In this paper, we propose a numerical method for solving the time fractional Richards’ equation. We first approximate the time fractional derivative of the mentioned equations by a scheme of order $O(\tau^{2-\alpha})$, $0 < \alpha < 1$; then, we use the finite point method to approximate the spatial derivatives. Before the discrete spatial derivatives, we introduced the basic principles of the finite point method. We solve the one- and two-dimensional versions of these equations using the proposed method. Moreover, the stability properties of the discretized scheme related to time are theoretically analyzed. Numerical results showed the efficiency of the method presented in this paper.

1. Introduction

In recent years, the theory of fractional calculus and fractional differential equation has been widely used in many fields, such as mechanics, physics, biomathematics, engineering, automatic control, fractal, and so on. Richards’ equation is a basic model for describing soil water movement. The multiscale heterogeneity of soil makes the nature of water diffusion process not consistent with the preconditions of applying Fick’s law, which often reflects the abnormal diffusion phenomenon of soil water infiltration. In response to the above phenomenon, the fractional Richards’ equation is proposed to describe the process of water movement in unsaturated soil [1, 2]. After years of research and practice, numerical simulation has become an effective technical means to simulate soil water flow and infiltration [3–5]. Pachepsky et al. [1] used the finite difference method to solve the time fractional Richard’s equation. Chen et al. [6] used the finite difference method and Kansa method to discretize the time fractional derivatives and the space fractional derivatives, respectively, in solving the time fractional diffusion equation. Freitas et al. [7] proposed the modified fractional integral Richard’s equation to predict the anomalous diffusion process of horizontal infiltration in unsaturated media.

Meshless methods have become very popular in physics and engineering for solving partial differential equations because they do not require mesh reorganization in solving large deformation and many discontinuous problems [8–10]. Meanwhile, a meshless method is not restricted by grid, and its basic idea is to arrange nodes according to certain rules in the solution domain, use shape function to represent unknown field variables in the local region, and finally form stiffness matrix equations to solve it [11]. Onate et al. [12, 13] proposed the finite point method, which first added the stability term to the equation, and then constructed the shape function by moving least squares and discretized the partial differential equation with the stability term by collocation method. Tiwari and Kuhnert [14] developed a finite pointset method, which uses Taylor expansion and weighted least squares to approximate spatial derivatives and uses collocation schemes to discretize equations. Shojaei et al. [15] used the meshless finite point method to solve elastodynamic problems through an explicit velocity. In the same year, Kamranian et al. [16] discussed
the two-dimensional initial boundary value problem associated with the sine-Gordon equation using the finite point method. Li and Qin [17] used the meshless finite point method to solve the time fractional convection-diffusion equations, and the numerical results show that this method has higher computational accuracy than the finite difference method. Previously, their work [17] used the finite point method to solve the time fractional linear convection-diffusion equations and obtained better results. Currently, the finite point method is used to solve the time fractional nonlinear soil water movement equation, which belongs to the convection-diffusion equation. The finite point method first applies a stability term to the governing equation and then uses the meshless collocation method to discretize the governing equation. The numerical results show that the calculation accuracy is better when the stability term is applied; that is, applying a stability term can reduce the calculation error and make the simulation result more accurate.

In this paper, we consider the time fractional Richards’ equation as the following: for one-dimensional,

\[ \frac{C}{\partial t} \mathcal{D}^{\alpha}_{t} \theta = \frac{\partial}{\partial z} \left( D(\theta) \frac{\partial \theta}{\partial z} \right) + \frac{\partial K(\theta)}{\partial z} + f, \quad z \in \Omega_1, \quad t > 0, \]  

subject to the following general initial and boundary conditions:

\[ \theta(z, 0) = \theta_0(z), \quad z \in \Omega_1, \]

\[ \theta(z, t) = \varphi(z, t), \quad z \in \partial \Omega_1, \quad t > 0, \tag{2} \]

and for two-dimensional,

\[ \frac{C}{\partial t} \mathcal{D}^{\alpha}_{t} \theta = \frac{\partial}{\partial x} \left( D(\theta) \frac{\partial \theta}{\partial x} \right) + \frac{\partial}{\partial z} \left( D(\theta) \frac{\partial \theta}{\partial z} \right) + \frac{\partial K(\theta)}{\partial z} + f, \quad z \in \Omega_1, \quad t > 0, \tag{3} \]

subject to the following general initial and boundary conditions:

\[ \theta(x, z, 0) = \theta_0(x, z), \quad z \in \Omega_2, \]

\[ \theta(x, z, t) = \psi(x, z, t), \quad z \in \partial \Omega_2, \quad t > 0, \tag{4} \]

where \( \Omega_1 = [0, L], \) \( \Omega_2 = [0, L] \times [0, L], \) \( \theta \) is soil water content, \( D(\theta) \) is diffusivity, and \( K(\theta) \) is water conductivity. Assume that the nonlinear term \( D(\theta) \) satisfies \( 0 < m \leq D(\theta) \leq M \) for positive \( m, M. \) \( K(\theta) \) satisfies \( |K(\theta)| \leq |L|\theta \) and \( |K'(\theta)| \leq L, \) where \( L \) is the different positive constant.

In equations (1) and (3), \( \mathcal{D}^{\alpha}_{t} \) is the Caputo fractional derivative of order \( \alpha \) (\( 0 < \alpha < 1 \)), which is defined as

\[ \mathcal{D}^{\alpha}_{t} \theta(t) = \frac{1}{\Gamma(1-\alpha)} \int_{0}^{t} \frac{\partial^{\alpha} \theta(s)}{\partial (t-s)^{\alpha}} ds. \tag{5} \]

Equations (1) and (3) belong to the part of soil water and salt transport model. Aiming at the convection and dispersion phenomenon in the soil water and salt transport model, the finite element method (FEM) and finite difference method (FDM) are easy to produce numerical oscillation when convection is dominant. Numerical methods such as characteristic finite element and characteristic finite difference can eliminate numerical oscillation to a certain extent, but these numerical methods need to rely on the grid in the calculation process, which increases the calculation amount. The meshless method defines the shape function at the nodes in the local domain, which overcomes the dependence on the grid in numerical calculation. Meanwhile, by adding nodes in the computational domain, the computational accuracy in the local region can be improved. The finite point method uses the moving least squares (MLS) method to construct the shape function and the collocation method to discretize the governing equation, which belongs to the meshless method. For equations (1) and (3), the time fractional Caputo derivatives were approximated by \( L1 \) interpolation, and the space derivatives were discretized by finite point method.

The paper is organized as follows: The finite point method is introduced in Section 2. The scheme of discrete time fractional soil water movement equations is deduced in Section 3. In Section 4, the stability of the time discretization of the one-dimensional and two-dimensional time fractional soil water movement equations is analyzed. In Section 5, some numerical examples are provided to show the accuracy of the proposed method. Finally, a conclusion is drawn in Section 6.

2. Finite Point Method

The finite point method (FPM) uses the moving least squares (MLS) method to construct the shape function and the collocation method to discretize the governing equations. In order to reduce the error and avoid the numerical oscillation, the stability term is added to the discrete equation [12, 13].

2.1. Moving Least Squares (MLS) Approximation. In \( (0, L) \), the unknown function \( u(x) \) can be approximated in the neighborhood \( \Omega_{x} \) of the point \( x \):

\[ u(x) \approx u_{h}(x) = \sum_{i=1}^{N} \varphi_{i}(x)u_{i} = \Phi(x)U, \quad x \in \Omega_{x}, \tag{6} \]

\[ U = (u_{1}, u_{2}, \ldots, u_{N})^{T}, \]

where \( \Phi(x) \) is the vector of MLS shape functions corresponding to \( N \) nodes in the support domain of the point \( x \) and can be expressed by

\[ \Phi(x) = p^{T}(x)A^{-1}(x)B(x), \tag{7} \]

where \( p^{T}(x) = (p_{1}(x), p_{2}(x), \ldots, p_{m}(x)) \) is a complete monomials basis of order \( m. \) \( A(x) \) and \( B(x) \) are defined by

\[ A(x) = \sum_{i=1}^{N} W_{i}(x)p(x_{i})p^{T}(x_{i}), \]

\[ B(x) = [W_{1}(x)p(x_{1})W_{1}(x)p(x_{1}), \ldots, W_{N}(x)p(x_{N})]. \tag{8} \]

Let \( y = A^{-1}p, \) then shape function is \( \Phi^{T} = y^{T}B. \) The partial derivatives of the shape functions are, respectively,
From the expression of the shape functions, we can see that the smoothness of the shape function is determined by \( \phi \), then the stability term is

\[
\phi = \frac{e^{-r^2} - e^{-\beta^2}}{1 - e^{-\beta^2}}, \quad r \leq 1, \\
0, \quad r > 1,
\]

where \( \beta \) is the shape parameter of the Gaussian function and \( r \) is the relative distance:

\[
r = \frac{d_i}{d_{mi}} = \frac{|x - x_i|}{d_{mi}}.
\]

where \( d_i \) is the distance between the calculation point \( x \) and the node \( x_i \), and \( d_{mi} \) is the support domain size of weight function. The support domain size \( d_{mi} \) of node \( x_i \) is usually determined by \( d_{mi} = \text{scale} \cdot d_i \), where scale is the impact factor and \( d_i \) is used to control the size of the support domain. \( d_i = \sqrt{(x - x_i)^2 + (y - y_i)^2} \) in the two-dimensional case.

2.2. Adding Stability Term. The one-dimensional time fractional soil water movement equation is shown in equation (1). Let

\[
r = \frac{\partial K(\theta)}{\partial \theta} \cdot \frac{\partial \theta}{\partial z} + D(\theta) \cdot \frac{\partial^2 \theta}{\partial z^2} + \frac{\partial D(\theta)}{\partial \theta} \cdot \left( \frac{\partial \theta}{\partial z} \right)^2 + f.
\]

(12)

Using Taylor’s expansion and flow balance principles, the stability term is

\[
R = \frac{h}{2} \cdot \frac{\partial r}{\partial z} = 0.
\]

(13)

where \( h \) is the characteristic length ([12, 13]).

After adding the stability term, equation (1) can be converted into the following form:

\[
C_0 D_t^\alpha \theta - r + \frac{h}{2|u|} \cdot u \cdot \nabla r = 0,
\]

(14)

Similarly, equation (3) can be converted into the following form:

\[
C_0 D_t^\alpha \theta - r + \frac{h}{2|u|} \cdot u \cdot \nabla r = 0,
\]

(15)

where

\[
\begin{align*}
\frac{\partial K(\theta)}{\partial \theta} \cdot \frac{\partial \theta}{\partial z} + D(\theta) \cdot \frac{\partial^2 \theta}{\partial z^2} + \frac{\partial D(\theta)}{\partial \theta} \left( \frac{\partial \theta}{\partial z} \right)^2 + f - \frac{\partial K(\theta)}{\partial \theta} \cdot \frac{\partial \theta}{\partial z}, \\
+ D(\theta) \cdot \frac{\partial^2 \theta}{\partial z^2} + f - \frac{\partial K(\theta)}{\partial \theta} \cdot \frac{\partial \theta}{\partial z},
\end{align*}
\]

(16)

\[
\nabla r = \left[ \frac{\partial r}{\partial x}, \frac{\partial r}{\partial z} \right]^T,
\]

(17)

the coefficient of convection term \( u = [-\partial K(\theta)/\partial \theta], -(\partial K(\theta)/\partial \theta)] \), and \( h \) is the characteristic length.

2.3. Collocation Method. Assume that the equation is as follows:

\[
L[u(x)] = f(x), \quad x \in \Omega.
\]

(18)

The Dirichlet boundary condition is

\[
u - u_p = 0, \quad x \in \Gamma_u.
\]

(19)

The Neumann boundary condition is

\[
B(u) = g(x), \quad x \in \Gamma_n.
\]

(20)

where \( L \) and \( B \) are the differential operators, \( u \) is the unknown function, \( u_p \) is the prescribed value of \( u \) in \( \Gamma_u \), the boundary \( \partial \Omega = \Gamma_1 \cup \Gamma_u \), and \( \Gamma_1 \cap \Gamma_u = 0 \) in \( \Omega \).

Assume the approximate expression of \( u \) is \( \tilde{u} \); then, the approximate function will inevitably produce residuals in the domain and on the boundary, respectively. By using the weighted residual method, equations (18)–(20) are replaced by the following formula:

\[
\begin{align*}
\int_{\Omega} W_1[L(\tilde{u}) - f(x)]d\Omega + \int_{\Gamma_n} W_2[B(\tilde{u}) - g(x)]d\Gamma + \int_{\Gamma_1} W_3[\tilde{u} - u_p]d\Gamma,
\end{align*}
\]

(21)

where \( W_1, W_2, \) and \( W_3 \) have different definitions. Let \( W_1 = W_2 = W_3 = \delta_i \), where \( \delta_i \) is the Dirac \( \delta \) function, from which the point equation can be obtained as

\[
L[\tilde{u}(x_i)] - f(x_i) = 0, \quad x_i \in \Omega, \quad i = 1, \ldots, n_d,
\]

(22)

\[
u(x_i) - u_p = 0, \quad x_i \in \Gamma_u, \quad i = n_d + n_t + 1, \ldots, n_d + n_t + n_u,
\]

(23)

\[
B(\tilde{u}(x_i)) - g(x_i) = 0, \quad x_i \in \Gamma_n, \quad i = n_d + 1, \ldots, n_d + n_t + n_u.
\]

(24)

where \( n_d \) is the number of nodes on the Dirichlet boundary, \( n_t \) is the number of nodes on the Neumann boundary, \( n_u \) is the number of nodes which satisfy \( n_d = N - n_r - n_u \) in \( \Omega \).
system of equations (22)–(24) leads to a system of algebraic
equations of the form
\[ K \mu_p = F. \]  
(25)

If the differential operators L and B are nonlinear, it is a
nonlinear system of equations, and the approximate value of
nodes should be solved by the iterative method [18–21].
Monotone iterative ADI (alternating direction implicit) was
used for solving coupled systems of nonlinear parabolic
equations, and Boglae [19] stopped the algorithm and the
number of iterations by verifying the convergence order.
The inexact Hermitian/Skew-Hermitian Splitting (IHSS) was
presented for solving system of nonlinear equations [20].
The stopped criterion for the outer iterations in INHSS
algorithm were \(\|F(u^k)\|/\|F(u^0)\| \leq \delta\), where \(\delta\) is a prescribed
accuracy. A novel biperametric six-order iterative scheme
for solving nonlinear systems was presented by Bahl et al.
[21]. The number of iterations needed to converge to the
solution such that the stopping criterion \(\|x^{(k+1)} - x^{(k)}\| +
\|F(x^{(k)})\| < 10^\delta\) was satisfied [21].

3. Algorithm Construction of Time Fractional
Soil Water Movement Equation

3.1. In the One-Dimensional Case

3.1.1. Time Discretization. Let \( t_m = m \Delta t, m = 1, 2, \ldots, n, \)
where \( \Delta t = T/n \) is time step. The time fractional derivative at
\( t = t_m \) can be approximated by the following scheme:
\[
\frac{\partial}{\partial t} \frac{D_t^\alpha \theta(t)}{D_t^\alpha} |_{t=t_m} = \frac{1}{(1 - \alpha)} \sum_{k=1}^{m} \frac{\theta(t_k) - \theta(t_{k-1})}{\Delta t}
\]
\[
+ \frac{1}{(1 - \alpha)} \sum_{k=1}^{m} \left[ a_{m-k+1}^{(a)} \theta(t_{m-k+1}) - a_{m-k}^{(a)} \theta(t_k) \right]
\]
\[
- a_{m-1}^{(a)} \theta(t_0) + R_m,
\]
where
\[
\begin{align*}
 a_{m-k+1}^{(a)} &= (m - k)^{1-\alpha} - (m - k - 1)^{1-\alpha}, \\
 a_{m-k}^{(a)} &= (m - k + 1)^{1-\alpha} - (m - k)^{1-\alpha},
\end{align*}
\]
and the truncation error is
\[
| R_m | \leq C (\Delta t)^{2-\alpha}.
\]
(26)

So, the L1 approximation of Caputo derivative is
\[
\frac{\partial}{\partial t} \frac{D_t^\alpha \theta(t)}{D_t^\alpha} |_{t=t_m} \approx \frac{\tau^{-\alpha}}{(2 - \alpha)} \left[ a_0^{(a)} \theta(t_m) - \sum_{k=1}^{m-1} (a_{m-k}^{(a)} - a_{m-k-1}^{(a)}) \theta(t_k) \right]
\]
\[
- a_{m-1}^{(a)} \theta(t_0) \right].
\]
(29)

Let \( \theta^m = \theta^m(x) \) be the numerical approximation to \( \theta(x, t_m) \) and \( f^m = f(x, t_m) \); then, equation (1) can be
discretized as the following scheme:
\[
\frac{\tau^{-\alpha}}{2} \left[ a_0^{(a)} \theta^m - \sum_{k=1}^{m-1} (a_{m-k}^{(a)} - a_{m-k-1}^{(a)}) \theta^k - a_{m-1}^{(a)} \theta \right]
\]
\[
= \frac{\partial}{\partial z} \left( D(\theta^m) \frac{\partial \theta^m}{\partial z} \right) + \frac{\partial K(\theta^m)}{\partial z} + f^m.
\]
(30)

3.1.2. Spatial Discretization. Equation (1) can be trans-
formed into
\[
\frac{\partial}{\partial t} \frac{D_t^\alpha \theta}{D_t^\alpha} - \frac{\partial K(\theta)}{\partial \theta} \frac{\partial \theta}{\partial z} + D(\theta) \frac{\partial^2 \theta}{\partial z^2} + \frac{\partial D(\theta)}{\partial \theta} \frac{\partial \theta}{\partial z} \right) + f = 0.
\]
(31)

After adding the stability term to equation (31), we can obtain
\[
\frac{\partial}{\partial t} \frac{D_t^\alpha \theta}{D_t^\alpha} - \frac{\partial K(\theta)}{\partial \theta} \frac{\partial \theta}{\partial z} + D(\theta) \frac{\partial^2 \theta}{\partial z^2} + \frac{\partial D(\theta)}{\partial \theta} \frac{\partial \theta}{\partial z} + \frac{\partial D(\theta)}{\partial \theta} \frac{\partial \theta}{\partial z} + \frac{\partial D(\theta)}{\partial \theta} \frac{\partial \theta}{\partial z} + \frac{\partial f}{\partial \theta}
\]
\[
= 0.
\]
(32)

The \( N \) nodes \( z = z_i (i = 1, 2, \ldots, N) \) in the domain \( (a, b) \)
are used for the distribution, and the approximate function at
the node \( z_p \) is
\[
\theta(z_p) \approx \bar{\theta}(z_p) = \sum_{i=1}^{N} \phi_i(z_p) \theta(z_i),
\]
(33)

where \( \phi_i \) represents the shape function formed by \( z_p \) as
the support domain center and the point \( z_o \) and \( N \) is the number
of nodes in the local support domain with \( z_p \) as the support
domain center.

From equation (33), the first derivative, the second derivative,
and the third derivative of the approximation function at the node \( z_p \) can be expressed as
\[
\begin{aligned}
\left. \frac{\partial \theta(z)}{\partial z} \right|_{z=z_p} &= \sum_{i=1}^{N} \frac{\partial \phi_i(z)}{\partial z} \theta(z_i), \\
\left. \frac{\partial^2 \theta(z)}{\partial z^2} \right|_{z=z_p} &= \sum_{i=1}^{N} \frac{\partial^2 \phi_i(z)}{\partial z^2} \theta(z_i),
\end{aligned}
\]
\[
\left. \frac{\partial^3 \theta(z)}{\partial z^3} \right|_{z=z_p} = \sum_{i=1}^{N} \frac{\partial^3 \phi_i(z)}{\partial z^3} \theta(z_i).
\]
(34)
Substituting equations (33) and (34) in equation (32), we can obtain the spatial discrete equation. Let \( \theta_i^m \) be the numerical approximation to \( \theta(z, t_m) \), from equations (29) and (33)–(35), the fully discrete scheme of equation (1) at \( \theta(z, t_m) \) is

\[
\frac{r^{-\alpha}}{\Gamma(2 - \alpha)} \left[ a_0^{(a)} \theta^m_p - \sum_{k=1}^{m-1} \left( a_{m-k-1}^{(a)} - a_{m-k}^{(a)} \right) \theta^m_p - a_{m-1}^{(a)} \theta^m_p \right] \\
= \sum_{i=1}^{N} a_{pi} \cdot \theta^m_i + \frac{h}{2} \frac{\partial D(\theta^m)}{\partial \theta} \left( \sum_{i=1}^{N} \frac{\partial^2 \phi_{pi}}{\partial z^2} \cdot \theta^m_i \right)^2 \\
- \frac{3h}{2} \frac{\partial D(\theta^m)}{\partial \theta} \left( \sum_{i=1}^{N} \frac{\partial^2 \phi_{pi}}{\partial z^2} \cdot \theta^m_i \right) \\
\cdot \frac{h}{2} \frac{\partial^2 \phi_{pi}}{\partial z^2} \left( \sum_{i=1}^{N} \frac{\partial^2 \phi_{pi}}{\partial z^2} \cdot \theta^m_i \right)^3 \\
+ \frac{h}{2} \frac{\partial f^m}{\partial z} \bigg|_{z=z_p} + f^m \right],
\]

where

\[
a_{pi} = \left( \frac{\partial K(\theta^m)}{\partial \theta} \frac{\partial \phi_{pi}}{\partial z} \right)_{z=z_p} + \left( D(\theta^m) \frac{\partial K(\theta^m)}{\partial \theta} \right) \frac{\partial^2 \phi_{pi}}{\partial z^2} \bigg|_{z=z_p},
\]

\]

Let \( \theta^m = (\theta_1^m, \theta_2^m, \ldots, \theta_p^m, \ldots, \theta_N^m)^T, \quad m = 1, 2, 3, \ldots \)

Equation (35) is as follows:

\[
p^m \theta^m = \frac{r^{-\alpha}}{\Gamma(2 - \alpha)} \sum_{k=1}^{m-1} \left( a_{m-k-1}^{(a)} - a_{m-k}^{(a)} \right) \theta^k \\
+ \frac{r^{-\alpha}}{\Gamma(2 - \alpha)} a_{m-1}^{(a)} \theta^m + F^m, \tag{38}
\]

where

\[
p^m = \left( \frac{r^{-\alpha}}{\Gamma(2 - \alpha)} a_0^{(a)}, E - A - \frac{\partial D(\theta^m)}{\partial \theta} \frac{\partial^2 \phi_{pi}}{\partial z^2} \theta^m \right) \\
+ \frac{3h}{2} \frac{\partial D(\theta^m)}{\partial \theta} \left( \sum_{i=1}^{N} \frac{\partial^2 \phi_{pi}}{\partial z^2} \theta^m_i \right)^2 \\
\cdot C + \frac{h}{2} \frac{\partial^2 D(\theta^m)}{\partial \theta^2} \left( \sum_{i=1}^{N} \frac{\partial^2 \phi_{pi}}{\partial z^2} \theta^m_i \right)^2 \cdot B,
\]

\[
A = \begin{bmatrix} a_{11} & a_{12} & \ldots & a_{1N} \\ a_{21} & a_{22} & \ldots & a_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ a_{p1} & a_{p2} & \ldots & a_{pN} \\ a_{N1} & a_{N2} & \ldots & a_{NN} \end{bmatrix},
\]

\[
B = \begin{bmatrix} \frac{\partial \phi_{11}}{\partial z} & \frac{\partial \phi_{12}}{\partial z} & \ldots & \frac{\partial \phi_{1N}}{\partial z} \\ \frac{\partial \phi_{21}}{\partial z} & \frac{\partial \phi_{22}}{\partial z} & \ldots & \frac{\partial \phi_{2N}}{\partial z} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial \phi_{p1}}{\partial z} & \frac{\partial \phi_{p2}}{\partial z} & \ldots & \frac{\partial \phi_{pN}}{\partial z} \\ \frac{\partial \phi_{N1}}{\partial z} & \frac{\partial \phi_{N2}}{\partial z} & \ldots & \frac{\partial \phi_{NN}}{\partial z} \end{bmatrix},
\]

\[
C = \begin{bmatrix} \frac{\partial^2 \phi_{11}}{\partial z^2} & \frac{\partial^2 \phi_{12}}{\partial z^2} & \ldots & \frac{\partial^2 \phi_{1N}}{\partial z^2} \\ \frac{\partial^2 \phi_{21}}{\partial z^2} & \frac{\partial^2 \phi_{22}}{\partial z^2} & \ldots & \frac{\partial^2 \phi_{2N}}{\partial z^2} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 \phi_{p1}}{\partial z^2} & \frac{\partial^2 \phi_{p2}}{\partial z^2} & \ldots & \frac{\partial^2 \phi_{pN}}{\partial z^2} \\ \frac{\partial^2 \phi_{N1}}{\partial z^2} & \frac{\partial^2 \phi_{N2}}{\partial z^2} & \ldots & \frac{\partial^2 \phi_{NN}}{\partial z^2} \end{bmatrix},
\]

\[
F = \begin{bmatrix} \frac{h}{2} \frac{\partial f^m}{\partial z} \bigg|_{z=z_1} + f_1^m \\ \vdots \\ \frac{h}{2} \frac{\partial f^m}{\partial z} \bigg|_{z=z_p} + f_p^m \\ \vdots \\ \frac{h}{2} \frac{\partial f^m}{\partial z} \bigg|_{z=z_N} + f_N^m \end{bmatrix}.
\]

3.2. In the Two-Dimensional Case

3.2.1. Time Discretization. Let \( t_m = m \Delta t, m = 1, 2, \ldots, n \), where \( \Delta t = T/n \) is the time step, the approximation of the time fractional derivative at \( t = t_m \) is shown in equation (29). Let \( \theta^m = \theta^m(x, z) \) be the numerical approximation to \( \theta(x, z, t_m) \) and \( f^m = f(x, z, t_m) \); then, equation (3) can be discretized as the following scheme:
\[
\tau^{-\alpha} \left[ \Phi^{(a)}_{m-k} - \sum_{k=1}^{m-1} (\Phi^{(a)}_{m-k} - \Phi^{(a)}_{m-k-1}) \theta^k - \Phi^{(a)}_{m-1} \theta^0 \right] \\
= \frac{\partial}{\partial x} \left( D(\theta) \frac{\partial \theta}{\partial x} \right) + \frac{\partial}{\partial z} \left( D(\theta) \frac{\partial \theta}{\partial z} \right) + \frac{\partial}{\partial z} \left( D(\theta) \frac{\partial \theta}{\partial x} \right) + \frac{\partial}{\partial z} \left( D(\theta) \frac{\partial \theta}{\partial z} \right) + f. 
\]

(40)

3.2.2. Spatial Discretization. The governing equation (3) can be rewritten as

\[
\sum_{i,j} D_{ij}^{\theta} \theta - r + \frac{h}{2|u|} \cdot \nabla r = 0,
\]

(41)

where \( r, \nabla r, u \) are shown in Section 2.2. Then, equation (3) can be converted into

\[
\sum_{i,j} D_{ij}^{\theta} \theta - r + \frac{h}{2|u|} \cdot \nabla r = 0,
\]

(42)

The approximate function at \( \theta(x_p, z_q) \) is

\[
\theta(x_p, z_q) = \sum \phi_{p,q}(x_p, z_q) \cdot \theta(x_i, z_j),
\]

(44)

where \( \phi_{p,q} \) represents the shape function formed by \( \theta(x_p, z_q) \) as the center of the support domain and \( \theta(x_i, z_j) \).

The approximate expressions of the unknown function, the first derivative, the second derivative, and the third derivative of the unknown function at \( \theta(x_p, z_q) \) can be obtained by constructing the shape function. So, the full discrete scheme of equation (3) at \( \theta(x_p, z_q, t_m) \) is as follows:
\[
\frac{r^{-\alpha}}{\Gamma(2-\alpha)} \left[ a_0^{(a)} \vartheta_{pq}^{n} - \sum_{k=1}^{m-1} (a_{m-k}^{(a)} - a_{m-k-1}^{(a)}) \vartheta_{pq}^{n-1} - a_{m-k}^{(a)} \vartheta_{pq}^{n} \right] = \sum_{ij} \left[ \frac{\partial K}{\partial \theta} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \vartheta} + D(\vartheta_{pq}^{n}) \right] + D(\vartheta_{pq}^{n}) \frac{\partial^2 \varphi_{pq,ij}^{n}}{\partial \theta^2} + \frac{h}{2|u|} \frac{\partial K}{\partial \theta} \cdot D(\vartheta_{pq}^{n}) + \frac{h}{2|u|} \frac{\partial^3 \varphi_{pq,ij}^{n}}{\partial \vartheta^3} + \frac{h}{2|u|} \frac{\partial^4 \varphi_{pq,ij}^{n}}{\partial \vartheta^4} + \frac{h}{2|u|} \frac{\partial^5 \varphi_{pq,ij}^{n}}{\partial \vartheta^5} + \frac{h}{2|u|} \frac{\partial^6 \varphi_{pq,ij}^{n}}{\partial \vartheta^6} \left( \Phi \right)_{x=x_{p}, z=z_{q}}.
\]

\[
\frac{h}{2|u|} \frac{\partial K}{\partial \theta} \left[ \frac{\partial D(\vartheta_{pq}^{n})}{\partial \theta} \left( \sum_{ij} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \vartheta} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \xi} \right) \left( \sum_{ij} \frac{\partial^2 \varphi_{pq,ij}^{n}}{\partial \vartheta^2} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \xi} \right) + \frac{\partial^2 D(\vartheta_{pq}^{n})}{\partial \theta^2} \left( \sum_{ij} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \theta} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \xi} \right) \right]^{3}
\]

\[
\frac{\partial D(\vartheta_{pq}^{n})}{\partial \theta} \left( \sum_{ij} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \vartheta} \right) \left( \sum_{ij} \frac{\partial^2 \varphi_{pq,ij}^{n}}{\partial \vartheta^2} \right) \left( \sum_{ij} \frac{\partial^3 \varphi_{pq,ij}^{n}}{\partial \vartheta^3} \right) \left( \sum_{ij} \frac{\partial^4 \varphi_{pq,ij}^{n}}{\partial \vartheta^4} \right) \left( \sum_{ij} \frac{\partial^5 \varphi_{pq,ij}^{n}}{\partial \vartheta^5} \right) \left( \sum_{ij} \frac{\partial^6 \varphi_{pq,ij}^{n}}{\partial \vartheta^6} \right)
\]

\[
\frac{\partial D(\vartheta_{pq}^{n})}{\partial \theta} \left( \sum_{ij} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \vartheta} \right) \left( \sum_{ij} \frac{\partial^2 \varphi_{pq,ij}^{n}}{\partial \vartheta^2} \right) \left( \sum_{ij} \frac{\partial^3 \varphi_{pq,ij}^{n}}{\partial \vartheta^3} \right) \left( \sum_{ij} \frac{\partial^4 \varphi_{pq,ij}^{n}}{\partial \vartheta^4} \right) \left( \sum_{ij} \frac{\partial^5 \varphi_{pq,ij}^{n}}{\partial \vartheta^5} \right) \left( \sum_{ij} \frac{\partial^6 \varphi_{pq,ij}^{n}}{\partial \vartheta^6} \right)
\]

\[
\frac{\partial \varphi_{pq,ij}^{n}}{\partial \theta} \left( \sum_{ij} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \vartheta} \right) \left( \sum_{ij} \frac{\partial^2 \varphi_{pq,ij}^{n}}{\partial \vartheta^2} \right) \left( \sum_{ij} \frac{\partial^3 \varphi_{pq,ij}^{n}}{\partial \vartheta^3} \right) \left( \sum_{ij} \frac{\partial^4 \varphi_{pq,ij}^{n}}{\partial \vartheta^4} \right) \left( \sum_{ij} \frac{\partial^5 \varphi_{pq,ij}^{n}}{\partial \vartheta^5} \right) \left( \sum_{ij} \frac{\partial^6 \varphi_{pq,ij}^{n}}{\partial \vartheta^6} \right)
\]

\[
\frac{\partial \varphi_{pq,ij}^{n}}{\partial \theta} \left( \sum_{ij} \frac{\partial \varphi_{pq,ij}^{n}}{\partial \vartheta} \right) \left( \sum_{ij} \frac{\partial^2 \varphi_{pq,ij}^{n}}{\partial \vartheta^2} \right) \left( \sum_{ij} \frac{\partial^3 \varphi_{pq,ij}^{n}}{\partial \vartheta^3} \right) \left( \sum_{ij} \frac{\partial^4 \varphi_{pq,ij}^{n}}{\partial \vartheta^4} \right) \left( \sum_{ij} \frac{\partial^5 \varphi_{pq,ij}^{n}}{\partial \vartheta^5} \right) \left( \sum_{ij} \frac{\partial^6 \varphi_{pq,ij}^{n}}{\partial \vartheta^6} \right)
\]

4. Stability

In order to analyze the stability of one-dimensional and two-dimensional time fractional soil-water movement equations, we firstly define the functional spaces endowed with standard norms and inner products:

\[
H^1(\Omega) = \{ v \in L^2(\Omega), \forall v \in L^2(\Omega) \},
\]

\[
H^1_0(\Omega) = \{ v \in H^1(\Omega), v|_{\partial \Omega} = 0 \},
\]

where \( L^2(\Omega) \) is the space of measurable functions whose square is Lebesgue integrable in \( \Omega \) and the inner product form of \( L^2(\Omega) \) is

\[
(u, v) = \int_{\Omega} u(x)v(x)dx,
\]

\[
(u, v) = \int_{\Omega} u(x)v(x)dx dy,
\]

and the norm in \( L^2(\Omega) \) is
\[ \|\theta\| = (\theta, \theta)^{1/2} = \left( \int_\Omega \theta^2 \, dx \right)^{1/2}, \]
\[ \|\theta\| = (\theta, \theta)^{1/2} = \left( \int_\Omega \theta^2 \, dx \, dy \right)^{1/2}. \] (48)

**Lemma 1** (see [22]). Let \( \alpha \in (0, 1) \), \( a_{i}^{(\alpha)} = (l + 1)^{-\alpha} - l^{-\alpha}, \) \( l = 0, 1, 2, \ldots, \) then
\[ (1) \ 1 = a_{0}^{(\alpha)} > a_{1}^{(\alpha)} > \cdots > a_{t}^{(\alpha)} > 0; \ a_{t}^{(\alpha)} \to 0, \] \[ \quad \text{when } l \to \infty; \]
\[ (2) \ (1 - \alpha)l^{-\alpha} < a_{l-1}^{(\alpha)} < (1 - \alpha)(l - 1)^{-\alpha}, \ l \geq 1. \]

Lemma 1 gives the magnitude relationship of the coefficients in the time-discrete format.

**Lemma 2** (see [23]). Let \( \{T_h\}, 0 < h \leq 1 \), denote a quasiquasiuniform family of subdivisions of a polyhedral domain \( \Omega \subset \mathbb{R}^d \). Let \( (K, P, N) \) be a reference finite element space such that \( P \subset W^{l,p}(K) \cap \cap W^{m,q}(K) \) is a finite-dimensional space of functions on \( K \), \( N \) is a basis for \( P \), and \( \lambda \) is a sufficiently large constant. Then, \( \exists \) a constant \( C \) independent of \( h \) satisfying
\[ \left( \sum_{e \in T_h} \| v \|_{W^{l,p}(K)} \right)^{1/p} \leq C h^{n-1} \min (0, (d/p) - (d/q)) \left( \sum_{e \in T_h} \| v \|_{W^{l,p}(K)} \right)^{1/q}, \] (49)
for all \( v \in V_h \).

**Lemma 3** (see [24]). Let \( \Omega \) be a given region with boundary \( \partial \Omega \), \( T_h \) be a uniform partition on \( \Omega \), \( h \) is the size of unit \( e \) in \( T_h \) and the finite element space \( V_h = \{ v : v \mid e \in P_k(e), \forall e \in T_h \} \), suppose \( \exists \) a constant \( C \) independent of \( h \) satisfying
\[ \| u_h \|_{l,p,0} \leq C h^{k-n+l/(p-1)} \| u_h \|_{l,0}. \] (50)
where \( l \leq k, \ q \leq p, \) and \( n \) is the dimension.

Lemmas 2 and 3 refer to the inverse inequality of finite element, but their forms are different. In the discussion of stability, we use the classical finite element inverse estimation inequality; that is, let \( \Omega \) be a given region with boundary \( \partial \Omega \), \( T_h \) be a uniform partition on \( \Omega \), \( h \) is the size of unit \( e \) in \( T_h \), and the finite element space \( V_h = \{ v : v \mid e \in P_k(e), \forall e \in T_h \} \) on \( T_h \), where \( P_k(e) \) is a polynomial space whose number of times does not exceed \( k \); then for the function \( u_h \in V_h \) in the finite element space, there exists a constant \( C \) independent of \( h \) satisfying
\[ \| u_h \|_{l,p,0} \leq C h^{k-n+l/(p-1)} \| u_h \|_{l,0}. \] (51)

**Lemma 4** (see [25]). If \( V_h \) is a two-dimensional linear finite element space, then when \( C_0 = \sqrt{12} \) \( (C_0 = 12) \), there is
\[ \| \nabla u_h \|_{l,2} \leq C_0 h^{1/2} \| u_h \|_{l,2}. \] (52)
where \( m = 0, \ p = 2 \) in \( \| u \|_{m,p,0} \), and for any \( C < C_0 \) there is \( u_h \in V_h \) such that \([52]\) does not hold.

Based on Lemmas 2 and 3, a special case of the finite element inverse estimation inequality is given Lemma 4; that is, when \( V_h \) is a linear finite element space, the constant \( C_0 \) in the inverse estimation inequality is a specific number.

**Lemma 5** (see [26]). Given \( E(t) \leq \rho(t) + C \int_0^T E(s) \, ds \), thanks to the integral form of Gronwall’s inequality, it is derived that
\[ E(t) \leq \rho(t) e^{CT}, \quad 0 \leq t \leq T. \] (53)

4.1. In the One-Dimensional Case. The time-discrete scheme of equation (1) is shown in equation (30). When discussing the stability of equation (30), we used the finite element inverse estimation inequality, and the finite element inverse estimation inequality was discussed in the finite element space (see Lemmas 2 and 3). Therefore, we choose the finite element space. From Lemmas 2 and 3, the finite element space can be defined as \( V_h \subset H^1_{0} \), where
\[ V_h = \{ v \in H^1_{0}(\Omega) \cap C^0(\Omega) : \theta(\Omega) \mid v \mid e \in P_k(e), \forall e \in T_h \}. \] (54)

**Theorem 1.** Suppose \( \theta^m \in V_h \subset H^1_{0}(\Omega) \), \( m = 0, 1, 2, \ldots, n. \) \( \theta^m \) is the numerical solution of equation (1); then
\[ \| \theta^m \| \leq C \| \theta^0 \| + \lambda C \max_{0 \leq s \leq n} | f^i |, \] (55)
where \( C \) is a positive constant.

**Proof.** We will prove the above result by mathematical induction.

For \( m = 1 \), we have
\[ a_0^{(0)}(\theta^0, \theta^0) = a_0^{(0)}(\theta^0, \theta^0) - \lambda \left( D(\theta^0) \frac{\partial \theta^1}{\partial x} \right) + \lambda(\partial \theta^1 \frac{\partial \theta^0}{\partial x}) \] (57)
\[ - \lambda \left( K(\theta^0) \frac{\partial \theta^1}{\partial x} \right) + \lambda f^1, \theta^1 \right). \]
Due to \( 0 < m \leq D(\theta) \leq M, \| K(\theta) \| \leq L | \theta |, \) and \( | \theta' | \leq L, \)
\[ \| \theta^1 \| \leq a_0^{(0)}(\theta^0, \theta^0) + \lambda \left( M \left( \frac{\partial \theta^1}{\partial x} \right)^2 + \lambda f^1, \theta^1 \right). \] (58)
From Lemma 1, we have
\[
\|\theta^0\|^2 \leq (\theta^0, \theta^1) + \lambda \left( M, \left( \frac{\partial \theta^1}{\partial z} \right)^2 \right) + \lambda \left( f^1, \theta^1 \right).
\] (59)

Using Schwarz’s inequality and the inverse inequality in Lemmas 2 and 3, we obtain
\[
\|\theta^0\|^2 \leq \|\theta^0\| \|\theta^0\| + \lambda M \left( \frac{\partial \theta^1}{\partial z} \right)^2 + \lambda \max_{0 \leq z \leq m} f',
\] hence,
\[
\left( 1 - \lambda Mch^{-2} \right) \|\theta^0\| \leq \|\theta^0\| + \lambda \max_{0 \leq z \leq m} f',
\]
when \(1 - \lambda Mch^{-2} > 0\), then
\[
\|\theta^0\| \leq C \|\theta^0\| + \lambda C \max_{0 \leq z \leq m} f'.
\]

Suppose that now we have proven
\[
\|\theta^0\| \leq C \|\theta^0\| + \lambda C \max_{0 \leq z \leq m} f',
\]
then
\[
\|\theta^0\| \leq C \|\theta^0\| + \lambda C \max_{0 \leq z \leq m} f',
\]
and the proof is finished.

4.2. In the Two-Dimensional Case. The time-discrete scheme of equation (3) is shown in equation (41). When discussing the stability of equation (41), we choose the finite element space, which is defined as equation (56).

**Theorem 2.** Suppose \(\vartheta^m \in V_h \subset H^1_0(\Omega), m = 0, 1, 2, \ldots, n\). \(\vartheta^m\) is the numerical solution of equation (3); then
\[
\|\vartheta^n\| \leq p e^{CT},
\]
where \(C\) and \(p\) are positive constants.

**Proof.** Multiplying equation (41) by \(\vartheta^m\) and integrating on \(\Omega\), and then using Green’s formula, we have
\[
(\vartheta^m, \vartheta^m) = \sum_{k=1}^{m-1} \left( a_m^{(a)} - a_m^{(a)} \right)(\vartheta^0, \vartheta^m) + a_m^{(a)}(\vartheta^0, \vartheta^m)
- \lambda \left( D(\vartheta^0), \left( \frac{\partial \vartheta^m}{\partial z} \right)^2 \right) - \lambda \left( K(\vartheta^m), \left( \frac{\partial \vartheta^m}{\partial z} \right)^2 \right)
+ \lambda \left( f^m, \vartheta^m \right).
\]

By a derivation process similar to \(m = 0\), we obtain
\[
(1 - \lambda Mch^{-2}) \|\vartheta^m\|^2 \leq \sum_{k=1}^{m-1} \left( a_m^{(a)} - a_m^{(a)} \right)(\vartheta^0, \vartheta^m) + a_m^{(a)}(\vartheta^0, \vartheta^m)
+ \lambda \max_{0 \leq z \leq m} f'
\leq \sum_{k=1}^{m-1} \left( a_m^{(a)} - a_m^{(a)} \right)(\vartheta^0, \vartheta^m) + a_m^{(a)}(\vartheta^0, \vartheta^m)
+ \lambda \left( C, \left( \frac{\partial \vartheta^m}{\partial z} \right)^2 \right) + a_m^{(a)}(\vartheta^0, \vartheta^m)
\leq C \|\theta^0\| + \lambda C \max_{0 \leq z \leq m} f'.
\]

Due to \(1 - \lambda Mch^{-2} > 0\),
\[
\|\vartheta^m\| \leq C \|\theta^0\| + \lambda C \max_{0 \leq z \leq m} f',
\]
and the proof is finished.
\[ \|\theta^m\| \leq \frac{1}{1 - \lambda M c_i h^{-2} - \lambda L c_i h^{-1}} \sum_{k=1}^{m-1} (a_{m-k-1}^{(a)} - a_{m-k}^{(a)}) \|\phi_k\| + \frac{a_{m-1}^{(a)}}{1 - \lambda M c_i h^{-2} - \lambda L c_i h^{-1}} \|f^m\| + \frac{\lambda}{1 - \lambda M c_i h^{-2} - \lambda L c_i h^{-1}} \|f^m\|. \]  

(72)

Assume \( C_2 = \max_{1 \leq k \leq m-1} \{|a_{m-k-1}^{(a)} - a_{m-k}^{(a)}|\} \), there is

\[ \|\theta^m\| \leq \frac{C_1}{1 - \lambda M c_i h^{-2} - \lambda L c_i h^{-1}} \sum_{k=1}^{m-1} \|\phi_k\| + \frac{1}{1 - \lambda M c_i h^{-2} - \lambda L c_i h^{-1}} (a_{m-1}^{(a)} \|\theta^h\| + \|f^m\|) \]

\[ = C \sum_{k=1}^{m-1} \|\phi_k\| + D(a_{m-1}^{(a)} \|\theta^h\| + \|f^m\|) = C \sum_{k=1}^{m-1} \|\phi_k\| + \rho. \]  

(73)

i.e.,

\[ \|\theta^m\| \leq \rho + C \sum_{k=1}^{m-1} \|\phi_k\|. \]  

(74)

Applying Lemma 5, we obtain

\[ \|\theta^m\| \leq \rho e^{CT}. \]  

(75)

5. Results and Discussion

In this section, we show the results for two examples using the method described in previous sections. To show the accuracy of the proposed method, maximum absolute error and relative error are presented as

\[ \epsilon_1 = \max_{i \in N} |\theta(z_i) - \theta_{\text{exact}}(z_i)|, \]

\[ \epsilon_2 = \sqrt{\frac{\sum_{i=1}^{N} (\theta(z_i) - \theta_{\text{exact}}(z_i))^2}{\sum_{i=1}^{N} (\theta(z_i))^2}}, \]  

(76)

where \( \theta(z_i) \) and \( \theta_{\text{exact}}(z_i) \) for \( i = 1, 2, \ldots, N \) are computed by the exact and numerical solutions on points \( z_i \), respectively, and \( N \) is the number of nodal points.

Gaussian function has arbitrary order derivative. We choose Gaussian function as the weight function, and the basis function is quadratic basis function \( p^T = (1, x, x^2) \) in the example.

Example 1. Consider one-dimensional time fractional soil water movement equation

\[ C D^\alpha_t \theta = \frac{\partial}{\partial z} \left( D(\theta) \frac{\partial \theta}{\partial z} \right) + \frac{\partial K(\theta)}{\partial z} + f, \quad (z, t) \in [0, 1] \times [0, T], \]

\[ \theta(z, 0) = 0, \quad z \in [0, 1], \]

\[ \theta(0, t) = 0, \quad t \in [0, T), \]

\[ \theta(1, t) = 0, \quad t \in (0, T], \]  

(77)

Figure 1: Comparing the proposed method with the exact solution when \( \Delta T = 10^{-3} \) and the number of nodes is 21, where \( \alpha = 0.5 \) (a), \( \alpha = 0.8 \) (b).
where \( K(\theta) = \theta, D(\theta) = 0.001 \theta + 0.001 \), the exact solution is \( \theta = t^2 (z - z^2) \), and \( f(x) \) can be obtained by substituting the exact solution into the equation.

We take \( \Delta t = 10^{-3} \), the basis function is quadratic basis function \( p^T = (1, x, x^2) \) and scale is 2.5 in Example 1.

Figure 1 shows the comparison between the FPM and the exact solution at different times when \( \alpha = 0.5 \) and \( \alpha = 0.8 \), respectively. It can be seen from Figure 1 that the finite point numerical solution and the exact solution can still agree well even when \( T \) is large.

Table 1 shows the \( \varepsilon^2 \) errors of the FPM and the FDM under different \( \alpha \) when \( T = 1 \), \( \Delta t = 10^{-3} \), and the number of nodes is 11. It can be seen from Table 1 that as \( \alpha \) increases, the \( \varepsilon^2 \) errors of both the FPM and the FDM increase gradually, but the \( \varepsilon^2 \) errors of the FPM is significantly smaller than the FDM.

When \( \alpha = 0.8 \), Table 2 gives the \( \varepsilon^2 \) errors of the FPM and the FDM under different node numbers at \( T = 1 \). Table 3 gives the \( \varepsilon^2 \) errors of the FPM and the FDM at different times. Table 4 verifies the convergence order of the FPM. As can be seen from Table 2, with the increase of the number of spatial nodes, the numerical solution is closer to the exact solution, and the \( \varepsilon^2 \) errors of the FPM are still higher than those of the FDM. It can be seen from Table 3 that the \( \varepsilon^2 \) errors of the FPM and the FDM decrease gradually with the increase of time, but the results of proposed method are still better than those of the FDM and the \( \varepsilon^2 \) errors can still reach the order of \( 10^{-005} \) when \( T = 2 \), which shows that the proposed method can obtain relatively stable results in simulating water infiltration process. From Table 4, it can be seen that the convergence order is closer to 1.2 as the time step decreases when \( \alpha = 0.8 \), which shows that the convergence order is closer to the theoretical convergence order.

Example 2. Consider one-dimensional time fractional soil water movement equation:

\[
\frac{\varepsilon^2}{\partial \theta} \frac{\partial^\alpha \theta}{\partial x} + \frac{\partial}{\partial z} \left( D(\theta) \frac{\partial \theta}{\partial z} \right) + \frac{\partial K(\theta)}{\partial z} + f, \quad (x, z, t) \in [0, 1] \times [0, 1] \times [0, T],
\]

where \( K(\theta) = \theta, D(\theta) = 0.001 \theta + 0.001 \), the exact solution is \( \theta = t^2 (z - z^2) \), and \( f(x) \) can be obtained by substituting the exact solution into the equation.

We take \( \Delta t = 10^{-3} \), the basis function is quadratic basis function \( p^T = (1, x, x^2) \), and scale is 2 in Example 2.

When \( T = 1 \) and \( \alpha = 0.8 \), Figure 2 gives the comparison between the numerical solution of FPM and the exact solution when the number of nodes is \( 21 \times 21 \). Figure 3 gives the equipotential of the exact solution and the numerical solution when the number of nodes is \( 31 \times 31 \). From Figure 3, we can see that the numerical solution of FPM is basically consistent with the exact solution.

Table 5 shows the \( \varepsilon^2 \) errors of the FPM and the FDM under different \( \alpha \) when \( T = 1 \), \( \Delta t = 10^{-3} \), and the number of nodes is \( 21 \times 21 \). It can be seen from Table 5 that as \( \alpha \) increases, the \( \varepsilon^2 \) errors of the FPM is significantly smaller than the FDM. when \( \alpha = 0.8 \). Table 6 gives the \( \varepsilon^2 \) errors of the FPM and the FDM under different number of nodes. From Table 6, we can see that the \( \varepsilon^2 \) errors of proposed method and the FDM can reach the same order of magnitude when the number of nodes is small, but with the increase of the number of nodes, the errors of the FPM decreases faster than those of the FDM. Table 7 gives the \( \varepsilon^2 \) errors of the FPM and the FDM at different times. It can be seen from Table 7 that when \( T = 2 \), the results of the FPM are still better than those of the FDM, and the \( \varepsilon^2 \) errors can still reach the order of magnitude of \( 10^{-004} \). Table 8 verifies the convergence order of the FPM. From Table 8, it can be seen that the convergence order is closer to 1.2 as the time step decreases when \( \alpha = 0.8 \).
Table 1: Comparison of ε2 errors between the FPM and the FDM under different α, when \( T = 1, \Delta t = 10^{-3} \), and the number of nodes is 11.

Figure 2: Comparing the proposed method with the exact solution when \( T = 1, \Delta t = 10^{-3}, \alpha = 0.8 \), and the number of nodes is 21 × 21. (a) Exact solution. (b) FPM numerical solution.
6. Conclusions

In this article, the finite point method (FPM) was applied to the time fractional Richards’ equation in one- and two-dimensional cases. We have discretized the time fractional derivative using a finite difference formula and obtained a time-discrete scheme which proved to be conditionally stable. One- and two-dimensional numerical examples were given. Compared with finite difference method, the accuracy of finite point method was better than that of finite difference method. Meanwhile, numerical examples showed that the proposed method is simple and effective.
