Intensive physical exercise may cause increase oxidative stress and muscular injury in elite football athletes. The aim of this study was to exploit the effect of cocoa polyphenols on oxidative stress and muscular injuries induced by intensive physical exercise in elite football players. Oxidant/antioxidant status and markers of muscle damage were evaluated in 24 elite football players and 15 controls. Furthermore, the 24 elite football players were randomly assigned to either a dark chocolate (>85% cocoa) intake (n = 12) or a control group (n = 12) for 30 days in a randomized controlled trial. Oxidative stress, antioxidant status, and muscle damage were assessed at baseline and after 30 days of chocolate intake. Compared to controls, elite football players showed lower antioxidant power and higher oxidative stress paralleled by an increase in muscle damage markers. After 30 days of dark chocolate intake, an increased antioxidant power was found in elite athletes assuming dark chocolate. Moreover, a significant reduction in muscle damage markers (CK and LDH, \( p < 0.001 \)) was observed. In the control group, no changes were observed with the exception of an increase in sNox2-dp, \( \text{H}_2\text{O}_2 \), and myoglobin. A simple linear regression analysis showed that sNox2-dp was associated with a significant increase in muscle damage biomarker release (\( p = 0.001 \)). An in vitro study also confirmed that polyphenol extracts significantly decreased oxidative stress in murine myoblast cell line C2C12-derived. These results indicate that polyphenol-rich nutrient supplementation by means of dark chocolate positively modulates redox status and reduced exercise-induced muscular injury biomarkers in elite football athletes. This trial is registered with NCT03288623.

1. Introduction

Intensive physical exercise may increase oxidative stress and cause muscular injury in elite athletes [1]. This represents a significant problem for professional football players representing more than one third of all time-loss injuries and causing more than a quarter of the total injury-dependent absence in high-level European professional football clubs [2]. Consequently, the overall burden of muscle injuries is the main reason for player unavailability in training and official matches for professional football clubs [3]. Accordingly, injuries during a regular season or a particular tournament
can have considerable impact on team performance as well as on the economics of the club. Hereafter, prevention and reduction of muscle injuries in professional football should be of paramount importance.

The generation of reactive oxygen species (ROS) is a fundamental and physiological process of normal human biology. However, when ROS production and endogenous antioxidant ability are imbalanced, a maladaptive biological response occurs leading to both oxidative stress and inflammation [4, 5]. In muscle cells, aerobic energy production generates a significant amount of ROS, which can increase up to 10- to 20-fold during physical exercise [6]. Notably, previous evidence suggests that high ROS levels are able to induce muscular injury [1, 7, 8] with a consequent decrease in physical performance [9]. Several mechanisms contribute to the generation of ROS in skeletal muscles in response to intensive exercise. Among them, NADPH oxidase-derived ROS contribution [4, 5]. In muscle cells, aerobic energy production generates a significant amount of ROS, which can increase up to 10- to 20-fold during physical exercise [6]. Notably, previous evidence suggests that high ROS levels are able to induce muscular injury [1, 7, 8] with a consequent decrease in physical performance [9]. Several mechanisms contribute to the generation of ROS in skeletal muscles in response to intensive exercise. Among them, NADPH oxidase-derived ROS production and endogenous antioxidants may be of paramount importance. Hereafter, prevention and reduction of muscle injuries in professional football should be a critical concern.

Many studies have identified the potential antioxidant effect of polyphenols, a large group of natural compounds found in food and beverages [11]. Banerjee et al. highlighted that a supplementation with antioxidants is able to accelerate recovery from fatigue and to prevent exercise tissue damage [12]. Moreover, supplementation with other antioxidant nutrients, such as vitamin C and vitamin E, has been able to prevent exercise-induced oxidative damage but not inflammation in ultra-marathon runners [13]. Finally, previous work demonstrated a reduced exercise-induced muscular injury and a downregulation of monocytes expressing toll-like receptor 4 in kendo athletes by means of coenzyme Q10 administration [14, 15]. Overall, these data indicate that the administration of antioxidant nutrients may be a beneficial intervention to reduce the rate of muscular injury in endurance athletes. Cocoa may be appropriate for this purpose since it is a polyphenol-rich nutrient eliciting antioxidant effects [16]. A recent paper demonstrated that acute cocoa-derived flavonoid intake may reduce oxidative stress and muscle damage induced by exercise [17]. However, there are few studies examining the effect of chronic cocoa flavonoid intake during exercise training.

Accordingly, the purpose of this study was to exploit the effect of chronic dark chocolate supplementation on muscular injury and oxidative stress during training exercise in elite football players.

2. Material and Methods

The study was performed on 24 young (17.2 ± 0.7 years) elite male football players during the first month of the regular season and 15 physically active male subjects who did not practice football but practice aerobic sports such as running, swimming, or gymnastics (engaging in at least 3-day-week⁻¹ of moderate-to-intense physical activity, ranging from 3.0 to 6.0 METs and/or >6.0 METs) (24.8 ± 3.5 years) (Table 1). Players had at least 10 years of previous football training and were members of the Italian first-league A.S. Roma youth (17-19 years) team (Primavera). They were engaged in a 120-minute training (including a 15-minute warm-up, 30-minute technical/tactical skills, 30-minute aerobic training reaching 75% of the maximal heart rate, 30-minute strength training, and 15-minute cooldown) 6 times per week and a 90-minute match per week. The training program of the youth team was the same of the first A.S. Roma team (Serie A league). During the study, two players of the youth team also made their debut in the Serie A league with the first team and played regularly with the first team.

All participants and the head coach were explained the study’s purposes, risks, and benefits; they were familiarized with the study’s protocol during the pre-season screening; and they gave a written informed consent. The institutional review board approved this study (C.E. 4662), and the randomized controlled trial was registered on ClinicalTrials.gov (Identifier: NCT03288623).

Elite male athlete volunteers, aged between 18 and 35 years, were included in the study. Subjects were excluded if they suffer from an allergy to cocoa or any of the ingredients contained within either of the chocolate bars; they have a low platelet count (<170 x 10⁹/L); they are taking aspirin or aspirin-containing drugs, other anti-inflammatory drugs, or any drugs or herbal medicines known to alter platelet function or the haemostatic system in general (without a minimum washout period of one month); they are taking fish oils or evening primrose oil, or fat-soluble vitamin supplements within the last 4 weeks; they have unsuitable veins for blood sampling and/or cannulation; they have a BMI below 18 or above 35 kg/m²; they are taking any medicine

WBC: white blood cells; PLT: platelet; RBC: red blood cells; BMI: body mass index; LDH: lactate dehydrogenase; CK: creatine kinase; HBA: hydrogen peroxide (H₂O₂) breakdown activity.
known to affect lipid and/or glucose metabolism; they are suffering from alcohol or any other substance abuse or are having eating disorders; they have any known clinical signs of diabetes, hypertension, renal, hepatic, and haematological diseases, gastrointestinal disorders, endocrine disorders, coronary heart disease, infection, or cancer.

2.1. Study Design. In the first phase, we performed a cross-sectional study to compare oxidative stress, as assessed by blood levels of soluble Nox2 (sNox2-dp), H$_2$O$_2$ production, H$_2$O$_2$ breakdown activity (HBA) which is a method evaluating the antioxidant capacity of serum, and markers of muscle damage such as creatine kinase (CK), lactate dehydrogenase (LDH), and myoglobin in 24 young well-trained male elite football athletes and 15 sex-matched amateur controls. In the second phase, we performed a randomized controlled trial in elite football athletes to investigate the effect of daily supplementation with normal diet and 40 g of dark chocolate (20 g every 12h) vs normal diet, for 30 days, on markers of oxidative stress and muscle damage.

Elite football athletes were randomly allocated to a treatment sequence with normal diet plus 40 g/day of commercially available dark chocolate in tablet (cocoa solids >85%, cocoa mass, fat-reduced cocoa, cocoa butter, sugar, and vanilla) or normal diet for 30 days. The content of total polyphenols in the dark chocolate employed in our study was 799 μg GAE/ml.

Blood levels of CK, LDH, myoglobin, total polyphenols, and oxidative stress biomarkers were assessed at baseline and at 30 days after the last ingestion of chocolate. During the trial, participants were required to follow a diet adjusted according to their anthropometric and clinical characteristics and to the amount of calories coming from chocolate intake; furthermore, participants were restrained by having foods with high polyphenol content (blueberry, sweet cherry, strawberry, blackberry, red raspberry, chestnut, black tea, green tea, pure apple juice, hazelnut, red wine, and pomegranate juice) and/or additional chocolate.

Blood samples were collected in the morning (between 08:00 and 09:00 hours) after a fasting period of 8h at baseline and 30 days after the last ingestion of chocolate.

2.2. Randomisation and Blinding. An individual not involved in the study assigned codes to the study treatments, randomly allocated the participants to a treatment sequence with normal diet plus dark chocolate or normal diet, and kept the key in a sealed envelope. The randomisation was carried out by a procedure based on a random numeric sequence. The authors and laboratory technicians were unaware of the treatment allocation.

2.3. Sample Size, Randomisation, and Blinding. Sample size calculation was computed with G' Power [18] based on preliminary data, by means of a two tailed one-sample Student t-test with Welch correction: 1,69 (d) as effect size for sNox2-dp, 0.05 (a) as type I error probability, and 0.90 as power 1-b. Therefore, at least 22 elite soccer players (11 athletes per group, allocation ratio = 1) need to be randomly assigned to dark chocolate implementation or normal diet.

2.4. Extraction of Phenolic Fraction from Chocolate and Total Polyphenol Content Evaluation. One g of chocolate was weighted, and fat was removed by using 1 ml of n-hexane. Polyphenols were extracted from the defatted pellet using a total volume of 3 ml (1 × 3 ml) with 80% (v/v) of acetone: water at 80°C. This aqueous acetone solution, which contained most of all polyphenols, was used for polyphenols analysis and for in vitro study.

Total polyphenol content in extracted phenolic fraction from chocolate was evaluated by a modified Folin−Ciocalteu colorimetric method [19] and in plasma samples by the Folin−Ciocalteu method according to Serafini et al. [20]. Results were expressed as μg gallic acid equivalent (GAE)/ml.

2.5. Extraction and Quantification of Catechin and Epicatechin from Chocolate. Catechin and epicatechin were extracted and quantified according to Gottumukkala et al. [21]. Briefly, about 10 g of chocolate sample was extracted with methanol on a hot water and all methanolic fractions were combined, filtered, and evaporated. Catechin and epicatechin stock solutions were prepared in methanol in the concentration range of 100–600 μg/ml. HPLC analysis was performed using an HPLC system (Agilent 1200 Infinity Series HPLC system, Santa Clara, USA). The column temperature was maintained at 30°C. The HPLC mobile phase was as follows: solution A, 0.1 ml of orthophosphoric acid dissolved in 900 ml of HPLC-grade water; solution B, acetonitrile. The mobile phase was run using a gradient elution: at the time of 0.01 minutes, 11% B; at the time of 30 minutes, 25% B; at the time of 35 to 39 minutes, 100% B; and at the time of 40 to 50 minutes, 11% B. The mobile phase flow rate was 1.0 ml/minute, and the injection volume was 10 μl. The eluents were detected and analyzed at 280 nm.

2.6. Plasma Extraction and Quantification of Epicatechin. Plasma samples were extracted by the method described by Spadafranca et al. [22]. Briefly, 20 μl vitamin C-EDTA (200 mg vitamin C and 1 mg EDTA in 1 ml 0.4 mol/l Na$_2$HPO$_4$) and 20 μl glucuronidase/sulfatase type II (Sigma, St. Louis, MO) were added to 200 μl plasma and incubated at 37°C for 45 minutes. Flavonoids were extracted by addition of 500 μl acetonitrile, and the mixture was centrifuged at 10,000 g for 5 minutes at room temperature. After centrifugation, the supernatant was removed, dried under nitrogen, and reconstituted in the aqueous HPLC mobile phase. After centrifugation, 50 μl supernatant was injected into the HPLC column for separation, detection, and analysis.

The HPLC analysis was performed using an HPLC system (Agilent 1200 Infinity Series HPLC system, Santa Clara, USA). Separations were carried out at a flow rate of 1.5 ml/min with an isocratic mobile phase of 85% Na$_2$PO$_4$, 10 mol/l, pH 3, and 15% acetonitrile. Chromatograms were recorded at 279 nm, and plasma epicatechin identification was made by comparison of retention times with those of commercially available authentic (−)-epicatechin (Sigma, St. Louis, MO) through the same procedures as the plasma samples.

2.7. Determination of % HBA in Serum. Serum hydrogen peroxide (H$_2$O$_2$) breakdown activity (HBA) was measured with
2.8. Serum Nox2 Activation. Serum Nox2 was measured as soluble Nox2-derived peptide (sNox2dp) with an ELISA method, according to Pignatelli et al. [23].

2.9. H2O2 Production. Hydrogen peroxide (H2O2) was evaluated by a Colorimetric Detection Kit (Arbor Assays) and expressed as μmol/l. Intra-assay and interassay coefficients of variation were 2.1% and 3.7%, respectively.

2.10. Muscle Damage Markers. Serum creatine kinase (CK), lactate dehydrogenase (LDH), and myoglobin levels were analyzed using a commercial ELISA kit (Antibodies, Germany; ELAab, China; DRG Instruments GmbH, Germany); the intra- and interassay coefficients were <10%.

2.11. In Vitro Study

2.11.1. Cell Culture and Reagents. The murine myoblast cell line C2C12 was cultured in DMEM/20% heat-inactivated foetal bovine serum (FBS), 2 mM glutamine, and 1% antibiotics (all Gibco) for expansion and maintenance of the undifferentiating state. When cultures reached 80% confluence, myogenic differentiation was induced by replacing the expansion media with DMEM/0.2% FBS. Afterwards, cells were stimulated with H2O2 (5 mM, Solarbio, Beijing, China) alone or in combination with cocoa-derived polyphenols (50, 100, and 150 μg/ml) for 30 minutes. Conditioned media were harvested and tested for the quantification of soluble Nox2 and H2O2 as described.

2.12. Statistical Methods. Continuous variables are reported as mean ± standard deviation unless otherwise indicated. Differences between categorical variables were tested using the χ² test. The crossover study data were analyzed for the assessment of treatment and period effects, by performing a split-plot ANOVA with one between-subject factor (treatment sequence) and two within-subject factors (period 1 vs 2; pre- vs post-treatment). The full model was considered, allowing for the assessment of all main effects and interactions. Pairwise comparisons were corrected by t-test for paired data. Bivariate analysis was performed with the Spearman linear regression test. Multiple linear regression analysis was performed using a forward selection. p < 0.05 was considered statistically significant. All analyses were carried out with SPSS V.18.0 (Armonk, USA).

3. Results

3.1. Cross-Sectional Study. Clinical characteristics of elite football players and controls are reported in Table 1. WBC, BMI, and HBA were higher in controls compared to elite athletes. Conversely, LDH, CK, myoglobin sNox2-dp, and H2O2 were higher in elite athletics compared to controls (Table 1). A simple linear regression analysis showed that sNox2-dp was associated with CK (R = 0.208; p = 0.03), LDH (R = 0.451; p < 0.001), and myoglobin (R = 0.237; p = 0.001) (Figures 1(a)-1(c)).

3.2. Randomized Controlled Trial. Total polyphenol, catechin, and epicatechin contents of dark chocolate are reported in Table 2.

Table 2: Total polyphenol content in dark chocolate.

No significant differences between clinical characteristics and biochemical parameters were found at baseline in the elite athlete groups allocated to dark chocolate intake and no dark chocolate intake (Table 3, Figures 2 and 3). Four athletes dropped out of the study to transfer to another team. After 30 days of training, the control group showed increased levels of sNox2-dp and H2O2 compared to baseline (from 18.9 ± 7.0 pg/ml to 34.6 ± 7.5 pg/ml, p < 0.0001, and from 38.7 ± 10.2 μM to 48.9 ± 4.3 μM, p < 0.0001, respectively) (Figures 2(a) and 2(b)). Conversely, HBA and plasma total polyphenols resulted to be unchanged (from 37.78 ±
27.8% to 43.7 ± 16.3%, \( p = 0.402 \), and from 152.6 ± 35.3 μg GAE/ml to 144.7 ± 48.06 μg GAE/ml, \( p = 0.573 \), respectively) (Figures 2(c) and 2(d)). The pairwise comparisons showed that sNox2-2 dp levels and \( \text{H}_2\text{O}_2 \) production did not change after 30 days of dark chocolate intake compared to baseline (from 19.5 ± 6.7 pg/ml to 23.55 ± 5.6 pg/ml, \( p = 0.224 \), and from 37.7 ± 6.7 μM to 32.6 ± 4.5 μM, \( p = 0.06 \), respectively) (Figures 2(a) and 2(b)). Conversely, HBA and plasma total polyphenols increased after treatment (from 34.9 ± 29.8% to 66.0 ± 7.3%, \( p = 0.003 \), and from 151.9 ± 44.2 μg GAE/ml to 187.1 ± 7.1 μg GAE/ml, \( p = 0.02 \), respectively) (Figures 2(c) and 2(d)).

A significant difference between the two treatments (no dark chocolate vs dark chocolate) was found regarding sNox2-2 dp (34.6 ± 7.5 pg/ml vs 23.55 ± 5.6 pg/ml, \( p = 0.002 \)) (Figure 2(a)), \( \text{H}_2\text{O}_2 \) production (48.9 ± 4.3 μM vs 32.6 ± 4.5 μM, \( p < 0.002 \)) (Figure 2(b)), HBA (43.7 ± 16.3% vs 66.0 ± 7.3%, \( p = 0.008 \)) (Figure 2(c)) and total polyphenols (144.7 ± 48.1 μg GAE/ml vs 187.1 ± 7.1 μg GAE/ml, \( p = 0.02 \)) (Figure 2(d)).

Serum muscle enzymes highlighted in the control group increased myoglobin levels (from 97.4 ± 40.8 ng/ml to 168.0 ± 20.2 ng/ml, \( p = 0.0004 \)), and there was no change in CK and LDH levels (from 363.0 ± 69.1 U/l to 341.1 ± 63.67 U/l, \( p = 0.475 \), and 384.7 ± 59.6 U/l to 367.5 ± 52.9 U/l, \( p = 0.06 \), respectively) (Figures 3(a)-3(c)). Conversely, we observed a significant decrease of CK (from 337.4 ± 36.5 U/l to 283.9 ± 41.0 U/l, \( p = 0.0007 \)) and LDH (from 381.6 ± 44.3 U/l to 273.4 ± 55.5 U/l, \( p = 0.0008 \)) (Figures 3(b) and 3(c)) after dark chocolate treatment. Myoglobin levels decreased without reaching statistical significance (from 105.8 ± 41.9 ng/ml to 81.4 ± 25.7 ng/ml, \( p = 0.06 \)) (Figure 3(a)).

### 4. Discussion

This study showed that (1) oxidative stress and markers of muscle damage are significantly increased in elite football players compared to controls and (2) chronic intake of dark chocolate is able to reduce oxidative stress and muscle damage biomarkers during elite football players’ training session.

The novel finding of the present study is the improvement of oxidative stress and muscle damage enzymes after 30 days by ingestion of dark chocolate in elite football athletes during intensive physical exercise. The effect of dark

chocolate supports the hypothesis that polyphenol content, in particular epicatechin, may be responsible for this effect. Accordingly, total polyphenol content and epicatechin plasma levels were increased in the group of athletes randomized for dark chocolate intake.

The scientific background of our research was based on the evidence that intensive physical exercise implies a wide range of multifaceted biological activities challenging the physiological homeostasis of the body. The relationship between exercise and oxidative stress is extremely complex and mainly depends on mode, frequency, intensity, and duration of exercise. On the one hand, several experimental and epidemiological evidences have underlined the key role of physical exercise (PE) in decreasing oxidative stress, especially if associated to aging, and to prevent and positively modulate cardiovascular-associated risk factors [24, 25]. It was suggested that the reduction of oxidative stress triggered by PE could be associated with the improvement of the nitric oxide function. Regular exercise was also recently demonstrated to activate eNOS and nitrite production and to reduce oxidative stress in spontaneously hypertensive rats [26]. Moreover, PE was suggested to exert cardioprotective effects in ischemic rats in which high-intensity interval training increases NO metabolite levels and reduce myocardial infarction [27]. Oppositely, other reports have demonstrated that exercise increases the production of ROS, particularly suggesting that high-intensity, but not moderate, physical exercise can cause redox imbalance overwhelming the antioxidant defense ability, leading to several types of injuries [12, 28–30]. These emerging data have nonnegligible theoretical and applicative implications.

According to this premise, professional training programs including those for elite football players could indirectly and physiologically induce oxidative stress in athletes.

Figure 2: sNox2-dp levels (a), H$_2$O$_2$ production (b), hydrogen peroxide breakdown activity (HBA) (c), and total polyphenol (d) before and 30 days after daily intake of 40 g of dark chocolate (grey line) or without dark chocolate (black line) in elite football players.
and significantly influence biological antioxidant patterns. Accordingly, in our cross-sectional study, we found an increase in Nox2 activation and H₂O₂ production with reduced antioxidant property as indicated by decreased HBA in elite football players compared to controls. Moreover, at the same time, we observed an increase in muscle damage markers such as CK, LDH, and myoglobin.

These aspects represent a serious issue since a recent study showed that levels of oxidative stress markers are directly correlated with markers of muscular damage in elite football players playing in the Italian Serie A league [1].

For this reason, dietary regimens including antioxidant supplementation are now considered important interventions able to counteract the hazardous effects of free radicals by increasing the antioxidant profile and regulating the equilibrium between oxidant and antioxidant species [31]. These beneficial effects were observed in both animals and healthy subjects and in other chronic conditions that are accompanied by enhanced levels of oxidative stress [31–33]. Supporting endogenous defences with oral antioxidant supplementation may represent a suitable noninvasive tool for preventing or reducing oxidative stress during intensive physical training. The protective effects against oxidative stress elicited by antioxidant-rich nutrients have been partially ascribable to the high content of polyphenols (a class of chemicals characterized by the presence of phenol units in their chemical structure). The best-characterized biological property of all flavonoids as for polyphenols in general is their ability to act as antioxidants, by inhibiting ROS accumulation by scavenging ROS or by inhibiting enzymes involved in ROS production or by enhancing the natural antioxidant defences [34, 35]. In particular, a recent study suggests that daily supplementation with flavonol-rich cocoa over 4 weeks may improve oxidative stress biomarkers as

Figure 3: Myoglobin (a), creatine kinase (CK) (b), and lactate dehydrogenase (LDH) (c) concentration before and 30 days after daily intake of 40 g of dark chocolate (grey line) or without dark chocolate (black line) in elite football players.
indicated by an increase in total GSH levels and a decrease in urinary F2-isoprostane excretion [30].

We planned to use this body of evidence as a benchmark for the development of new strategies in the setting of elite athlete training programs. In this interventional study, we thus demonstrated for the first time that polyphenol-rich nutrient supplementation of dark chocolate reduces exercise-induced oxidative stress and muscular injury biomarkers in elite football athletes.

The antioxidative effects induced by cocoa-derived polyphenols were also confirmed on skeletal muscle cells in vitro. Our experiments were conducted using concentrations of polyphenol extract relatively close to that achieved in blood circulation of athletes after dark chocolate intake. Notably, the lower dose of polyphenols was able to completely counter the effects of induced oxidative stress, restoring the physiological redox state in treated murine myoblasts.

In conclusion, the present study provides the first direct relationship between cocoa-based polyphenol-rich nutrient supplementation and the effect of high-intensity training on elite athletes’ antioxidant status. Based on our results, the development and improvement of training techniques focusing also on new nutrition strategies may help to reduce muscular damage in elite football players.

**Data Availability**

The data used to support the findings of this study are available from the corresponding author upon request.

**Ethical Approval**

The institutional review board approved this study (C.E. 4662), and the randomized controlled trial was registered on ClinicalTrials.gov (Identifier: NCT03288623).

**Conflicts of Interest**

The authors declare that they have no conflict of interest.

**Authors’ Contributions**

Giacomo Frati, Roberto Carnevale, Elena Cavarretta, and Mariangela Peruzzi have equal contribution to this work.
