Hyperammonemia is a serious complication of liver disease and may lead to encephalopathy and death. This study investigated the effects of Commiphora molmol resin on oxidative stress, inflammation, and hematological alterations in ammonium chloride-(NH4Cl-) induced hyperammonemic rats, with an emphasis on the glutamate-NO-cGMP and Nrf2/ARE/HO-1 signaling pathways. Rats received NH4Cl and C. molmol for 8 weeks. NH4Cl-induced rats showed significant increase in blood ammonia, liver function markers, and tumor necrosis factor-alpha (TNF-α). Concurrent supplementation of C. molmol significantly decreased circulating ammonia, liver function markers, and TNF-α in hyperammonemic rats. C. molmol suppressed lipid peroxidation and nitric oxide and enhanced the antioxidant defenses in the liver, kidney, and cerebrum of hyperammonemic rats. C. molmol significantly upregulated Nrf2 and HO-1 and decreased glutamine and nitric oxide synthase, soluble guanylate cyclase, and Na+/K+-ATPase expression in the cerebrum of NH4Cl-induced hyperammonemic rats. Hyperammonemia was also associated with hematomatological and coagulation system alterations. These alterations were reversed by C. molmol. Our findings demonstrated that C. molmol attenuates ammonia-induced liver injury, oxidative stress, inflammation, and hematological alterations. This study points to the modulatory effect of C. molmol on glutamate-NO-cGMP and Nrf2/ARE/HO-1 pathways in hyperammonemia. Therefore, C. molmol might be a promising protective agent against hyperammonemia.

1. Introduction

Hepatic encephalopathy (HE) is a serious complication of both acute and chronic liver diseases [1, 2]. HE has been estimated to occur in 10–50% of patients with transjugular intrahepatic portosystemic shunt and 30–45% of patients with cirrhosis, whereas minimal HE affects 20–60% of patients with liver disease [3]. Although the pathological mechanism of HE is not fully understood, ammonia is known to play a key role in HE [4]. Ammonia is a known neurotoxin and induces harmful effects to the central nervous system [5]. Blood ammonia level is strongly correlated with the
increased risk of HE and is therefore used as a diagnostic marker for encephalopathy [6]. Ammonia is normally detoxified in the liver via urea cycle, and if does not proceed properly, as in cases of liver failure or congenital defect of the urea cycle enzymes, ammonia increases and lead to HE [7].

The brain removes ammonia through glutamine synthesis driven by glutamine synthetase (GS). Therefore, high ammonia levels can increase glutamine synthesis and cause swelling of astrocytes and brain edema [8]. In addition, hyperammonemia can alter the mitochondrial function and neurotransmission and induce oxidative/nitrosative stress [9–11]. Hyperammonemia has been demonstrated to increase the activity of nitric oxide synthase (NOS) and subsequently nitric oxide (NO) production in the brain [12]. High levels of NO were associated with HE, hyperammonemic syndromes, and other disorders without significant neuronal damage [13, 14]. Moreover, ammonia-induced oxidative stress occurs due to increased production of reactive oxygen species (ROS) and subsequent damage of proteins, lipids, and DNA [15]. Previous studies have demonstrated increased ROS production and oxidative stress in hyperammonemia [10, 11, 16]. Hence, counteracting oxidative/nitrosative stress may represent a protective strategy against hyperammonemia-induced brain injury. In this context, several in vitro and in vivo studies have demonstrated the role of nuclear factor erythroid 2-related factor 2 (Nrf2)/antioxidant response element (ARE) signaling pathway as a contributor to the cellular responses to neuronal injury [17–20]. Through binding to the promoter sequence ARE, Nrf2 controls the expression of antioxidant, defensive, and detoxification genes to remove ROS and reactive nitrogen species (RNS) [21]. However, its role in hyperammonemia is still not fully understood.

Excess ammonia reduces glutamate uptake and increases extracellular glutamate levels [22], leading to activation of the N-methyl-D-aspartic acid (NMDA) glutamate receptor in the brain cortex [23]. Consequently, intracellular calcium (Ca2+) increases followed by increased NO production and activation of soluble guanylate cyclase (sGC) and subsequently increases cyclic guanosine monophosphate (cGMP) production [24]. Excess ammonia also increases the activity of Na+/K+-ATPase in the brain [25]; however, the underlying mechanism remains unclear. Increased activity of the brain Na+/K+-ATPase in hyperammonemia has been demonstrated in multiple previous studies [16, 26].

Current treatments used to reduce ammonia levels are of limited value, and therefore new psychopharmacological agents acting on cellular molecular targets involved in brain neurological alterations are required [27]. Medicinal plants and their derived bioactive phytochemicals have been gaining recognition in the treatment of neurological diseases. Commiphora molmol (family Burseraceae) is a shrub resembling tropical tree grows in dry forest and produces a resinous exudate called myrrh or oleo-gum resin [28]. Myrrh has been used traditionally for several centuries for the treatment of various diseases and has showed multiple beneficial effects, including antibacterial [29], hypoglycemic [30], anti-inflammatory [31], antioxidant [32], and hepatoprotective efficacies [33]. To the best of our knowledge, nothing has yet been reported on the possible protective effect of C. molmol resin against hyperammonemia. Therefore, the present study aimed to investigate the effects of C. molmol resin extract against ammonium chloride- (NH4Cl-) induced hyperammonemia in rats, pointing to the role of oxidative stress and inflammation, and the glutamate-NO-cGMP and Nrf2/ARE signaling pathways.

2. Materials and Methods

2.1. Preparation of C. molmol Extract and Assay of Radical Scavenging Activity. C. molmol resin was purchased from a local herbalist (Harraz Medicinal Plants Co., Cairo, Egypt) and was ground into fine powder. The resin powder was soaked in 90% ethanol for 24 h, filtered, and concentrated using a rotary evaporator at a temperature not exceeding 45°C. The scavenging activity of C. molmol extract against 2,2-diphenyl-1-picrylhydrazyl (DPPH) radicals was assayed according to the method of Kamel et al. [34] using vitamin C as antioxidant reference.

2.2. Experimental Animals and Treatments. Eight-week-old male albino Wistar rats (Rattus norvegicus) purchased from the Institute of Ophthalmology (Giza, Egypt) were used in the present investigation. The animals were housed in standard cages at 23 ± 2°C with a 12 h dark/light cycle. All animal procedures were approved by the Institutional Animal Ethics Committee of Beni-Suef University (Egypt).

The experimental rats were divided randomly into 4 groups as following:

- **Group I (control):** rats received intraperitoneal (i.p.) injection of 0.9% sodium chloride (NaCl) (3 times/week) and orally administered 0.5% carboxymethyl cellulose (CMC) daily for 8 weeks.
- **Group II (C. molmol):** rats received 0.9% NaCl (3 times/week) and orally administered 125 mg/kg body weight C. molmol extract [35] suspended in 0.5% CMC daily for 8 weeks.
- **Group III (NH4Cl):** rats received 100 mg/kg NH4Cl (Sisco Research Laboratories, Mumbai, India) dissolved in 0.9% NaCl (i.p., 3 times/week) [10] and orally administered 0.5% CMC daily for 8 weeks.
- **Group IV (NH4Cl + C. molmol):** rats received 100 mg/kg NH4Cl (i.p., 3 times/week) and orally administered 125 mg/kg body weight C. molmol extract suspended in 0.5% CMC daily for 8 weeks.

The doses were adjusted in accordance with changes in the body weight.

2.3. Samples Collection and Preparation. By the end of 8 weeks, the animals were fasted overnight and were then sacrificed, and samples were collected for analysis. Whole blood was collected for the assay of ammonia and hematological parameters. Citrated blood samples were used to assay prothrombin time (PT) and activated partial thromboplastin time (aPTT). Other blood samples were left to coagulate for serum preparation.

The liver, kidney, and cerebrum were immediately excised, washed in cold phosphate-buffered saline (PBS),
and weighed. Samples from the liver, kidney, and cerebrum were homogenized in cold PBS, centrifuged, and kept frozen for the determination of lipid peroxidation, NO, and antioxidants. Homogenized cerebrum samples were also used to assay glutamine and Na⁺/K⁺-ATPase. Other samples from the cerebrum were collected and kept at −80°C for RNA isolation and Western blot analysis.

2.4. Biochemical Assays

2.4.1. Determination of Ammonia, Urea, Liver Function Markers, and TNF-α. Blood ammonia was estimated using reagent kit purchased from Spinreact (Spain), according to the method of da Fonseca-Wollheim [36].

Circulating levels of ALT and AST were determined following the method of Schumann and Klauke [37] whereas ALP was assayed according to the method of Wenger et al. [38]. The assay kits were purchased from Spinreact (Spain).

Serum TNF-α levels were estimated using specific ELISA kits (R&D Systems, USA), according to the manufacturer’s instructions.

2.4.2. Assay of Oxidative Stress and Antioxidant Defenses. Samples from the liver, kidney, and cerebrum were used to assays lipid peroxidation following the method of Preuss et al. [39] and NO using Griess reagent. Reduced glutathione (GSH) [40] and activity of superoxide dismutase (SOD) [41], catalase (CAT) [42], and glutathione peroxidase (GPx) [43] were also determined in the liver, kidney, and cerebrum homogenates.

2.4.3. Assay of Glutamine Level and Na⁺/K⁺-ATPase Activity. Glutamine concentration in the cerebrum of control and C. molmol Decreases Circulating TNF-α.

2.6. Gene Expression Analysis. Reverse transcriptase polymerase chain reaction (RT-PCR) was used to determine the effect of C. molmol on Nrf2 and HO-1 expression in the cerebrum, Western blotting was used as we previously reported [48]. In brief, samples from the cerebrum were homogenized in RIPA buffer with protease inhibitors and centrifuged, and protein concentration was determined in the homogenates using Bradford reagent [49]. To determine Nrf2, nuclear proteins were extracted using a commercial kit purchased from Beyotime (China). The samples were electrophoresed on SDS/PAGE, transferred to PVDF membranes, blocked, and incubated with primary antibodies for Nrf2, lamin B, HO-1, and β-actin (Santa Cruz Biotechnology, USA). After washing, the membranes were incubated with the secondary antibodies, washed, and then developed using enhanced chemiluminescence kit (Bio-Rad, USA). The intensity of bands was determined and quantified using ImageJ (version 1.32j, NIH, USA).

3. Results

3.1. Effect of C. molmol on Body Weight Changes in Hyperammonemic Rats. Initial body weight showed nonsignificant (P > 0.05) changes between all experimental groups. Rats received NH₄Cl administration for 8 weeks which showed a significant (P < 0.05) decrease in body weight when compared with the control rats (Figure 1). Concurrent administration of C. molmol significantly (P < 0.05) improved body weight in NH₄Cl-induced hyperammonemic rats, while exerting nonsignificant effect when administered to control rats.

3.2. Effect of C. molmol on Blood Ammonia and Liver Function Markers in Hyperammonemic Rats. Hyperammonemic rats showed a significant (P < 0.001) increase in blood ammonia when compared with the control group of rats. Oral administration of C. molmol extract to hyperammonemic rats significantly (P < 0.001) ameliorated circulating levels of ammonia when compared with the hyperammonemic group (Table 2).

NH₄Cl-induced hyperammonemia in rats produced a significant (P < 0.001) increase in circulating levels of the liver function markers, ALT, AST, and ALP. Treatment of the hyperammonemic rats with C. molmol significantly (P < 0.001) improved the circulating levels of ALT, AST, and ALP (Table 2). Rats received C. molmol alone exhibited nonsignificant changes in blood ammonia, ALT, AST, and ALP when compared with the control rats.

3.3. C. molmol Decreases Circulating TNF-α Levels in Hyperammonemic Rats. Serum levels of the proinflammatory cytokine TNF-α showed a significant (P < 0.001) increase in NH₄Cl-induced hyperammonemic rats when compared with the control group (Table 2). Oral supplementation of C. molmol resin extract significantly (P < 0.01) decreased the
circulating levels of TNF-α in hyperammonemic rats, with no effect on normal rats.

3.4. Effect of C. molmol on Lipid Peroxidation, NO, and Antioxidant Defenses in the Liver of Hyperammonemic Rats. Hyperammonemic rats showed a significant (P < 0.001) increase in lipid peroxidation (Figure 2(a)) and NO levels (Figure 2(b)) in the liver of rats when compared with the control group. Treatment of the hyperammonemic rats with C. molmol markedly decreased liver lipid peroxidation (P < 0.001) and NO (P < 0.001) levels.

On the other hand, hyperammonemic rats exhibited a significant (P < 0.01) decrease in liver GSH content, an effect that was significantly (P < 0.05) prevented by C. molmol (Figure 2(c)). Similarly, hyperammonemia was associated with significant decline in the activity of SOD (P < 0.01; Figure 2(d)), CAT (P < 0.01; Figure 2(e)), and GPx (P < 0.001; Figure 2(f)) in the liver of rats. Oral administration of C. molmol significantly alleviated the activity of SOD (P < 0.05), CAT (P < 0.01), and GPx (P < 0.001) in the liver of hyperammonemic rats.

Oral administration of C. molmol to normal rats did not affect liver lipid peroxidation, NO, and antioxidant defenses.

3.5. Effect of C. molmol on Lipid Peroxidation, NO, and Antioxidant Defenses in the Kidney of Hyperammonemic Rats. Lipid peroxidation and NO levels showed a significant (P < 0.001) increase in the kidney of hyperammonemic rats when compared with the control group. Treatment of the hyperammonemic rats with C. molmol significantly (P < 0.001) reduced both lipid peroxidation (Figure 3(a)) and NO (Figure 3(b)) in the kidney. C. molmol administration to normal rats exerted nonsignificant (P > 0.05) effect on kidney lipid peroxidation and NO.

GSH levels showed a significant (P < 0.01) decrease in the kidney of hyperammonemic rats when compared with the control rats, an effect that was markedly (P < 0.01) prevented by C. molmol extract as depicted in Figure 3(c). Similarly, hyperammonemic rats exhibited significantly declined activity of kidney SOD (P < 0.001, Figure 3(d)), CAT (P < 0.01, Figure 3(e)), and GPx (P < 0.001, Figure 3(f)) when compared with the control group. C. molmol administration significantly improved the activity of SOD (P < 0.05), CAT (P < 0.05), and GPx (P < 0.01) in kidneys of hyperammonemic rats, with no effect on normal rats.

3.6. Effect of C. molmol on Lipid Peroxidation, NO, and Antioxidant Defenses in the Cerebrum of Hyperammonemic Rats. NH₄Cl administration induced a significant (P < 0.001) increase in the levels of lipid peroxidation (Figure 4(a)) and NO (Figure 4(b)) in the cerebrum of rats when compared with the control group. In addition, hyperammonemic rats exhibited marked decrease in the cerebral GSH levels (P < 0.01; Figure 4(c)), and the activity of SOD (P < 0.01; Figure 4(d)), CAT (P < 0.01; Figure 4(e)), and GPx (P < 0.001; Figure 4(f)). Treatment of the hyperammonemic rats with C. molmol significantly decreased lipid peroxidation (P < 0.001) and NO (P < 0.01) and significantly improved GSH (P < 0.01), SOD (P < 0.05), CAT (P < 0.05), and GPx (P < 0.01) in the cerebrum. Oral supplementation of C. molmol did not affect lipid peroxidation, NO, and antioxidant defenses in the cerebrum of normal rats.

3.7. C. molmol Upregulates the Nrf2/ARE/HO-1 Pathway in the Cerebrum of Hyperammonemic Rats. To investigate the effect of C. molmol resin extract on the Nrf2/ARE/HO-1 pathway in hyperammonemic rats, the protein expression of Nrf2 and HO-1 was determined in the cerebrum using Western blotting assay.

NH₄Cl-induced hyperammonemia in rats induced a significant (P < 0.001) downregulation of cerebral Nrf2 expression when compared with the control group of rats (Figure 5(a)). Concurrent administration of C. molmol resin

Data are expressed as mean ± SEM (*N* = 6). ***P < 0.001 versus control, and ##P < 0.01 and ###P < 0.001 versus NH₄Cl.

Figure 2: Effect of *C. molmol* resin extract on (a) lipid peroxidation, (b) nitric oxide, (c) GSH, (d) SOD, (e) CAT, and (f) GPx in the liver of NH₄Cl-induced hyperammonemic rats. Data are expressed as mean ± SEM (*N* = 6). *P < 0.05, **P < 0.01, and ***P < 0.001. MDA, malondialdehyde; NO, nitric oxide; GSH, reduced glutathione; SOD, superoxide dismutase; CAT, catalase; GPx, glutathione peroxidase.
extract significantly ($P < 0.001$) increased Nrf2 expression in the cerebrum of hyperammonemic rats. Similarly, HO-1 expression showed a significant ($P < 0.001$) downregulation in the cerebrum of NH$_4$Cl-induced hyperammonemic rats when compared with the control rats as depicted in Figure 5(b). C. molmol resin supplementation significantly ($P < 0.001$) ameliorated the expression of HO-1 in the cerebrum of hyperammonemic rats. Oral supplementation of C. molmol did not induce significant changes in cerebral Nrf2 and HO-1 expression.

3.8. C. molmol Prevents Hyperammonemia-Associated Hematological Alterations in Rats. To evaluate the effect of C. molmol extract on hyperammonemia-associated hematological alteration, RBCs, Hb, WBCs, and platelets were determined in the control and hyperammonemic rats.
Hyperammonemic rats exhibited a significant ($P < 0.01$) decrease in the number of erythrocytes (Figure 6(a)) and in the Hb content (Figure 6(b)) when compared with the control rats. On the other hand, NH$_4$Cl-induced hyperammonemia was associated with significant ($P < 0.001$) leukocytosis (Figure 6(c)). $C. molmol$ administration markedly prevented hyperammonemia-induced anemia ($P < 0.05$) and leukocytosis ($P < 0.001$). MDA, malondialdehyde; NO, nitric oxide; GSH, reduced glutathione; SOD, superoxide dismutase; CAT, catalase; GPx, glutathione peroxidase.

To examine hyperammonemia-induced changes in the coagulation system and the effect of $C. molmol$, we determined PT and aPTT. Hyperammonemic rats exhibited a significant ($P < 0.01$) prolongation of PT (Figure 6(e)) and aPTT (Figure 6(f)), an effect that was markedly ($P < 0.01$) reversed by $C. molmol$. Oxidative Medicine and Cellular Longevity
Of note, *C. molmol* did not induce any significant changes on hematological parameters of normal rats.

3.9. *C. molmol* Downregulates NOS1, sGC, and Na⁺/K⁺-ATPase and Decreases Glutamine in the Cerebrum of Hyperammonemic Rats. NOS1 mRNA expression showed a significant (*P* < 0.001) increase in the cerebrum of NH₄Cl-induced hyperammonemic rats when compared with the control group (Figure 7(a)). Concurrent supplementation of *C. molmol* significantly (*P* < 0.001) improved the expression of NOS1 mRNA in the cerebrum of hyperammonemic rats.

Hyperammonemic rats exhibited a significant (*P* < 0.001) upregulation in the expression of sGC mRNA, an effect that was significantly (*P* < 0.001) ameliorated by *C. molmol* (Figure 7(b)). Glutamine levels as well showed a significant (*P* < 0.001) increase in the cerebrum of NH₄Cl-induced hyperammonemic rats when compared with the control rats (Figure 7(c)). Concurrent administration of *C. molmol* significantly (*P* < 0.001) decreased cerebral glutamine levels in NH₄Cl-induced hyperammonemic rats.

NH₄Cl-induced hyperammonemia induced a significant (*P* < 0.001) increase in both the expression and activity Na⁺/K⁺-ATPase in the cerebrum of rats. Oral supplementation of *C. molmol* to hyperammonemic rats significantly improved the expression (*P* < 0.01) and activity (*P* < 0.001) of the cerebral Na⁺/K⁺-ATPase as represented in Figures 7(d) and 7(e), respectively.

Oral supplementation of *C. molmol* did not affect the gene expression of NOS1, sGC, Na⁺/K⁺-ATPase, or glutamine levels in the cerebrum of normal rats.

### 4. Discussion

*C. molmol* has showed multiple therapeutic effects; however, nothing has yet been reported on its protective effect against hyperammonemia. The present study shows for the first time the protective effect of *C. molmol* resin extract against excess ammonia-induced alterations, pointing to the role of Nrf2/HO-1 pathway.

An initial objective of this study was to investigate the protective activity of *C. molmol* resin extract against NH₄Cl-induced liver injury. The liver plays a central role in detoxification of both endogenous and exogenous toxins. This detoxification capacity is hampered upon liver injury, and the body is exposed to the harmful effects of toxicants. Hyperammonemia occurs as a consequence of liver failure [7]. In the present investigation, increased circulating levels of ammonia indicate liver damage induced by ammonia intoxication in rats as we previously reported [10, 11]. Excess ammonia-induced liver injury was confirmed by increased circulating liver-specific marker enzymes ALT, AST, and ALP. In NH₄Cl-induced animal model, hyperammonemia occurs as a consequence of liver damage induced by injection of NH₄Cl. Hyperammonemia induces liver damage which may contribute to or exacerbate hyperammonemia and other alterations resulting from liver damage. We have previously reported increased circulating levels of ALT, AST, and ALP in NH₄Cl-induced hyperammonemic rats [10]. Elevated liver marker enzymes in serum is an indicator for the assessment of hepatocellular damage [50]. *C. molmol* resin extract significantly ameliorated body weight and decreased blood ammonia levels and circulating levels of ALT, AST, and ALP in hyperammonemic rats. These findings suggest hepatoprotective and membrane-stabilizing potentials of *C. molmol*. Accordingly, *C. molmol* resin protected the liver against ethanol-induced hepatotoxicity in rats and decreased the circulating levels of ALT, AST, and ALP [51]. In addition, treatment with *C. molmol* resin extract decreased circulating ALT and AST in carbon tetrachloride- (CCL₄) [52] and D-GalN/LPS-induced [53] liver injury in rats and in a rodent model of chemically induced hepatocarcinogenesis [54]. The declined body weight in NH₄Cl-induced hyperammonemic rats could
be explained by the decreased body fat content. Hyperammonemia has been reported to alter lipid metabolism and significantly decrease body lipid content, leading to declined body weight [55]. Alleviated body weight by *C. molmol* resin extract in this study could be attributed to the ameliorated lipid metabolism. However, further studies are required to better explain the possible role of *C. molmol* in ameliorating body weight in hyperammonemic rats.

Hyperammonemic rats in the present study exhibited a marked increase in the circulating levels of TNF-α as we recently reported [11]. Although the precise interaction between inflammation and hyperammonemia is unclear,
inflammation appears to play important role in the pathogenesis of HE [56–58]. In this context, studies have showed a strong positive correlation between inflammation and HE [59, 60]. In patients with liver cirrhosis, elevated circulating levels of the proinflammatory cytokine TNF-α were recorded [59, 60]. Shawcross et al. [61] proposed the crucial role of inflammation in hyperammonemia-associated neuropsychological alterations. Hence, attenuation of inflammation,
particularly mediated by TNFα, may reduce or prevent hyperammonemia. This notion is supported by the findings of Chung et al. [62] who showed the ability of indomethacin, a nonsteroidal anti-inflammatory drug (NSAID), to prevent ammonia-induced brain edema after portacaval anastomosis in rats. In addition, we have demonstrated that the ameliorated blood ammonia levels was associated with decreased circulating levels of TNF-α in NH₄Cl-induced hyperammonemia in rats [11].

Here, C. molmol resin extract significantly decreased serum levels of TNF-α, demonstrating that its anti-inflammatory effect plays a role in attenuating hyperammonemia. The anti-inflammatory efficacy of C. molmol has been reported in different studies. In a rat model of formalin-induced hind paw edema, Shalaby and Hammouda [35] showed that C. molmol exerted a potent anti-inflammatory effect. This effect has been attributed to the reduced production of prostaglandins as reported by Su et al. [63]. Also, Ahmad et al. [53] showed that myrrh attenuated inflammation in a rat model of D-GalN/LPS-induced hepatic injury. Recently, Fatani et al. [64] showed the anti-inflammatory efficacy of C. molmol in acetic acid-induced ulcerative colitis in rats. We have recently demonstrated the potent anti-inflammatory effect of C. molmol resin extract in a rat model of chemically induced hepatocarcinogenesis [54]. These studies support the idea that attenuation of inflammation has a role in the protective mechanism of C. molmol against hyperammonemia.

Attenuation of oxidative/nitrosative stress is another mechanism we hypothesized to mediate the protective effect of C. molmol resin extract against NH₄Cl-induced hyperammonemia in rats. In animal models, excess ammonia provokes excessive production of ROS [15] which initiate lipid peroxidation. Here, hyperammonemic rats exhibited marked increase in lipid peroxidation levels in the liver, kidney, and cerebrum. Previous research from our lab showed significant increase in lipid peroxidation in the liver, brain, and kidney of NH₄Cl-induced hyperammonemic rats [10, 11]. Other studies have reported increased lipid peroxidation in animal models of hyperammonemia [16, 65, 66]. Moreover, NH₄Cl-induced hyperammonemic rats showed a marked increase in NO levels in the liver, kidney, and cerebrum. The increased NO production in the brain is a direct result of the upregulated nNOS in hyperammonemic rats. Accordingly, Ramakrishnan et al. [16] have reported increased expression of nNOS in the brain of NH₄Cl-induced rats. Hyperammonemia is known to activate nNOS and increase NO production in the brain. The excessive production of NO can induce neuronal damage [12].

Interestingly, C. molmol resin significantly alleviated lipid peroxidation in the liver, kidney, and cerebrum of hyperammonemic rats, demonstrating a radical scavenging efficacy. In addition, C. molmol significantly decreased NO production which is associated with the decreased nNOS expression. In accordance, supplementation of C. molmol to rats with ulcerative colitis [64], ethanol- [51] and lead-induced liver injury [32], and hepatocarcinogenesis [54] significantly decreased lipid peroxidation and NO levels. Moreover, C. molmol significantly enhances both enzymatic and nonenzymatic antioxidant defenses in the liver, kidney, and cerebrum of hyperammonemic rats. These antioxidants play key roles in protecting the body against free radicals. Previous studies have reported declined GSH, SOD, CAT, and GPx in the liver, brain, and kidney of NH₄Cl-induced hyperammonemic rats [10, 11, 16]. Declined antioxidant defense mechanisms in hyperammonemia can aggravate ROS-induced tissue damage. Along with reducing lipid peroxidation and NO, C. molmol has been reported to enhance the antioxidant defenses in different tissues of rats [32, 51, 54, 64].

The in vivo antioxidant activity of C. molmol resin extract is in positive correlation with the in vitro data. Our findings showed a significant antioxidant and radical scavenging efficacies of C. molmol resin extract evidenced by the DPPH assay (Supplementary Figure I available online at https://doi.org/10.1155/2017/7369671). The antioxidant activity of C. molmol is due to its rich content of bioactive molecules. Phytochemical analysis of C. molmol resin showed the presence of active constituents with antioxidant activity. These bioactive constituents include limonene, m-cresol, eugenol, comphoric acids, furanosesquiterpenes, pinene, terpenoids, and cuminic aldehyde [67, 68]. In addition, the study of Mahboubi and Kazempour [69] showed the presence of phenolic and flavonoid compounds in C. molmol resin ethanolic extract. Phenolic compounds are well known for their potent antioxidant and radical scavenging properties [10, 34, 70, 71].

In addition to its radical scavenging property, we hypothesized that C. molmol resin extract can enhance antioxidant defenses and abrogate oxidative stress through activation of Nrf2/ARE-1 signaling. The possible involvement of Nrf2 activation in mediating the protective activity of C. molmol resin against hyperammonemia has not been previously investigated. The current findings showed a significant decline in Nrf2 expression in the cerebrum of hyperammonemic rats. This downregulation has been markedly reversed following treatment with C. molmol resin extract. The results also showed that HO-1 gene expression was upregulated in the cerebrum of hyperammonemic rats treated with C. molmol resin extract. These findings highlight that activation of the Nrf2/ARE/HO-1 signaling pathway participates in the neuroprotective effect of C. molmol resin extract against hyperammonemia-induced injury. Nrf2 is known to be activated by ROS and then dissociates from Keap1 and translocates to the nucleus where it binds to ARE and activates the transcription of antioxidant and cytoprotective proteins including HO-1, CAT, SOD, and GPx [21]. Although activated by ROS, Nrf2 showed a significant decline in the cerebrum of hyperammonemic rats exhibiting oxidative stress. This was further confirmed by the declined HO-1 expression in the cerebrum of hyperammonemic rats. Moreover, the activity of antioxidant defenses in the cerebrum was strongly correlated with these findings. An explanation for this declined expression of Nrf2 could be the chronic and surplus production of ROS. This notion is supported by our recent findings where we demonstrated downregulation of the Nrf2/ARE/HO-1 pathway in different conditions with excessive production of ROS [34, 48, 72–74]. Furthermore, the anti-inflammatory effect of C. molmol resin extract could be attributed, at least in part, to the activation of Nrf2.
Multiple studies have demonstrated the anti-inflammatory role of Nrf2. Knockout of Nrf2 has been associated with reduced anti-inflammatory efficacy of the antioxidant curcumin [75]. In addition, activation of Nrf2 blocked the transcription of IL-6 and IL-1β in macrophages [76].

The effect of C. molmol resin on hematological alterations in hyperammonemia was one of our targets in this study; however, reports about hematological alterations in hyperammonemia are very few. Assessment of hematological parameters represents a powerful tool and an earlier indicator to evaluate the deleterious effects of drugs [77]. In the present study, administration of C. molmol to normal rats did not affect the hematological and coagulation system parameters, whereas hyperammonemic rats exhibited anemia, leukocytosis, thrombocytopenia, and prolonged PT and aPTT. Hematological abnormalities occur frequently in liver disease conditions [78]. In support of our findings, Kalaitzakis et al. [79] have demonstrated that HE is related to anemia in liver transplant candidates with cirrhosis. The recorded anemia in hyperammonemic rats could also be a consequence of the increased ROS production. ROS can decrease cellular deformability and damage erythrocytes via induction of membrane lipid peroxidation and rigidity [80]. In addition, liver disease is known to be associated with defects of blood coagulation as a consequence of thrombocytopenia, endothelial dysfunction, and deficiencies of coagulation factors. Low circulating levels of the coagulation factors are associated with prolongation of PT and aPTT [81]. Here, hyperammonemic rats exhibited thrombocytopenia and prolonged PT and aPTT. Furthermore, hyperammonemic rats showed leukocytosis. Accordingly, Choi et al. [82] reported mild leukocytosis in hyperammonemic patients with ornithine carbamoyltransferase deficiency and Aggarwal et al. [78] demonstrated a significant association of leukocytosis with HE. Interestingly, C. molmol prevented all hematological alterations in hyperammonemic rats. These findings could be a direct result of the prevention of hyperammonemia and attenuation of liver injury, oxidative stress, and inflammation.

Glutamine is a neutral amino acid and functions normally as ammonia carrier in the CNS [83]. Because the brain does not convert ammonia into urea, ammonia is exclusively removed by GS located in astrocytes. Thus, glutamine synthesis is an essential process for the brain to detoxify excess ammonia in liver failure [84]. In hyperammonemic conditions, the metabolism of ammonia to glutamine is followed by an osmotic disturbance, altered cerebral blood flow, oxidative stress, and edema. Other factors including systemic inflammation may contribute to the excess ammonia-induced cerebral alterations [85]. NH₄Cl-induced hyperammonemic rats in the present investigation showed a marked increase in cerebral glutamine levels and the expression of sGC. Excess ammonia has been reported to activate NMDA receptors in the brain cortex [23], followed by increased intracellular Ca²⁺, increased NO production, and activation of sGC [24]. Interestingly, C. molmol supplemented hyperammonemic rats showed a marked decrease in cerebral glutamine levels and downregulated sGC. These findings could be attributed to the ability of C. molmol to decrease ammonia levels, oxidative stress, and nNOS expression. Therefore, the protective effect of C. molmol resin extract against hyperammonemia is illustrated, at least in part, through inhibiting NMDA receptors and modulation of the glutamate-NO-cGMP pathway.

Excess ammonia can also alter the ionic shifts and affect membrane potential of nerve cells. Here, NH₄Cl-induced hyperammonemic rats exhibited significantly increased expression and activity of the cerebral Na⁺/K⁺-ATPase. Previous studies have showed similar findings in hyperammonemic brain conditions [16, 25, 26]. The exact underlying mechanism of the activated Na⁺/K⁺-ATPase in hyperammonemia is not fully understood. Kosenko et al. [86] proposed that the activation of Na⁺/K⁺-ATPase is a result of decreased phosphorylation by protein kinase C (PKC). In addition, the activity of Na⁺/K⁺-ATPase was increased in cerebral cortex following exposure to millimolar concentrations of NH₄Cl [87]. C. molmol supplementation markedly ameliorated both the expression and the activity of Na⁺/K⁺-ATPase in the cerebrum of hyperammonemic rats. These findings added support to the protective role of C. molmol against the deleterious effects of hyperammonemia.

In conclusion, our study shows for the first time that C. molmol resin extract protects against excess ammonia through attenuation of oxidative stress and inflammation and modulation of the glutamate-NO-cGMP pathway. This investigation also confers information that C. molmol may be an effective neuroprotective therapeutic agent with a potential mechanism of upregulation Nrf2/ARE/HO-1 pathway and consequently enhances the antioxidant defenses. C. molmol ameliorated both the activity and the expression of Na⁺/K⁺-ATPase and prevented hematological alterations in cases of hyperammonemia and hepatic failure. Therefore, C. molmol resin may represent a promising protective agent against hyperammonemia, pending further detailed mechanistic studies. This study may serve as a base for future investigations exploring Nrf2-activating agents as therapeutics for hyperammonemia.

Conflicts of Interest

The authors declare that they have no conflict of interests.

Acknowledgments

The authors would like to thank the Deanship of Scientific Research at Princess Nourah Bint Abdulrahman University for funding this work through the Research Groups Program Grant no. RG-1438-002.
