1. Introduction

In [1, 2], differential geometric formulae of three-dimensional (3D) domains and two-dimensional (2D) surface are defined in curvilinear ordinates, respectively. Besides, there are some scientists, such as Pobedrya [3], Vekua [4], and Nikabadze [5], who have some contributions in this field. In this paper, we assume that the three-dimensional elastic shell with equal thickness comprises a series of overlying surfaces like middle surface. Thus, the differential geometric relations between 3D elasticity and 2D middle surface are provided which are very important for forming 2D shell model from 3D equations (cf. [6–9]). Concretely, the metric tensor, the determinant of metric matrix field, the Christoffel symbols, and Riemann tensors on the 3D domain are expressed by those on the 2D middle surface, which are featured by the asymptotic expressions with respect to the variable in the direction of thickness of the shell. In Section 3, two kinds of special shells, that is, hemispherical shell and semicylindrical shell, are provided as the examples.

In this section, we mainly introduce some notations. Our notations are essentially borrowed from [2]. In what follows, Latin indices and exponents \(i, j, k, \ldots\) take their values in the set \(\{1, 2, 3\}\), whereas Greek indices and exponents \(\alpha, \beta, \gamma, \ldots\) take their values in the set \(\{1, 2\}\). In addition, the repeated index summation convention is systematically used. The Euclidean scalar product and the exterior product of \(\vec{a}, \vec{b} \in \mathbb{R}^3\) are noted by \(\vec{a} \cdot \vec{b}\) and \(\vec{a} \times \vec{b}\), respectively. Let \(\omega\) (cf. Figure 1) be an open, bounded, connected subset of \(\mathbb{R}^2\), the boundary \(\gamma = \partial\omega\) of which is Lipschitz-continuous, and let \(\gamma = \gamma_0 \cup \gamma_1\) with \(\gamma_0 \cap \gamma_1 = \emptyset\). Let \(y = (y_\alpha)\) denote a generic point in the set \(\overline{\omega}\) (i.e., closure of \(\omega\)) and let \(\partial_{y_\alpha} = \partial/\partial y_\alpha\). Let there be given an injective mapping \(\tilde{\theta} \in C^3(\overline{\omega}; \mathbb{R}^2)\), such that the two vectors

\[
\hat{a}_\alpha(y) = \partial_{y_\alpha}\tilde{\theta}(y)
\]  

are linearly independent at all points \(y \in \overline{\omega}\). These two vectors thus span the tangent plane to the surface

\[
S = \tilde{\theta}(\overline{\omega})
\]

at the point \(\tilde{\theta}(y)\), and the unit vector

\[
\hat{a}_3(y) = \frac{\hat{a}_1(y) \times \hat{a}_2(y)}{|\hat{a}_1(y) \times \hat{a}_2(y)|}
\]
is normal to $S$ at the point $\vec{\theta}(y)$. These vectors $\vec{a}_i(y)$ constitute the covariant basis at the point $\theta(y)$, whereas the vectors $\vec{a}^i(y)$ defined by the relations

$$\vec{a}^i(y) \cdot \vec{a}_j(y) = \delta^i_j$$  \hspace{1cm} (4)

constitute the contravariant basis at the point $\theta(y)$, where $\delta^i_j$ is the Kronecker symbol (note that $\vec{a}^3(y) = \vec{a}_3(y)$ and the vector $\vec{a}^\alpha(y)$ is also in the tangent plane to $S$ at $\vec{\theta}(y)$) (cf. Figure 1).

The covariant and contravariant components $a_{\alpha\beta}$ and $a^{\alpha\beta}$ of the metric tensor of $S$, the Christoffel symbol $\Gamma^\sigma_{\alpha\beta}$ on $S$, the covariant and mixed components $b_{\alpha\beta}$ and $b^\sigma_{\alpha\beta}$ of the curvature tensor of $S$, and the covariant of the third fundamental form on $S$ are then defined as follows (the explicit dependence on the variable $y \in \omega$ is henceforth dropped):

$$a_{\alpha\beta} := \vec{a}_\alpha \cdot \vec{a}_\beta,$$

$$a^{\alpha\beta} := \vec{a}^\alpha \cdot \vec{a}^\beta,$$

$$(a^{\alpha\beta}) = (a_{\alpha\beta})^{-1},$$

$$\vec{a}^\alpha = a^{\alpha\beta} \vec{a}_\beta,$$

$$(\vec{a}^\alpha, \vec{a}^\beta, \vec{a}^\gamma) = (\vec{a}_\alpha, \vec{a}_\beta, \vec{a}_\gamma),$$

$$\Gamma^\sigma_{\alpha\beta} := \vec{a}_\sigma \cdot \partial_{\alpha} \vec{a}_\beta,$$

$$\Gamma_{\alpha\beta}^\sigma := \vec{a}^\sigma \cdot \partial_{\alpha} \vec{a}_\beta,$$

$$b_{\alpha\beta} := \vec{a}_\beta \cdot \partial_{\alpha} \vec{a}_3,$$

$$b^\sigma_{\alpha\beta} := \vec{a}_3 \cdot \partial_{\alpha} \vec{a}_\beta,$$

$$c_{\alpha\beta} := \vec{a}_\alpha \vec{a}_3 \cdot \partial_{\beta} \vec{a}_3,$$  \hspace{1cm} (5)

where $(a_{\alpha\beta})$ is symmetric and positive-definite matrix field, $(b_{\alpha\beta})$ and $(c_{\alpha\beta})$ are symmetric matrix fields. The determinants of metric tensor, curvature tensor, and the third fundamental form are

$$a := \det(a_{\alpha\beta}),$$

$$b := \det(b_{\alpha\beta}),$$

$$c := \det(c_{\alpha\beta}).$$  \hspace{1cm} (8)

Thus, the Riemann tensors on the middle surface $S$ are defined by (cf. [10])

$$(\hat{R}^\sigma_{\alpha\beta} + \hat{R}^\sigma_{\gamma\delta} \Gamma^\delta_{\alpha\beta} = \partial_\gamma \Gamma^\sigma_{\alpha\beta} - \partial_\beta \Gamma^\sigma_{\alpha\gamma} + \Gamma^\lambda_{\alpha\beta} \Gamma^\sigma_{\lambda\gamma} - \Gamma^\lambda_{\alpha\gamma} \Gamma^\sigma_{\lambda\beta}.$$  \hspace{1cm} (9)

Then, the covariant components of Riemann tensors on $S$ are defined by

$$\hat{R}_{\alpha\beta\gamma} = a^{\rho\sigma} \hat{R}^\rho_{\alpha\beta}.$$  \hspace{1cm} (10)

Assume that there is a shell $\vec{\Omega}^\xi$ (cf. Figure 2) with middle surface $S = \vec{\theta}(\omega)$ and whose thickness $2\varepsilon > 0$ is arbitrarily small. Hence, for each $\varepsilon > 0$, the reference configuration of the shell is $\vec{\Omega}^\xi = \vec{\theta}(\omega \times [-\varepsilon, \varepsilon])$, where $\vec{\omega} = \omega \times [-\varepsilon, \varepsilon]$; that is,

$$\vec{\theta}(y, \xi) = \vec{\theta}(y) + \xi \vec{a}_3(y), \hspace{1cm} -\varepsilon \leq \xi \leq \varepsilon.$$  \hspace{1cm} (11)

In this sense, the 3D elastic shell with equal thickness comprises a series of overlying surfaces like middle surface. The top and bottom faces of $\vec{\theta}(\vec{\Omega}^{\varepsilon})$ are $\Gamma_t = \vec{\theta}(\omega \times \{+\varepsilon\})$ and $\Gamma_b = \vec{\theta}(\omega \times \{-\varepsilon\})$. The lateral face is $\Gamma_l = \Gamma_0 \cup \Gamma_1$, where
\[ \Gamma_0 = \tilde{\theta}(y_0) \times [-\epsilon, +\epsilon], \quad \Gamma_1 = \tilde{\theta}(y_1) \times [-\epsilon, +\epsilon] \text{ (cf. [11]).} \]

Let \( x = (x_i) = (y_1, y_2, \xi) \) denote a generic point in the set \( \overline{\Omega} \). The mapping \( \tilde{\Theta} : \overline{\Omega} \to \mathbb{R}^3 \) is injective and the three vectors

\[ \tilde{g}_i(x) = \partial_i \tilde{\Theta}(x) \]

are linearly independent at all points \( x \in \overline{\Omega} \). The vectors \( \tilde{g}_i(y) \) are defined by the relations

\[ \tilde{g}_i(x) \cdot \tilde{g}_j(x) = \delta_{ij}. \]

These relations constitute the contravariant basis at the point \( \tilde{\Theta}(x) \in S \). The covariant and contravariant components \( g_{ij} \) and \( g^{ij} \) of the metric tensor of \( \tilde{\Theta}(\overline{\Omega}) \), the Christoffel symbols \( \Gamma_{ij,k} \) and \( \Gamma_{ijkl} \) on \( \tilde{\Theta}(\overline{\Omega}) \) are then defined as follows (the explicit dependence on the variable \( x \in \overline{\Omega} \) is henceforth dropped):

\[ g_{ij} = \tilde{g}_i \cdot \tilde{g}_j, \]
\[ g^{ij} = \tilde{g}^i \cdot \tilde{g}^j, \]
\[ \Gamma_{ij,k} = \tilde{g}_k \cdot \partial_i \tilde{g}_j, \]
\[ \Gamma_{ijkl} = \tilde{g}^{kl} \Gamma_{ij,kl}. \]

The determinant of metric tensor is

\[ g = \det (g_{ij}). \]

Thus, the Riemann tensors on \( \tilde{\Theta}(\overline{\Omega}) \) are defined by

\[ R_{kl}^{ij} = \partial_i \Gamma_{kl,j} - \partial_k \Gamma_{il,j} + \Gamma_{ik,l} \Gamma_{jl} - \Gamma_{il,k} \Gamma_{jl}. \]

Then, the covariant components of Riemann tensors on \( \tilde{\Theta}(\overline{\Omega}) \) are defined by

\[ R_{ijk} = g_{ip} R_{jk}^{ip}. \]

### 2. Main Results

**Theorem 1.** Assume that there is a shell with middle surface \( S = \tilde{\theta}(\omega) \) whose thickness \( 2 \epsilon > 0 \) is arbitrarily small, where \( \omega \) is open, bounded, and connected in \( \mathbb{R}^2 \) with Lipschitz-continuous boundary \( y = \partial \omega \) and \( \tilde{\theta} \in C^3(\omega; \mathbb{R}^3) \). Hence, for each \( \epsilon > 0 \), the reference configuration of the shell is \( \tilde{\Theta}(\overline{\Omega}) \), where \( \overline{\Omega} = \omega \times [-\epsilon, \epsilon] \); that is,

\[ \tilde{\Theta}(y, \xi) = \tilde{\theta}(y) + \xi \tilde{a}_3(y). \]

The metric tensors on \( \tilde{\Theta}(y, \xi) \) and \( \tilde{\theta}(\overline{\omega}) \) are \( g_{ij} \) and \( a_{\alpha\beta} \), respectively. \( b_{\alpha\beta} \) and \( c_{\alpha\beta} \) are the second and third fundamental forms on \( \tilde{\theta}(\overline{\omega}) \). Then, the following differential geometric relations hold:

\[ a_{\alpha\beta} = a_{\beta\alpha} - 2 \xi b_{\alpha\beta} + \xi^2 c_{\alpha\beta}, \]
\[ g_{\alpha3} = g_{3\alpha} = 0, \]
\[ g_{33} = 1, \]
\[ \alpha, \beta = 1, 2, \xi \in [-\epsilon, \epsilon]. \]

**Proof.**

\[ g_{\alpha\beta} = \tilde{g}_\alpha \cdot \tilde{g}_\beta = \partial_\alpha \tilde{\Theta} \cdot \partial_\beta \tilde{\Theta} \]
\[ = \partial_\alpha (\tilde{\theta} + \xi \tilde{a}_3) \cdot \partial_\beta (\tilde{\theta} + \xi \tilde{a}_3) \]
\[ = \partial_\alpha \tilde{\theta} \cdot \partial_\beta \tilde{\theta} + \partial_\alpha \tilde{\theta} \cdot \partial_\beta (\xi \tilde{a}_3) + \partial_\alpha (\xi \tilde{a}_3) \cdot \partial_\beta \tilde{\theta} \]
\[ + \partial_\alpha (\xi \tilde{a}_3) \cdot \partial_\beta (\xi \tilde{a}_3) \]
\[ = a_{\alpha} \cdot a_{\beta} + \xi a_{\alpha} \cdot \partial_\beta \tilde{a}_3 + \xi \partial_\alpha a_3 \cdot a_{\beta} + \xi^2 \partial_\alpha \tilde{a}_3 \cdot \partial_\beta \tilde{a}_3. \]
Submitting (1) and (5)–(7) into (20), based on the symmetry of $b_{\alpha\beta}$, we have
\begin{align}
g_{\alpha\beta} &= a_{\alpha\beta} - 2\xi b_{\alpha\beta} + \xi^2 c_{\alpha\beta}, \\
g_{\alpha\beta} &= 33 = \tilde{a}_3 \cdot \tilde{a}_3 = \tilde{a}_3 \tilde{\Theta} \cdot \tilde{a}_3 \tilde{\Theta}
\end{align}

= $\tilde{a}_3 \cdot \tilde{a}_3 (\tilde{\Theta} + \xi \tilde{a}_3) \cdot \tilde{a}_3 (\tilde{\Theta} + \xi \tilde{a}_3)
\begin{align}
= \tilde{a}_3 \cdot \tilde{a}_3 \tilde{\Theta} + \tilde{a}_3 \cdot \tilde{a}_3 (\xi \tilde{a}_3) = \tilde{a}_3 \cdot \tilde{a}_3 = \xi \tilde{a}_3 \cdot \tilde{a}_3.
\end{align}

From the definition of $a_3$, we know
\begin{align}
\tilde{a}_3 \cdot \tilde{a}_3 &= 0, \\
\tilde{a}_3 \cdot \tilde{a}_3 &= 1.
\end{align}

Then,
\begin{align}
\tilde{a}_3 \cdot \tilde{a}_3 (\tilde{\Theta} + \xi \tilde{a}_3) = 2\tilde{a}_3 \cdot \tilde{a}_3 \tilde{\Theta} + \tilde{a}_3 = 0.
\end{align}

Thus,
\begin{align}
\tilde{a}_3 \cdot \tilde{a}_3 (\tilde{a}_3) = 0.
\end{align}

Submitting (23)–(25) into (22), we get
\begin{align}
g_{33} = 0. 
\end{align}

Similarly,
\begin{align}
g_{\alpha\beta} &= 0, \\
g_{33} &= \tilde{a}_3 \cdot \tilde{a}_3 = \tilde{a}_3 \tilde{\Theta} \cdot \tilde{a}_3 \tilde{\Theta}
\end{align}

= $\tilde{a}_3 \cdot \tilde{a}_3 (\tilde{\Theta} + \xi \tilde{a}_3) \cdot \tilde{a}_3 (\tilde{\Theta} + \xi \tilde{a}_3)
\begin{align}
= \tilde{a}_3 \cdot \tilde{a}_3 \tilde{\Theta} + \tilde{a}_3 \cdot \tilde{a}_3 (\xi \tilde{a}_3) = \tilde{a}_3 \cdot \tilde{a}_3 = \xi \tilde{a}_3 \cdot \tilde{a}_3.
\end{align}

Since $(g^{ij}) = (g_{ij})^{-1}$, the contravariant components of $g^{ij}$ should be expressed as follows.

\textbf{Theorem 2.} Under the assumptions of Theorem 1, let $g^{ij}$ be the contravariant components of the metric tensors on $\tilde{\Theta}(y, \xi)$. Then, the following formulae hold:
\begin{align}
g^{11} &= g^{-1} (a_{22} - 2\xi b_{22} + \xi^2 c_{22}), \\
g^{12} &= g^{21} = -g^{-1} (a_{12} - 2\xi b_{12} + \xi^2 c_{12}), \\
g^{22} &= g^{-1} (a_{11} - 2\xi b_{11} + \xi^2 c_{11}), \\
g^{33} &= g^{33} = 0,
\end{align}

where $g = \det(g_{ij}) = (a_{11} - 2\xi b_{11} + \xi^2 c_{11})(a_{22} - 2\xi b_{22} + \xi^2 c_{22}) - (a_{12} - 2\xi b_{12} + \xi^2 c_{12})^2$.
Submitting (35) and (7) into (33), we get
\[
\Gamma_{a\beta,3} = b_{\alpha\beta} - \xi c_{a\beta}, \\
\Gamma_{a3,\sigma} = \vec{g}_{\sigma} \cdot \partial_3 \vec{a}_{a} = \vec{g}_{\sigma} \cdot \partial_3 \vec{a}_{a}.
\]
Similarly,
\[
\Gamma_{3\sigma,a} = -b_{a\sigma} + \xi c_{a\sigma}, \\
\Gamma_{33,a} = \vec{g}_{a} \cdot \partial_3 \vec{a}_{3} = \vec{g}_{a} \cdot \partial_3 \vec{a}_{3},
\]
From Gaussian formula of coordinates systems (cf. [7]), we have similar relations.

**Theorem 4.** Under the assumptions of Theorem 1, let \( \Gamma_{ij}^{\sigma} \) be the Christoffel symbols on \( \vec{\theta}(y, \xi) \). Then, the following formulae hold:
\[
\Gamma_{a\beta}^{\sigma} = g^{\sigma\tau} \left( \hat{\Gamma}_{a\beta,\tau} + \xi \hat{\alpha}_{\tau} - \hat{\beta}_{\tau} \hat{\alpha}_{a} - \hat{\alpha}_{\tau} \hat{\beta}_{a} + \xi \hat{\beta}_{a} \hat{\alpha}_{\tau} \right),
\]
\[
\Gamma_{a3}^{\sigma} = b_{a\sigma} - \xi c_{a\sigma}, \\
\Gamma_{33}^{\sigma} = \Gamma_{33}^{\sigma} = 0,
\]
\[
\alpha, \beta, \sigma = 1, 2.
\]

**Proof.** Because of (13), we have
\[
\Gamma_{a\beta}^{\sigma} = g^{\sigma\tau} \Gamma_{a\beta,\tau}^{\sigma} = g^{\sigma3} \Gamma_{a3,\beta}^{3} = g^{\sigma\tau} \Gamma_{a\beta,\tau}^{3}, \\
\Gamma_{a3}^{3} = \Gamma_{33}^{\sigma} = 0,
\]
\[
\Gamma_{a3}^{3} = g^{a\ell} \Gamma_{33,\ell}^{\sigma} = g^{\sigma3} \Gamma_{a3,\tau}^{\sigma} = g^{\sigma3} \Gamma_{a3,\tau}^{3} = \Gamma_{a3,\tau}^{\sigma},
\]
Thus, formula (38) can be derived easily from the results of Theorems 2 and 3.

**Theorem 5.** Under the assumptions of Theorem 1, let \( R_{i\ell kj}^{\sigma} \) and \( \hat{R}_{\alpha\beta}^{\sigma} \hat{R}_{\alpha\beta}^{\sigma} \) be the Riemann tensors on \( \vec{\theta}(y, \xi) \) and \( \vec{\theta}(y) \), respectively. Then, the following formulae hold:
\[
R_{i\ell kj}^{\sigma} = 0, \\
R_{i\ell k j}^{\sigma} = 0, \\
\alpha, \beta, i,j,k,l \in 1, 2, 3
\]

**Proof.** As we all know, formula (40) has been proven by Ciarlet in [12] (cf. Theorem 1.6-1). We only should prove formula (41).

From Gaussian formula of coordinate systems (cf. [7]), we have
\[
\partial_{\beta} \hat{a}_{\alpha} = \left( \partial_{\beta} \hat{a}_{\alpha} \cdot \hat{a}_{\lambda}^{\lambda} \right) \hat{a}_{\lambda} + \left( \partial_{\beta} \hat{a}_{\alpha} \cdot \hat{a}_{\lambda}^{3} \right) \hat{a}_{3},
\]
\[
= \hat{\Gamma}_{a\beta}^{\sigma} \hat{a}_{\lambda} + b_{a\beta} \hat{a}_{\lambda},
\]
Submitting \( \partial_{\beta} \hat{a}_{\alpha} \) into (42), we have
\[
\partial_{\beta} \hat{a}_{\alpha} = \left( \partial_{\beta} \hat{a}_{\alpha} \cdot \hat{a}_{\lambda}^{\lambda} \right) \hat{a}_{\lambda} + \left( \partial_{\beta} \hat{a}_{\alpha} \cdot \hat{a}_{\lambda}^{3} \right) \hat{a}_{3},
\]
\[
= \hat{\Gamma}_{a\beta}^{\sigma} \hat{a}_{\lambda} + b_{a\beta} \hat{a}_{\lambda},
\]
Similarly,
\[
\partial_{\beta} \hat{a}_{\alpha} = \left( \partial_{\beta} \hat{a}_{\alpha} \cdot \hat{a}_{\lambda}^{\lambda} \right) \hat{a}_{\lambda} + \left( \partial_{\beta} \hat{a}_{\alpha} \cdot \hat{a}_{\lambda}^{3} \right) \hat{a}_{3},
\]
\[
= \hat{\Gamma}_{a\beta}^{\sigma} \hat{a}_{\lambda} + b_{a\beta} \hat{a}_{\lambda}.
\]

Thus, formula (38) can be derived easily from the results of Theorems 2 and 3.
Because of $\partial_\beta \tilde{a}_\alpha = \partial_\alpha \tilde{a}_\beta$, we can deduce by (44)-(45) that

$$0 = \left( \partial_\beta \Gamma^\sigma_{\alpha\beta} - \partial_\beta \Gamma^\sigma_{\alpha\gamma} + \Gamma^\lambda_{\alpha\beta} \Gamma^\sigma_{\lambda\gamma} - \Gamma^\lambda_{\alpha\gamma} \Gamma^\sigma_{\lambda\beta} - b_{\alpha\beta} b_{\gamma}^\sigma + b_{\alpha\gamma} b_{\beta}^\sigma \right) \tilde{a}_\sigma + \left( \Gamma^\lambda_{\alpha\beta} \tilde{b}_{\lambda\gamma} - \Gamma^\lambda_{\alpha\gamma} \tilde{b}_{\lambda\beta} + \partial_\gamma b_{\alpha\beta} - \partial_\beta b_{\alpha\gamma} \right) \cdot \tilde{a}_3. \tag{46}$$

Since $\tilde{a}_\sigma$ and $\tilde{a}_3$ are linearly independent, we have

$$\partial_\beta \tilde{a}_\beta - \partial_\beta \tilde{a}_\beta = \Gamma^\gamma_{\alpha\beta} \tilde{a}_\gamma - \Gamma^\gamma_{\alpha\gamma} \tilde{a}_\beta = b_{\alpha\beta} b_{\gamma}^\gamma - b_{\alpha\gamma} b_{\beta}^\gamma, \tag{47}$$

$$\partial_\beta b_{\alpha\beta} - \Gamma^\gamma_{\alpha\beta} \tilde{b}_{\beta\gamma} = \partial_\gamma b_{\alpha\beta} - \tilde{b}_{\beta\gamma}. \tag{48}$$

Thus, formula (41) has been proven. \qed

3. Examples

3.1. Hemispherical Shell. Assume that the middle surface $S$ of shell is a hemispherical surface (see Figure 3) whose reference equation is given by the mapping $\tilde{\theta}(\tilde{\omega})$ defined by

$$\tilde{\theta}(y_1, y_2) = (r \cos y_1 \sin y_2, r \sin y_1 \sin y_2, r \cos y_2), \tag{49}$$

where $r = 1$ m is the radius of the middle surface $S$, $0 \leq y_1 < 2\pi$ is longitude, and $0 \leq y_2 < \pi/2$ is colatitude. The thickness of the middle surface $S$ is $2\varepsilon$ where $\varepsilon$ is the semithickness.

Then,

$$\tilde{a}_1 = \partial_1 \tilde{\theta} = (-r \sin y_1 \sin y_2, r \cos y_1 \sin y_2, 0), \tag{50}$$

$$\tilde{a}_2 = \partial_2 \tilde{\theta} = (r \cos y_1 \cos y_2, r \sin y_1 \cos y_2, -r \sin y_2). \tag{51}$$

Hence, the covariant and contravariant components of the metric tensor on $S$ are given by

$$a_{\alpha\beta} = \begin{bmatrix} r^2 \sin^2 y_2 & 0 \\ 0 & r^2 \end{bmatrix}, \tag{52}$$

$$c_{\alpha\beta} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \tag{53}$$

Then,

$$\tilde{a}_3 = \frac{\tilde{a}_1 \times \tilde{a}_2}{|\tilde{a}_1 \times \tilde{a}_2|} = (\cos y_1 \sin y_2, \sin y_1 \sin y_2, \cos y_2), \tag{54}$$

$$\partial_1 \tilde{a}_3 = (-\sin y_1 \sin y_2, \cos y_1 \sin y_2, 0), \tag{55}$$

$$\partial_2 \tilde{a}_3 = (\cos y_1 \cos y_2, \sin y_1 \cos y_2, -\sin y_2), \tag{56}$$

$$\partial_1 \tilde{a}_3 = (-\cos y_1 \sin y_2, -\sin y_1 \sin y_2, 0), \tag{57}$$

$$\partial_2 \tilde{a}_3 = (\cos y_1 \cos y_2, -\sin y_1 \cos y_2, 0). \tag{58}$$

The Christoffel symbols on $S$ are as follows:

$$\tilde{\Gamma}_1^{1,2} = -r^2 \sin y_2 \cos y_2, \tag{59}$$

$$\tilde{\Gamma}_1^{2,1} = r^2 \sin y_2 \cos y_2, \tag{60}$$

other $\tilde{\Gamma}_1^{\alpha\beta} = 0,$ \tag{61}

$$\tilde{\Gamma}_2^{1,2} = \cot y_2, \tag{62}$$

$$\tilde{\Gamma}_1^{2,2} = -\sin y_2 \cos y_2, \tag{63}$$

other $\tilde{\Gamma}_2^{\alpha\beta} = 0.$ \tag{64}

The Riemann tensors on $S$ are as follows:

$$\tilde{R}_{1212} = \tilde{R}_{2121} = -r^2 \sin^2 y_2, \tag{65}$$

$$\tilde{R}_{1221} = \tilde{R}_{2112} = r^2 \sin^2 y_2, \tag{66}$$

other $\tilde{R}_{\alpha\beta\gamma\delta} = 0.$ \tag{67}
Hence, for each \( \varepsilon > 0 \), the reference configuration of the shell with middle surface \( S = \mathcal{R}(\omega) \) is \( \mathcal{R}(\Omega) (\Omega = \omega \times [-\varepsilon, \varepsilon]) \)

\[
\mathcal{R}(y, \xi) = \mathcal{R}(y) + \xi \mathbf{\hat{a}}_3(y),
\]

(55)

where \(-\varepsilon \leq \xi \leq \varepsilon\).

Therefore, the covariant and contravariant components of the metric tensor on \( \mathcal{R}(\Omega) \) are given by

\[
\begin{bmatrix}
(r + \xi)^2 \sin^2 y_2 & 0 & 0 \\
0 & (r + \xi)^2 & 0 \\
0 & 0 & 1
\end{bmatrix},
\]

(56)

\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}.
\]

The Christoffel symbols on \( \mathcal{R}(\Omega) \) are as follows:

\[
\begin{align*}
\Gamma_{11,2} &= -(r + \xi)^2 \sin y_2 \cos y_2, \\
\Gamma_{11,3} &= -(r + \xi)^2 \sin^2 y_2, \\
\Gamma_{12,1} &= \Gamma_{21,1} = (r + \xi)^2 \sin y_2 \cos y_2, \\
\Gamma_{13,1} &= (\xi - r) \sin^2 y_2, \\
\Gamma_{22,1} &= -(r + \xi), \\
\Gamma_{23,1} &= \xi - r,
\end{align*}
\]

other \( \Gamma_{ij,k} = 0 \),

\[
\begin{align*}
\Gamma^1_{12} &= \Gamma^1_{21} = \cot y_2, \\
\Gamma^1_{13} &= \Gamma^1_{31} = -\frac{1}{r + \xi}, \\
\Gamma^2_{11} &= -\sin y_2 \cos y_2, \\
\Gamma^2_{23} &= \Gamma^2_{32} = -\frac{1}{r + \xi}, \\
\Gamma^3_{11} &= -(r + \xi) \sin^2 y_2, \\
\Gamma^3_{22} &= -(r + \xi),
\end{align*}
\]

other \( \Gamma^k_{ij} = 0 \).

The Riemann tensors on \( \mathcal{R}(\Omega) \) are as follows:

\[
R^p_{ijk} = 0,
\]

\[
R_{ijk} = 0,
\]

(58)

\( i, j, k, p, l = 1, 2, 3. \)

3.2. Semicylindrical Shell. Assume that the middle surface \( S \) of shell is a semicylindrical surface (see Figure 4) whose reference equation is given by the mapping \( \mathcal{R}(\omega) \) defined by

\[
\mathcal{R}(y_1, y_2) = (r \cos y_1, r \sin y_1, y_2),
\]

(59)

where \( r = 1 \) m is a constant, \( 0 \leq y_1 \leq \pi \), and \( 0 \leq y_2 \leq h \) (\( h = 3 \) m). The thickness of the middle surface \( S \) is \( 2\varepsilon \) where \( \varepsilon \) is the semithickness.

Then,

\[
\begin{align*}
\mathbf{\hat{a}}_1 &= \frac{\partial \mathcal{R}}{\partial y_1} = (-r \sin y_1, r \cos y_1, 0), \\
\mathbf{\hat{a}}_2 &= \frac{\partial \mathcal{R}}{\partial y_2} = (0, 0, 1), \\
\partial_1 \mathbf{\hat{a}}_1 &= -(r \cos y_1, -r \sin y_1, 0), \\
\partial_2 \mathbf{\hat{a}}_1 = \partial_2 \mathbf{\hat{a}}_2 &= (0, 0, 0), \\
\partial_1 \mathbf{\hat{a}}_2 &= (0, 0, 0).
\end{align*}
\]

(60)

Therefore, the covariant and contravariant components of the metric tensor on \( S \) are given by

\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & r^2 & 0 \\
0 & 0 & 1
\end{bmatrix},
\]

(61)

\[
\begin{bmatrix}
r^{-2} & 0 \\
0 & 0 \\
0 & 0
\end{bmatrix}.
\]

Then,

\[
\begin{align*}
\mathbf{\hat{a}}_3 &= \frac{\mathbf{\hat{a}}_1 \times \mathbf{\hat{a}}_2}{\mathbf{\hat{a}}_1 \times \mathbf{\hat{a}}_2} = (\cos y_1, \sin y_1, 0), \\
\partial_1 \mathbf{\hat{a}}_3 &= (-\sin y_1, \cos y_1, 0), \\
\partial_2 \mathbf{\hat{a}}_3 &= (0, 0, 0), \\
\partial_1 \mathbf{\hat{a}}_3 &= (-\cos y_1, -\sin y_1, 0),
\end{align*}
\]
\[ \partial_{12} \vec{a}_3 = \partial_{21} \vec{a}_3 = (0,0,0), \]
\[ \partial_{22} \vec{a}_3 = (0,0,0), \]
\[ (b_{\alpha\beta}) = \begin{bmatrix} -r & 0 \\ 0 & 0 \end{bmatrix}, \]
\[ (c_{\alpha\beta}) = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}. \]  

Thus,

\[ a = \det (a_{\alpha\beta}) = r^2, \]
\[ b = \det (b_{\alpha\beta}) = r^2, \]
\[ c = \det (c_{\alpha\beta}) = 1. \]  

The Christoffel symbols on \( S \) are

\[ \Gamma_{\alpha\beta\gamma}^\alpha = 0, \]
\[ \Gamma_{\rho\sigma}^\alpha = 0. \]  

The Riemann tensors on \( S \) are as follows:

\[ R_{\alpha\beta\gamma\delta}^\sigma = 0, \]
\[ R_{\alpha\beta\gamma\delta}^\alpha = 0, \]  

\( \alpha, \beta, \sigma, \gamma, \lambda = 1,2. \)

Hence, for each \( \epsilon > 0 \), the reference configuration of the shell with middle surface \( S = \Theta(\vec{\sigma}) \) is \( \Theta(\Pi) (\Pi = \vec{\sigma} \times [-\epsilon, \epsilon]) \)

\[ \Theta (y, \xi) = \Theta (y) + \xi \vec{a}_3 (y), \]  

where \( -\epsilon \leq \xi \leq \epsilon \).

So, the covariant and contravariant components of the metric tensor on \( \Theta(\Pi) \) are given by

\[ (g_{ij}) = \begin{bmatrix} (r + \xi)^2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \]
\[ (g^{ij}) = \begin{bmatrix} 1 & 0 & 0 \\ (r + \xi)^2 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \]  

The Christoffel symbols on \( \Theta(\Pi) \) are as follows:

\[ \Gamma_{113} = -(r + \xi), \]
\[ \Gamma_{131} = (r + \xi), \]
\[ \text{other } \Gamma_{ijk} = 0, \]
\[ \Gamma^1_{13} = \Gamma^1_{31} = \frac{1}{r + \xi}, \]
\[ \Gamma^3_{11} = -(r + \xi), \]
\[ \text{other } \Gamma^k_{ij} = 0. \]  

The Riemann tensors on \( \Theta(\Pi) \) are as follows:

\[ R_{\alpha\beta\gamma\delta}^\rho = 0, \]
\[ R_{\alpha\beta\gamma\delta}^\alpha = 0, \]  

\( i, j, k, p, l = 1,2,3. \)
