of the system have been established by employing piecewise Lyapunov functions. An example is also given to illustrate the theoretical results.

1. Introduction

Differential equations are one of the most frequently used tools for mathematical modeling in engineering and life sciences. Many evolution processes are subjected to short term perturbations caused by external interventions during their evolution. Very often, the duration of these effects is negligible acting instantaneously in the form of impulses. Many modeled phenomena which have a sudden change in states such as population dynamics, biotechnology process, chemistry, engineering, and medicine can be formulated by the following impulsive differential equations:

$$\begin{aligned}x' &= f(t, x), \quad t \neq t_k, \\ \Delta x &= I_i(x), \quad t = t_k,\end{aligned}\tag{1}$$

where $i \in N$, $t \in R_+$, $I_i(x) = x(t_i^+) - x(t_i)$, $x \in R^n$, $f: R^+ \times R^n \rightarrow R^n$, $I_i: R^n \rightarrow R^n$, and $0 = t_0 < t_1 < t_2 < t_3 < \dots < \infty$.

Let $t_0 \in R_+$, $x_0 \in R^n$, such that $x(t, t_0, x_0)$ is the solution of system (1), satisfying the initial conditions $x(t_0 + 0, t_0, x_0) = x_0$. Here, the impulsive conditions are the combination of the traditional initial value problem and the short term perturbations whose duration can be negligible in comparison with the duration of such process [1–9].

However, the above short term perturbations could not show the dynamic change of evolution process completely

in pharmacotherapy. We know that the introduction of new drugs in the bloodstream and the consequent absorption for the body are gradual and continuous processes. Thus, we have to use a model to describe such an evolution process. In fact, the above situation has fallen in a new impulsive action, which starts at an arbitrary fixed point and keeps active on a finite time interval. To achieve this aim, a new class of semilinear impulsive differential equations with noninstantaneous impulses is introduced by Hernandez and O'Regan [10] in 2013. Then, the results for the existence of solutions of such equations are established by Pierri et al. [11].

Motivated by [10–13], we introduce a new Lyapunov stability concept for the following semilinear differential equation with noninstantaneous impulses:

$$\begin{aligned}x'(t) &= f(t, x(t)), \quad t \in (s_i, t_{i+1}], \quad i = 0, 1, 2, 3, \dots, m, \\ x(t) &= g_i(t, x(t)), \quad t \in (t_i, s_i], \quad i = 1, 2, 3, \dots, m,\end{aligned}\tag{2}$$

where $0 = t_0 = s_0 < t_1 \leq s_1 \leq t_2 \leq \dots \leq s_{m-1} \leq t_m \leq s_m \leq t_{m+1} = T$ are prefixed numbers, $f: [0, T] \times R \rightarrow R$ is continuous, and $g_i: [t_i, s_i] \times R \rightarrow R$ is continuous for all $i = 1, 2, 3, \dots, m$.

Practically, in system (2), we consider a new model to describe an evolution process, in which an impulsive action starts at an arbitrary fixed point and keeps active on a finite

time interval. Assume that we can measure the state of the process at any time to get a function $x(\cdot)$ as a solution of (2).

The novelty of our paper is to consider a new type of impulsive differential equation (2) with noninstantaneous impulses, finding reasonable conditions to establish Lyapunov's uniform stability and asymptotic uniform stability of solutions [14] of system (2).

In Section 2, we present some preliminaries. In Section 3, uniform stability and asymptotic uniform stability of solutions have been established by using piecewise Lyapunov function. The theoretical results have been illustrated by an example in Section 4.

2. Preliminaries

Let R denote the set of real numbers, $J = [0, T]$, and let $C(J, R)$ be the Banach space of all continuous functions from J into R with the norm $\|x(t)\|_C = \sup\{|x(t)| : t \in J\}$ for $x \in C(J, R)$. We introduce the Banach space $PC(J, R) = \{x \in J \rightarrow R : x \in C((t_k, t_{k+1}], R), k = 0, 1, 2, \dots, m\}$ and $\exists x(t_k^-)$ and $x(t_k^+)$ with $x(t_k^-) = x(t_k)$, $\|x(t)\|_{PC} = \sup\{|x(t)| : t \in J\}$. Meanwhile, we set $PC^1(J, R) = \{x \in PC(J, R) : x' \in PC(J, R)\}$ with $\|x\|_{PC^1} = \max\{\|x\|_{PC}, \|x'\|_{PC}\}$. Clearly, $PC^1(J, R)$ endowed with the norm $\|\cdot\|_{PC^1}$ is also a Banach space.

By virtue of the concept of solutions in [10] and also used in [12], we introduce the following definition.

Definition 1. A function $x \in PC^1(J, R)$ is called a classical solution of the problem

$$\begin{aligned} x'(t) &= f(t, x(t)), \quad t \in (s_i, t_{i+1}], \quad i = 0, 1, 2, 3, \dots, m, \\ x(t) &= g_i(t, x(t)), \quad t \in (t_i, s_i], \quad i = 1, 2, 3, \dots, m, \\ x(0) &= x_0, \quad x_0 \in R, \end{aligned} \quad (3)$$

if x satisfies

$$\begin{aligned} x(0) &= x_0, \\ x(t) &= \begin{cases} g_i(t, x(t)), & t \in (t_i, s_i], \\ x_0 + \int_0^t f(s, x(s)) ds, & t \in [0, t_1], \\ g_i(s_i, x(s_i)) + \int_{s_i}^t f(s, x(s)) ds, & t \in (s_i, t_{i+1}], \end{cases} \\ & \quad i = 0, 1, 2, 3, \dots, m. \end{aligned} \quad (4)$$

Assume that $x(t)$ and $\bar{x}(t)$ are the two solutions of (2) satisfying the initial conditions $x(t_0 + 0; t_0, x_0) = x_0$ and $\bar{x}(t_0 + 0; t_0, \bar{x}_0) = \bar{x}_0$, respectively. Now, referring to [14], let us define the stability of solutions in the sense of Lyapunov.

Definition 2 (see [14]). The solution $\bar{x}(t) = x(t, t_0, \bar{x}_0)$ of (2) is said to be stable, if, for each $\epsilon > 0$, $\exists$ a $\delta = \delta(t_0, \epsilon) > 0$ such

that, for any solution $x(t) = x(t, t_0, x_0)$ of (2), the inequality $\|x_0 - \bar{x}_0\| \leq \delta \Rightarrow \|x(t) - \bar{x}(t)\| < \epsilon$, for all $t \geq t_0$.

Definition 3 (see [14]). The solution $\bar{x}(t) = x(t, t_0, \bar{x}_0)$ of (2) is said to be uniformly stable, if, for each $\epsilon > 0$, $\exists$ a $\delta = \delta(\epsilon) > 0$ such that, for any solution $x(t) = x(t, t_0, x_0)$ of (2), the inequality $\|x_0 - \bar{x}_0\| \leq \delta \Rightarrow \|x(t) - \bar{x}(t)\| < \epsilon$, for all $t \geq t_0$.

Definition 4 (see [14]). The solution $\bar{x}(t) = x(t, t_0, \bar{x}_0)$ of (2) is said to be uniformly asymptotically stable, if, for each $\epsilon > 0$, $\exists$ a $\delta = \delta(\epsilon) > 0$ and a $\Gamma = \Gamma(\epsilon) > 0$ such that, for any solution $x(t) = x(t, t_0, x_0)$ of (2), the inequality $\|x_0 - \bar{x}_0\| \leq \delta \Rightarrow \|x(t) - \bar{x}(t)\| < \epsilon$, for all $t \geq t_0 + \Gamma$.

Let us introduce the sets

$$\begin{aligned} G_i &= \{(t, x, \bar{x}) \in [0, T] \times R \times R : t \in (s_i, t_{i+1}]\} \\ i &= 0, 1, 2, 3, \dots, m \quad \text{with } G = \bigcup_{i=0}^T G_i, \\ H_i &= \{(t, x, \bar{x}) \in [0, T] \times R \times R : t \in (t_i, s_i]\} \\ i &= 0, 1, 2, 3, \dots, m \quad \text{with } H = \bigcup_{i=0}^T H_i. \end{aligned} \quad (5)$$

Definition 5. A function $V : [0, T] \times R \times R \rightarrow R_+$ is said to belong to class V_0 if

- (i) V is continuous in G_i , $i = 0, 1, 2, \dots, m$;
- (ii) V is locally Lipschitz continuous in its second and third argument on each of G_i , $i = 0, 1, 2, \dots, m$;
- (iii) $V(t, \bar{x}, \bar{x}) = 0$;
- (iv) $V(t + 0, g_i(t, x), g_i(t, \bar{x})) \leq V(t, x, \bar{x})$ for each $(t, x, \bar{x}) \in H_i$, $i = 0, 1, 2, \dots, m$;
- (v) for $(t, x, \bar{x}) \in G_i$, one defines $D^+V(t, x, \bar{x}) = \lim_{h \rightarrow 0} \sup (1/h) [V(t+h, x+h f(t, x), \bar{x}+h \bar{x} f(t, \bar{x})) - V(t, x, \bar{x})]$;
- (vi) for s_i in $t_i < s_i \leq t_{i+1}$ in system (2), $V(s_i - 0, x, \bar{x}) = V(s_i, x, \bar{x})$ and $V(s_i + 0, x, \bar{x}) = \lim_{t \rightarrow s_i + 0} V(s_i, x, \bar{x})$.

Note that if $x(t)$ is a solution of system (2), then $D_{(2)}^+V(t, x, \bar{x}) = V_{(2)}'(t, x, \bar{x})$.

We will now use the following class of functions:

$$\begin{aligned} K &= \{a \in C[R_+, R_+] : \\ & \quad a(r) \text{ is strictly increasing and } a(0) = 0\}. \end{aligned} \quad (6)$$

3. Theoretical Results

Concerning the solution of system (3), referring to [10, 12], we introduce the following assumptions:

- (H1) $f \in C(J \times R, R)$;
- (H2) there exists a positive constant L_f such that $\|f(t, x_1) - f(t, x_2)\| \leq L_f \|x_1 - x_2\|$ for each $t \in [0, T]$ and all $x_1, x_2 \in R$;

- (H3) there exists a positive constant L_{g_i} , $i = 1, 2, 3, \dots, m$, such that $\|g_i(t, x_1) - g_i(t, x_2)\| \leq L_{g_i} \|x_1 - x_2\|$ for each $t \in [t_i, s_i]$ and all $x_1, x_2 \in R$. Also $\max\{L_{g_i}\} = L$ for $i = 1, 2, 3, \dots, m$;
- (H4) $f : J \times R \rightarrow R$ is strongly measurable for the first variable and is continuous for the second variable. There exists a positive constant L'_f and a nondecreasing function $W_f \in C([0, \infty), R_+)$ such that $|f(t, x)| \leq L'_f W_f(x)$ for each $t \in J$ and all $x \in R$.

The following is the result regarding the existence of unique solutions of system (3).

Theorem 6. Assume that (H1), (H2), and (H3) are satisfied. Then, problem (3) has unique solution $x \in PC^1(J, R)$ provided that

$$\max\{L_{g_i} + L_f(t_{i+1} - s_i), L_f t_1 : i = 1, 2, 3, \dots, m\} < 1. \quad (*)$$

Proof. Let $\Lambda : PC^1(J, R) \rightarrow PC^1(J, R)$ be defined by $\Lambda(x(0)) = x_0$, $\Lambda(x(t)) = g_i(t, x(t))$ for $t \in (t_i, s_i]$ and $\Lambda(x(t)) = g_i(s_i, x(s_i)) + \int_{s_i}^t f(s, x(s)) ds$, $t \in [s_i, t_{i+1}]$.

From the assumption, it is clear that Λ is well defined.

Moreover, for $x, y \in PC^1(J, R)$, $i = 1, 2, 3, \dots, m$, and $t \in [s_i, t_{i+1}]$, we get

$$\begin{aligned} \|\Lambda(x(t)) - \Lambda(y(t))\| &= \left\| g_i(s_i, x(s_i)) + \int_{s_i}^t f(s, x(s)) ds \right. \\ &\quad \left. - g_i(s_i, y(s_i)) - \int_{s_i}^t f(s, y(s)) ds \right\| \\ &\leq \|g_i(s_i, x(s_i)) - g_i(s_i, y(s_i))\| \\ &\quad + \left\| \int_{s_i}^t f(s, x(s)) ds - \int_{s_i}^t f(s, y(s)) ds \right\| \\ &\leq L_{g_i} \|x - y\|_{PC^1(J, R)} \\ &\quad + \int_{s_i}^t \|f(s, x(s)) - f(s, y(s))\| ds \\ &\leq L_{g_i} \|x - y\|_{PC^1(J, R)} \\ &\quad + \int_{s_i}^t L_f \|x(s) - y(s)\| ds \\ &\leq L_{g_i} \|x - y\|_{PC^1(J, R)} \\ &\quad + L_f \|x - y\|_{PC^1(J, R)} (t_{i+1} - s_i) \\ &= \{L_{g_i} + L_f(t_{i+1} - s_i)\} \|x - y\|_{PC^1(J, R)} \end{aligned} \quad (7)$$

and hence $\|\Lambda(x(t)) - \Lambda(y(t))\|_{C([s_i, t_{i+1}], R)} \leq \{L_{g_i} + L_f(t_{i+1} - s_i)\} \|x - y\|_{PC^1(J, R)}$.

Similarly, we obtain

$$\begin{aligned} &\text{for } t \in [t_i, s_i], \\ &\|\Lambda(x(t)) - \Lambda(y(t))\|_{C([t_i, s_i], R)} \leq L_{g_i} \|x - y\|_{PC^1(J, R)}, \\ &\text{for } t \in [0, t_1], \\ &\|\Lambda(x(t)) - \Lambda(y(t))\|_{C([0, t_1], R)} \leq L_f t_1 \|x - y\|_{PC^1(J, R)}. \end{aligned} \quad (8)$$

Thus, from the hypothesis (*) in the statement, we see that $\|\Lambda(x) - \Lambda(y)\|_{PC^1(J, R)} \leq \|x - y\|_{PC^1(J, R)}$ which implies that $\Lambda(\cdot)$ is a contraction map and problem (3) has unique solution in $PC^1(J, R)$. $\square$

Concerning the existence results of the solutions, the following result is stated without proof (referred to in [12] and proved in [10]).

Theorem 7. Assume that (H3) and (H4) are satisfied and the functions $g_i(\cdot, 0)$ are bounded. Then, problem (3) has at least one solution $x \in PC^1(J, R)$ provided that

$$\begin{aligned} &\limsup_{r \rightarrow \infty} \frac{W_f(r)}{r} \max\{2L_{g_i} + L'_f(t_{i+1} - s_i), \\ &\quad L'_f t_1 : i = 1, 2, 3, \dots, m\} < 1. \end{aligned} \quad (9)$$

Now, we establish the result for uniform stability of solutions of (2) by employing piecewise Lyapunov functions.

Theorem 8. Assume that (H1), (H2), and (H3) are satisfied. Let there exist functions $V \in V_0$ and $a, b \in K$ such that

$$a(\|x - \bar{x}\|) \leq V(t, x, \bar{x}) \leq b(\|x - \bar{x}\|), \quad (10)$$

$$t \in [0, T], \quad x, \bar{x} \in R,$$

$$V'_{(2)}(t, x, \bar{x}) \leq 0, \quad (t, x, \bar{x}) \in G_i \quad (11)$$

$$\text{for each } i = 1, 2, 3, \dots, m.$$

Then, the solution $\bar{x}(t)$ of system (2) is uniformly stable.

Proof. Let $\epsilon > 0$ be chosen. Choose $\delta = \delta(\epsilon) > 0$ so that $b(\delta) < a(\epsilon/(1 - L_g))$. Let $t_0 \in [0, T]$, $x_0, \bar{x}_0 \in R$, with $\|x_0 - \bar{x}_0\| < \delta$ and let $x(t) = x(t, t_0, x_0)$, $\bar{x}(t) = x(t, t_0, \bar{x}_0)$ be the solution of (2).

When $(t, x, \bar{x}) \in G_i$, that is, $t \in (s_i, t_{i+1}]$, from the properties of the function V and conditions (10) and (11), we get

$$\begin{aligned} &a\|x(t, t_0, x_0) - \bar{x}(t, t_0, \bar{x}_0)\| \\ &\leq V(t, x(t, t_0, x_0), \bar{x}(t, t_0, \bar{x}_0)) \leq V(t_0 + 0, x_0, \bar{x}_0) \\ &\leq b\|x_0 - \bar{x}_0\| < b(\delta) < a(\epsilon) \\ &\implies \|x(t, t_0, x_0) - \bar{x}(t, t_0, \bar{x}_0)\| < \epsilon; \quad t \in (s_i, t_{i+1}]. \end{aligned} \quad (12)$$

When $(t, x, \bar{x}) \in H_i$, that is, $t \in (t_i, s_i]$, from (10) and condition (iv) of Definition 5, we get

$$\begin{aligned} & a \|x(t, t_0, x_0) - \bar{x}(t, t_0, \bar{x}_0)\| \\ & \leq V(t, x(t, t_0, x_0), \bar{x}(t, t_0, \bar{x}_0)) \leq V(t, g_i(t, x), g_i(t, \bar{x})) \\ & \leq V(t_0, x_0, \bar{x}_0) \leq b(\delta) < a(\epsilon) \\ \implies & \|x(t, t_0, x_0) - \bar{x}(t, t_0, \bar{x}_0)\| < \epsilon; \quad t \in (t_i, s_i]. \end{aligned} \quad (13)$$

Thus, from inequalities (12) and (13), we find that, for each $\epsilon > 0$, $\exists$ a $\delta = \delta(\epsilon) > 0$ such that, for any solution $x(t) = x(t, t_0, x_0)$ of (2), the inequality $\|x_0 - \bar{x}_0\| \leq \delta \implies \|x(t) - \bar{x}(t)\| < \epsilon$ for $t \geq t_0$ and $t \in [0, T]$.

Hence, the solution $\bar{x}(t)$ of system (2) is uniformly stable. $\square$

Theorem 9. Assume that all the conditions of Theorem 8 except (II) hold and condition (II) is replaced by the following:

$$\begin{aligned} V'_{(2)}(t, x, \bar{x}) & \leq -c(\|x - \bar{x}\|), \quad (t, x, \bar{x}) \in G_i \\ & \text{for each } i = 1, 2, 3, \dots, m. \end{aligned} \quad (14)$$

Then, the solution $\bar{x}(t)$ of system (2) is uniformly asymptotically stable.

Proof. Let $\epsilon > 0$ be given and let the number $\eta = \eta(\epsilon) > 0$ be chosen so that $b(\eta) < a(\epsilon)$. Let $\alpha > 0$ be a positive constant such that $\alpha < \eta$. Let $\Gamma = \Gamma(\alpha, \epsilon) > 0$ be such that $\Gamma > b(\alpha)/c(\eta)$ and $t_0 + \Gamma \leq T$.

For any $t \in [t_0, T]$, denote $V_{t,\alpha}^{-1} = \{x \in R : V(t + 0, x, \bar{x}) \leq a(\alpha)\}$.

Also, from condition (10), for any $x, \bar{x} \in R$,

$$a(\|x - \bar{x}\|) \leq V(t + 0, x, \bar{x}) \leq a(\alpha) \implies \|x - \bar{x}\| \leq \alpha. \quad (15)$$

Therefore, $V_{t,\alpha}^{-1} = \{x \in R : \|x - \bar{x}\| \leq \alpha\}$.

It follows that for any $x_0 \in V_{t_0,\alpha}^{-1}$ we have $x(t; t_0, x_0) \in V_{t,\alpha}^{-1}$.

If possible, assume that, for each $t \in [t_0, t_0 + \Gamma]$, the inequality

$$\|x(t; t_0, x_0) - t_0 - \bar{x}(t; t_0, \bar{x}_0)\| \geq \eta \quad (16)$$

is valid.

Case 1. If $t \in [t_0, t_0 + \Gamma]$ such that $(t, x, \bar{x}) \in H_i$, then, from (16), we have

$$\begin{aligned} & \|x(t; t_0, x_0) - t_0 - \bar{x}(t; t_0, \bar{x}_0)\| \geq \eta \\ \implies & b(\eta) \leq b(\|x(t; t_0, x_0) - t_0 - \bar{x}(t; t_0, \bar{x}_0)\|) \leq b(\alpha) \\ \implies & \eta \leq \alpha, \end{aligned} \quad (17)$$

which is a contradiction to the assumption $\alpha < \eta$ and hence (16) is not valid.

Case 2. If $t \in [t_0, t_0 + \Gamma]$ such that $(t, x, \bar{x}) \in G_i$, then, from (14) and (16), we have

$$\begin{aligned} & V'_{(2)}(t, x, \bar{x}) \leq -c(\|x - \bar{x}\|), \quad (t, x, \bar{x}) \in G_i \\ \implies & V(t_0 + \Gamma, x(t_0 + \Gamma; t_0, x_0), \bar{x}(t_0 + \Gamma; t_0, \bar{x}_0)) \\ & \quad - V(t_0 + 0, x_0, \bar{x}_0) \\ & \leq - \int_{t_0}^{t_0 + \Gamma} c(\|x(s; t_0, x_0) - \bar{x}(s; t_0, \bar{x}_0)\|) ds \\ \implies & V(t_0 + \Gamma, x(t_0 + \Gamma; t_0, x_0), \bar{x}(t_0 + \Gamma; t_0, \bar{x}_0)) \\ & \leq V(t_0 + 0, x_0, \bar{x}_0) - \int_{t_0}^{t_0 + \Gamma} c(\eta) ds \\ & \leq b(\alpha) - \Gamma c(\eta) < 0, \end{aligned} \quad (18)$$

which is a contradiction to the assumption $\Gamma > b(\alpha)/c(\eta)$ and hence (16) is not valid.

Thus, we see that in both cases whether $(t, x, \bar{x}) \in G_i$ or $(t, x, \bar{x}) \in H_i \exists t^* \in [t_0, t_0 + \Gamma]$ such that $\|x(t; t_0, x_0) - t_0 - \bar{x}(t; t_0, \bar{x}_0)\| < \eta$.

Then, for $t^* \in [t_0, t_0 + \Gamma]$ and hence for any $t \geq t_0 + \Gamma$, we have

$$\begin{aligned} & a(\|x - \bar{x}\|) \leq V(t; x(t), \bar{x}(t)) \leq V(t^*; x(t^*), \bar{x}(t^*)) \\ & \leq b(\|x(t^*; t_0, x_0) - \bar{x}(t^*; t_0, \bar{x}_0)\|) \\ & < b(\eta) < a(\epsilon) \\ \implies & \|x(t; t_0, x_0) - \bar{x}(t; t_0, \bar{x}_0)\| < \epsilon \\ & \text{for } t \geq t_0 + \Gamma. \end{aligned} \quad (19)$$

Thus, the solution $\bar{x}(t)$ of system (2) is uniformly asymptotically stable. $\square$

4. Example

Let $J = [0, 2]$ and $0 = t_0 = s_0 < t_1 = 1 < s_2 = 2$. Denote $f(t, x(t)) = 1/(1 + |x(t)|)$ for $t \in (0, 1]$ and $g_1(t, x(t)) = |x(t)|/(2 + |x(t)|)$ for $t \in (1, 2]$. Also define functions $a, b \in K$ as $a(t) = (1/2)t$ and $b(t) = (3/2)t$.

Here, $(t, x, \bar{x}) \in G_1$; that is, for $t \in (0, 1]$,

$$\begin{aligned} |f(t, x_1(t)) - f(t, x_2(t))| &= \left| \frac{1}{1 + |x_1(t)|} - \frac{1}{1 + |x_2(t)|} \right| \\ &= \left| \frac{|x_2(t)| - |x_1(t)|}{(1 + |x_2(t)|)(1 + |x_1(t)|)} \right| \\ &\leq ||x_1(t)| - |x_2(t)|| \\ &\leq |x_1(t) - x_2(t)|. \end{aligned} \quad (20)$$

Therefore, we have $L_f = 1$. Similarly, it can be seen that, for $t \in (1, 2]$, $L_{g_1} = 1/2$.

Now, consider the system

$$\begin{aligned} x'(t) &= \frac{1}{1 + |x(t)|}, \quad t \in (0, 1], \\ x(t) &= \frac{|x(t)|}{2 + |x(t)|}, \quad t \in [1, 2]. \end{aligned} \quad (21)$$

Let $V(t, x, \bar{x}) = \|x(t) - \bar{x}(t)\|$. Without loss of generality, we assume that $\|x(t)\| \geq \|\bar{x}(t)\|$.

Clearly, $V(t, \bar{x}, \bar{x}) = 0$. Also V is continuous and locally Lipschitz in second and third argument on G_1 .

Also, for $(t, x, \bar{x}) \in G_1$,

$$\begin{aligned} V'_{(2)}(t, x, \bar{x}) &= [x' - \bar{x}'] \text{Sign}(x - \bar{x}) \\ &= \left\{ \frac{1}{[1 + |x(t)|]} - \frac{1}{[1 + |\bar{x}(t)|]} \right\} \\ &= \left\{ \frac{|\bar{x}(t)| - |x(t)|}{[1 + |x(t)|][1 + |\bar{x}(t)|]} \right\} \leq 0. \end{aligned} \quad (22)$$

For $(t, x, \bar{x}) \in H_1$, that is, for $t \in (1, 2]$,

$$\begin{aligned} V(t + 0, g_i(t, x), g_i(t, \bar{x})) &\in H_i \\ &= V\left(t + 0, \frac{|x(t)|}{2 + |x(t)|}, \frac{|\bar{x}(t)|}{2 + |\bar{x}(t)|}\right) \\ &= \left\| \frac{|x(t)|}{2 + |x(t)|} - \frac{|\bar{x}(t)|}{2 + |\bar{x}(t)|} \right\| \\ &= \left\| \frac{2|x(t)| - 2|\bar{x}(t)|}{[2 + |x(t)|][2 + |\bar{x}(t)|]} \right\| \leq \frac{2}{4} \|x(t) - \bar{x}(t)\| \\ &\leq \frac{1}{2} \|x(t) - \bar{x}(t)\| \leq V(t, x, \bar{x}). \end{aligned} \quad (23)$$

Also, $a(\|x - \bar{x}\|) = (1/2)\|x - \bar{x}\| \leq \|x - \bar{x}\| = V(t, x, \bar{x}) \leq (3/2)\|x - \bar{x}\| = b(\|x - \bar{x}\|)$.

Thus, we see that all the conditions of Theorem 8 are satisfied and hence system (21) is uniformly stable.

5. Conclusion

Stability of solutions of impulsive ordinary differential equations with instantaneous impulses has been discussed extensively in the past [1–9]. Motivated by the recent work [10–13], in this paper, a new class of ordinary differential equations with noninstantaneous impulses has been studied and uniform stability and uniform asymptotic stability of solutions of such systems are investigated by using piecewise Lyapunov functions.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
